blood, swollen, moist, and is the seat of manifold sensations. If we apply to that activity of a given bodily area which consists in conveying sexually exciting stimuli to the mind the term *erotogenicity*, and if we reflect that the conclusions of our theory of sexuality have long accustomed us to the notion that certain other areas of the body—the *erotogenic zones*—may act as substitutes for the genitals and behave analogously to them, we then have only one step further to venture here. We can make up our minds to regard erotogenicity as a property common to all organs and are then justified in speaking of an increase or decrease in the degree of it in any given part of the body. It is possible that for every such change in the erotogenicity of the organs there is a parallel change in the libidinal cathexis in the ego. In such factors may lie the explanation of what is at the bottom of hypochondria and what it is that can have upon the distribution of the libido the same effect as actual organic disease.

We see that, if we follow out this line of thought, we encounter the problem not only of hypochondria, but of the other *actual neuroses*—neurasthenia and anxiety-neurosis. Let us therefore stop at this point. It is not within the scope of a purely psychological inquiry to penetrate so far behind the frontiers of physiological research. Let us only mention that from this point of view we may surmise that the relation of hypochondria to paraphrenia is similar to that of the other actual neuroses to hysteria and the obsessional neurosis: which is as much as to say that it is dependent on the ego-libido as the others are on the object-libido, and that hypochondriacal anxiety, emanating from the ego-libido, is the counterpart to neurotic anxiety. Further: since we are already familiar with the idea that the mechanism of disease and symptom-formation in the transference neuroses, the passage from introversion to regression, is to be connected with a damming-up of the object-libido,<sup>1</sup> we may come to closer quarters with the conception of a damming-up of the ego-libido also and may bring this conception into relation with the phenomena of hypochondria and paraphrenia.

Of course, curiosity will here suggest the question why such a damming-up of libido in the ego should be experienced as "painful." There I shall content myself with the answer that *pain* is in general the expression of in-

<sup>1</sup> Cf. Types of Neurotic Nosogenesis, *Collected Papers*, Vol. II.

creased tension, and thus a *quantity* of the material event is, here as elsewhere, transformed into the *quality* of "pain" in the mind; nevertheless, it may be not the absolute amount of the physical process which is decisive for the development of pain, but rather a certain function of this absolute amount. At this point we may even venture to touch on the question: whence does that necessity arise that urges our mental life to pass on beyond the limits of narcissism and to attach the libido to objects? The answer which would follow from our line of thought would once more be that we are so impelled when the cathexis of the ego with libido exceeds a certain degree. A strong egoism is a protection against disease, but, in the last resort, we must begin to love in order that we may not fall ill, and must fall ill if, in consequence of frustration, we cannot love. Somewhat after this fashion does Heine conceive of the psychogenesis of the Creation:

*Krankheit ist wohl der letzte Grund  
Des ganzen Schöpferdrangs gewesen;  
Erschaffend konnte ich genesen,  
Erschaffend wurde ich gesund.<sup>1</sup>*

We have recognized our mental apparatus above all as a device for mastering excitations which would otherwise be felt as unpleasant or would have pathogenic effects. The "working-over" of stimuli in the mind accomplishes wonders for the internal discharge of excitations which are incapable of direct discharge outwards, or for which such a discharge is, for the moment, undesirable. Now it is in the first instance a matter of indifference whether the objects of this internal process of "working-over" are real or imaginary. The difference does not appear till later, when the turning of the libido towards unreal objects (introversion) has led to a damming-up. The megalomania of paraphrenics permits a similar internal working-over of the libido which has returned to the ego to be made; perhaps it is only when this process fails that the damming-up of the libido in the ego becomes pathogenic and starts the process of recovery which impresses us as being the disease itself.

I shall try here to penetrate a little further into the mechanism of paraphrenia and to put together those conceptions which today seem to me worthy of consideration. The difference

between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but returns to the ego; the megalomania then represents the mastery of this volume of libido, and thus corresponds with the introversion on to the phantasy-creations that is found in the transference neuroses; the hypochondria of paraphrenia, which is homologous to the anxiety of the transference neuroses, arises from a failure of this effort in the mental apparatus. We know that the anxiety of the neuroses can be relieved by further mental "working-over," e.g., by conversion, reaction-formation or defence-formation (phobia). The corresponding process in paraphrenics is the effort towards recovery, to which the striking phenomena of the disease are due. Since frequently, if not usually, an only partial detachment of the libido from objects accompanies paraphrenia, we can distinguish in the clinical picture three groups of phenomena: (1) those representing such remains as there may be of a normal state or of neurosis (phenomena of a residual nature); (2) those representing the morbid process (the detachment of the libido from its objects and, further, megalomania, hypochondria, affective disturbance, and every kind of regression); (3) those representing an attempt at recovery. In (3) the libido is once more attached to objects, after the manner of an hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis takes place from another level and under other conditions than the primary one. The difference between the transference neurosis arising in this way and the corresponding formations where the ego is normal would afford us the deepest insight into the structure of our mental apparatus.

A third way in which we may study narcissism is by observing the behaviour of human beings in love, with its manifold differentiations in man and woman. In much the same way as the object-libido at first concealed from us the ego-libido, so in considering the object-choice of the child (and the adolescent) we first noticed that the sources from which he takes his sexual objects are his experiences of gratification. The first auto-erotic sexual gratifications are experienced in connection with vital functions in the service of self-preservation. The sexual instincts are at the outset supported upon the ego-instincts; only later do they be-

<sup>1</sup> Disease at bottom brought about  
Creative urgency—for, creating,  
I soon could feel the pain abating,  
Creating, I could work it out.

come independent of these, and even then we have an indication of that original dependence in the fact that those persons who have to do with the feeding, care, and protection of the child become his earliest sexual objects: that is to say, in the first instance the mother or her substitute. Side by side with this type and source of object-choice, which may be called the *anacletic* type, a second type, the existence of which we had not suspected, has been revealed by psycho-analytic investigation. We have found, especially in persons whose libidinal development has suffered some disturbance, as in perverts and homosexuals, that in the choice of their love-object they have taken as their model not the mother but their own selves. They are plainly seeking themselves as a love-object and their type of object-choice may be termed *narcissistic*. This observation provides us with our strongest motive for regarding the hypothesis of narcissism as a necessary one.

Now this does not mean that human beings are to be divided into two sharply differentiated groups, according as their object-choice conforms to the anacletic or to the narcissistic type; we rather assume that both kinds of object-choice are open to each individual, though he may show a preference for one or the other. We say that the human being has originally two sexual objects: himself and the woman who tends him, and thereby we postulate a primary narcissism in everyone, which may in the long run manifest itself as dominating his object-choice.

Further, the comparison of man and woman shows that there are fundamental differences between the two in respect of the type of object-choice, although these differences are, of course, not universal. Complete object-love of the anacletic type is, properly speaking, characteristic of the man. It displays the marked sexual over-estimation which is doubtless derived from the original narcissism of the child, now transferred to the sexual object. This sexual over-estimation is the origin of the peculiar state of being in love, a state suggestive of a neurotic compulsion, which is thus traceable to an impoverishment of the ego in respect of libido in favour of the love-object. A different course is followed in the type most frequently met with in women, which is probably the purest and truest feminine type. With the development of puberty, the maturing of the female sexual organs, which up till then have been in a condition of latency, seems to

bring about an intensification of the original narcissism, and this is unfavourable to the development of a true object-love with its accompanying sexual over-estimation; there arises in the woman a certain self-sufficiency (especially when there is a ripening into beauty) which compensates her for the social restrictions upon her object-choice. Strictly speaking, such women love only themselves with an intensity comparable to that of the man's love for them. Nor does their need lie in the direction of loving, but of being loved; and that man finds favour with them who fulfils this condition. The importance of this type of woman for the erotic life of mankind must be recognized as very great. Such women have the greatest fascination for men, not only for aesthetic reasons, since as a rule they are the most beautiful, but also because of certain interesting psychological constellations. It seems very evident that one person's narcissism has a great attraction for those others who have renounced part of their own narcissism and are seeking after object-love; the charm of a child lies to a great extent in his narcissism, his self-sufficiency and inaccessibility, just as does the charm of certain animals which seem not to concern themselves about us, such as cats and the large beasts of prey. In literature, indeed, even the great criminal and the humorist compel our interest by the narcissistic self-importance with which they manage to keep at arm's length everything which would diminish the importance of their ego. It is as if we envied them their power of retaining a blissful state of mind—an unassailable libidoposition which we ourselves have since abandoned. The great charm of the narcissistic woman has, however, its reverse side; a large part of the dissatisfaction of the lover, of his doubts of the woman's love, of his complaints of her enigmatic nature, have their root in this incongruity between the types of object-choice.

Perhaps it is not superfluous to give an assurance that, in this description of the feminine form of erotic life, no tendency to depreciate woman has any part. Apart from the fact that tendentiousness is alien to me, I also know that these different lines of development correspond to the differentiation of functions in a highly complicated biological connection; further, I am ready to admit that there are countless women who love according to the masculine type and who develop the over-estimation of the sexual object so characteristic of that type.

Even for women whose attitude towards the man remains cool and narcissistic, there is a way which leads to complete object-love. In the child to whom they give birth, a part of their own body comes to them as an object other than themselves, upon which they can lavish out of their narcissism complete object-love. Other women again do not need to wait for a child in order to take the step in development from (secondary) narcissism to object-love. Before puberty, they have had feelings of a likeness to men and have developed to some extent on masculine lines; after this tendency has been cut short when feminine maturity is reached, they still retain the capacity of longing for a masculine ideal which is really a survival of the boyish nature that they themselves once owned.

We may conclude these suggestions with a short survey of the paths leading to object-choice.

A person may love:

- (1) According to the narcissistic type:
  - (a) What he is himself (actually himself),
  - (b) What he once was,
  - (c) What he would like to be,
  - (d) Someone who was once part of himself;
- (2) According to the anaclitic type:
  - (a) The woman who tends,
  - (b) The man who protects;

and those substitutes which succeed them one after another. The justification for inserting case (c) of the first type has yet to be demonstrated later on in our discussion.

The significance of narcissistic object-choice for homosexuality in men must be appraised in another connection.

The primary narcissism of the child assumed by us, which forms one of the hypotheses in our theories of the libido, is less easy to grasp by direct observation than to confirm by deduction from another consideration. If we look at the attitude of fond parents towards their children, we cannot but perceive it as a revival and reproduction of their own, long since abandoned narcissism. Their feeling, as is well known, is characterized by over-estimation, that sure indication of a narcissistic feature in object-choice which we have already appreciated. Thus they are impelled to ascribe to the child all manner of perfections which sober observation would not confirm, to gloss over and forget all his shortcomings—a tendency with which, indeed, the denial of childish sex-

uality is connected. Moreover, they are inclined to suspend in the child's favour the operation of all those cultural acquirements which their own narcissism has been forced to respect, and to renew in his person the claims for privileges which were long ago given up by themselves. The child shall have things better than his parents; he shall not be subject to the necessities which they have recognized as dominating life. Illness, death, renunciation of enjoyment, restrictions on his own will, are not to touch him; the laws of nature, like those of society, are to be abrogated in his favour; he is really to be the centre and heart of creation, "His Majesty the Baby," as once we fancied ourselves to be. He is to fulfil those dreams and wishes of his parents which they never carried out, to become a great man and a hero in his father's stead, or to marry a prince as a tardy compensation to the mother. At the weakest point of all in the narcissistic position, the immortality of the ego, which is so relentlessly assailed by reality, security is achieved by fleeing to the child. Parental love, which is so touching and at bottom so childish, is nothing but parental narcissism born again and, transformed though it be into object-love, it reveals its former character infallibly.

### III

The disturbances to which the original narcissism of the child is exposed, the reactions with which he seeks to protect himself from them, the paths into which he is thereby forced—these are themes which I shall leave on one side, as an important field for work which still awaits exploration; the most important of these matters, however, can be isolated from the rest and, as the *castration complex* (in the boy, anxiety concerning the penis; in the girl, envy of the penis), be treated in connection with the effect of early sexual intimidation. Elsewhere, psycho-analytic research leads us to vicissitudes undergone by the libidinal instincts in which they are isolated from, and in opposition to, the ego-instincts; but, where the castration complex is in question, our researches permit us to infer the existence of an epoch and a mental state in which the two groups of instincts are acting in harmony with each other, inseparably blent, as narcissistic interests. It is from this state of things that A. Adler has derived his conception of the *masculine protest*, which he has exalted almost to the position of the sole motive power concerned in the forma-

tion of neurosis and also of character, and which he conceives of as having its origin, not in a narcissistic, and therefore still libidinal, trend, but in a social valuation. Psycho-analytic research has, from the very beginning, recognized the existence and significance of the masculine protest, but has always regarded it, in opposition to Adler, as narcissistic in nature and derived from the castration complex. It appertains to the formation of character, into the genesis of which it enters along with many other factors, and it is completely inadequate to explain the problems of the neuroses, in which Adler will take account of nothing but the manner in which they serve the interests of the ego. I find it quite impossible to base the genesis of neurosis upon so narrow a foundation as the castration complex, however pre-eminent a part this may play in men amongst the resistances to the cure of a neurosis. Lastly, I know also of cases of neurosis in which the masculine protest, or in our sense the castration complex, plays no pathogenic part, or does not appear at all.

Observation of normal adults shows that their former megalomania has been subdued and that the mental characteristics from which we inferred their infantile narcissism have vanished. What has become of their ego libido? Are we to assume that the whole of it has passed over into object-cathexes? Such a possibility is plainly contrary to the whole trend of our argument; but in the psychology of repression we may find a clue to another answer to the question.

We have learnt that libidinal impulses are fated to undergo pathogenic repression if they come into conflict with the subject's cultural and ethical ideas. By this we do not ever mean: if the individual in question has a merely intellectual knowledge of the existence of these ideas; we always mean: if he recognizes them as constituting a standard for himself and acknowledges the claims they make on him. Repression, as we have said, proceeds from the ego; we might say with greater precision: from the self-respect of the ego. The very impressions, experiences, impulses, and desires that one man indulges or at least consciously elaborates in his mind will be rejected with the utmost indignation by another, or stifled at once even before they enter consciousness. The difference between the two, however—and here we have the conditioning factor in repression—can easily be expressed in terms of the libido-theory. We may say that the one man

has set up an *ideal* in himself by which he measures his actual ego, while the other is without this formation of an ideal. From the point of view of the ego, this formation of an ideal would be the condition of repression.

To this ideal ego is now directed the self-love which the real ego enjoyed in childhood. The narcissism seems to be now displaced on to this new ideal ego, which, like the infantile ego, deems itself the possessor of all perfections. As always where the libido is concerned, here again man has shown himself incapable of giving up a gratification he has once enjoyed. He is not willing to forgo his narcissistic perfection in his childhood; and if, as he develops, he is disturbed by the admonitions of others and his own critical judgment is awakened, he seeks to recover the early perfection, thus wrested from him, in the new form of an ego-ideal. That which he projects ahead of him as his ideal is merely his substitute for the lost narcissism of his childhood—the time when he was his own ideal.

This suggests that we should examine the relation between this forming of ideals and sublimation. Sublimation is a process that concerns the object-libido and consists in the instinct's directing itself towards an aim other than, and remote from, that of sexual gratification; in this process the accent falls upon the deflection from the sexual aim. Idealization is a process that concerns the *object*; by it that object, without any alteration in its nature, is aggrandized and exalted in the mind. Idealization is possible in the sphere of the ego-libido as well as in that of the object-libido. For example, the sexual over-estimation of an object is an idealization of it. In so far as sublimation is a process that concerns the instinct and idealization one that concerns the object, the two concepts are to be distinguished one from the other.

The formation of the ego-ideal is often confounded with sublimation, to the detriment of clear comprehension. A man who has exchanged his narcissism for the worship of a high ego-ideal has not necessarily on that account succeeded in sublimating his libidinal instincts. It is true that the ego-ideal requires such sublimation, but it cannot enforce it; sublimation remains a special process which may be prompted by the ideal but the execution of which is entirely independent of any such incitement. It is just in neurotics that we find the highest degrees of tension between the development of their ego-ideal and the measure

of their sublimation of primitive libidinal instincts, and in general it is far harder to convince the idealist of the inexpediency of the hiding-place found by his libido than the plain man whose demands in this respect are only moderate. Further, the formation of an ego-ideal and sublimation are quite differently related to the causation of neurosis. As we have learnt, the formation of the ideal increases the demands of the ego and is the most powerful factor favouring repression; sublimation is a way out, a way by which the claims of the ego can be met without involving repression.

It would not surprise us if we were to find a special institution in the mind which performs the task of seeing that narcissistic gratification is secured from the ego-ideal and that, with this end in view, it constantly watches the real ego and measures it by that ideal. If such an institution does exist, it cannot possibly be something which we have not yet discovered; we only need to recognize it, and we may say that what we call our *conscience* has the required characteristics. Recognition of this institution enables us to understand the so-called *delusions of observation* or, more correctly, of *being watched*, which are such striking symptoms in the paranoid diseases and may perhaps also occur as an isolated form of illness, or intercalated in a transference neurosis. Patients of this sort complain that all their thoughts are known and their actions watched and overlooked; they are informed of the functioning of this mental institution by voices which characteristically speak to them in the third person ("Now she is thinking of that again" . . . "now he is going out"). This complaint is justified—it describes the truth; a power of this kind, watching, discovering and criticizing all our intentions, does really exist; indeed, it exists with every one of us in normal life. The delusion of being watched presents it in a regressive form, thereby revealing the genesis of this function and the reason why the patient is in revolt against it.

For that which prompted the person to form an ego-ideal, over which his conscience keeps guard, was the influence of parental criticism (conveyed to him by the medium of the voice), reinforced, as time went on, by those who trained and taught the child and by all the other persons of his environment—an indefinite host, too numerous to reckon (fellow-men, public opinion).

Large quantities of libido which is essentially homosexual are in this way drawn into the

formation of the narcissistic ego-ideal and find outlet and gratification in maintaining it. The institution of conscience was at bottom an embodiment, first of parental criticism, and subsequently of that of society; a similar process takes place when a tendency towards repression develops out of a command or prohibition imposed in the first instance from without. The voices, as well as the indefinite number of speakers, are brought into the foreground again by the disease, and so the evolution of conscience is regressively reproduced. But the revolt against this *ensorial institution* springs from the person's desire (in accordance with the fundamental character of his illness) to liberate himself from all these influences, beginning with that of his parents, and from his withdrawal of homosexual libido from those influences. His conscience then encounters him in a regressive form as a hostile influence from without.

The lament of the paranoiac shows also that at bottom the self-criticism of conscience is identical with, and based upon, self-observation. That activity of the mind which took over the function of conscience has also enlisted itself in the service of introspection, which furnishes philosophy with the material for its intellectual operations. This must have something to do with the characteristic tendency of paranoiacs to form speculative systems.<sup>1</sup>

It will certainly be of importance to us if we can see in other fields evidence of the activity of this critically watching faculty, which becomes heightened into conscience and philosophic introspection. I would refer here to what Herbert Silberer has called the "functional phenomenon," one of the few indisputably valuable additions to the theory of dreams. Silberer, as is well known, has shown that in the states between sleeping and waking we can directly observe the translation of thoughts into visual images, but that in these circumstances we frequently have a presentation, not of a thought-content, but of the actual state of the mind (readiness, fatigue, etc.) of the person who is struggling with sleep. Similarly, Silberer has shown that often the end of a dream or some section of the dream-content signifies merely the dreamer's own perception of his sleeping and waking. He has thus demon-

<sup>1</sup> I should like to add, merely by way of suggestion, that the process of development and strengthening of this watching institution might contain within it the genesis later on of (subjective) memory and of the time-factor, the latter of which has no application to unconscious processes.

strated that self-observation—in the sense of the paranoiac's delusion of being watched—plays a part in dream-formation. This part is not invariable; probably I overlooked it because it does not appear in my own dreams to any great extent; in persons who are gifted philosophically, and therefore accustomed to introspection, it may become very clear.

We may here recall our discovery that dream-formation takes place under the sway of a censorship which compels distortion of the dream-thoughts. We did not picture this censorship as a special force, an entity, but we chose the term to designate a particular aspect of the repressive tendencies which control the ego; namely, their attitude towards the dream-thoughts. Penetrating further into the structure of the ego, we may recognize the *dream-censor* again in the ego-ideal and in the dynamic utterances of conscience. If this censor is to some extent on the alert even during sleep, we can understand that the necessary condition of its activity—self-observation and self-criticism—should contribute to the dream-content some such thoughts as these: "Now he is too sleepy to think . . . now he is waking up."<sup>2</sup>

At this point we may enter upon a discussion of the self-regarding attitude in normal persons and in neurotics.

First of all, the feeling of self-regard appears to us a measure of the ego; what various components go to make up that measure is irrelevant. Everything we possess or achieve, every remnant of the primitive feeling of omnipotence that experience has corroborated, helps to exalt the self-regard.

Applying our distinction between sexual and ego-instincts, we must recognize that the self-regard has a very intimate connection with the narcissistic libido. Here we are supported by two fundamental facts: that in paraphrenics the self-regard is exalted, while in the transference neuroses it is abased; and that where the erotic life is concerned not being loved lowers the self-regarding feelings, while being loved raises them. We have stated that to be loved is the aim and the satisfaction in a narcissistic object-choice.

Further, it is easy to observe that libidinal object-cathexis does not raise the self-regard. The effect of the dependence upon the loved object is to lower that feeling: the lover is

humble. He who loves has, so to speak, forfeited a part of his narcissism, which can only be replaced by his being loved. In all these respects the self-regarding feelings seem to remain in a relation to the narcissistic element in the erotic life.

The realization of impotence, of one's own inability to love in consequence of mental or physical disorder, has an exceedingly lowering effect upon the self-regard. Here, as I judge, we shall find one of the sources of the feelings of inferiority of which patients suffering from the transference neuroses so readily complain to us. The main source of these feelings is, however, the impoverishment of the ego, due to the withdrawal from it of extraordinarily large libidinal cathexes—due, that is to say, to the injury sustained by the ego through the sexual trends which are no longer subject to control.

A. Adler is right in maintaining that a person's realization of organic inferiorities in himself acts as a spur upon an active mental life, and produces by way of over-compensation a higher degree of ability. But it would be altogether an exaggeration if, following this lead of Adler's, we tried to prove that every fine achievement was conditioned by an original organic inferiority. Not all artists are handicapped with bad eyesight, nor did all orators originally stammer. And there are plenty of instances of excellent achievements springing from superior organic endowment. In the aetiology of neurosis, organic inferiority and imperfect development play an insignificant part, much the same as that played by actual perceptual material in the formation of dreams. The neurosis makes use of such inferiorities as a pretext, just as it does of all other suitable factors. So surely as we credit the assertion of one neurotic patient that it was inevitable that she should fall ill, since she is ugly, deformed, or lacking in charm and so no one could love her, the very next neurotic will convince us of our error; for she remains the victim of her neurosis and her aversion to sexuality, although she seems to be desirable, and indeed more desired than the average woman. The majority of hysterical women are among the attractive and even beautiful representatives of their sex, while, on the other hand, the frequency of ugliness, organic infirmities, and defects in the lower classes of society does not increase the incidence of neurotic illness amongst them.

The relations existing between self-regard and erotism (libidinal object-cathexes) may be

<sup>2</sup> I cannot here determine whether the differentiation of the censorial function from the rest of the ego is capable of forming the basis of the philosophic distinction between consciousness and self-consciousness.

expressed in the following formula: two cases must be distinguished—in the first, the erotic cathexes are *ego-syntonic, in accordance with the ego-tendencies*; in the second, on the contrary, those cathexes have suffered repression. In the former case (where the path taken by the libido is acceptable to the ego), love takes its place among all the other activities of the ego. Love in itself, in the form of longing and deprivation, lowers the self-regard; whereas to be loved, to have love returned, and to possess the beloved object, exalts it again. When the libido is repressed, the erotic cathexis is felt as a severe depletion of the ego, the satisfaction of love is impossible, and the re-enrichment of the ego can be effected only by a withdrawal of the libido from its objects. The return of the libido from the object to the ego and its transformation into narcissism represents, as it were, the restoration of a happy love, and, conversely, an actual happy love corresponds to the primal condition in which object-libido and ego-libido cannot be distinguished.

Perhaps the importance of the subject, and the difficulty in surveying it, may be my excuse for adding a few remarks that are rather loosely strung together.

The development of the ego consists in a departure from the primary narcissism and results in a vigorous attempt to recover it. This departure is brought about by means of the displacement of libido to an ego-ideal imposed from without, while gratification is derived from the attainment of this ideal.

At the same time, the ego has put forth its libidinal object-cathexes. It becomes impoverished in consequence both of these cathexes and of the formation of the ego-ideal, and it enriches itself again both by gratification of its object love and by fulfilling its ideal.

Part of the self-regard is primary—the residue of childish narcissism; another part arises out of such omnipotence as experience corroborates (the fulfilment of the ego-ideal); whilst a third part proceeds from gratification of object-libido.

The ego-ideal has imposed severe conditions upon the gratification of libido through objects, for, by means of its censorship, it rejects some of them as incompatible with itself. Where no such ideal has been formed, the sexual trend in question makes its appearance unchanged in the personality in the form of a perversion. As in childhood, to be his own ideal once more, where sexual tendencies are concerned, is the happiness that man strives to attain.

The state of being in love consists in a flowing-over of ego-libido to the object. This state has the power to remove repressions and to restore perversions. It exalts the sexual object to the position of sexual ideal. Since, in cases where the love is of the anaclitic or object type, this state results from the fulfilment of infantile conditions of love, we may say that whatever fulfils this condition of love becomes idealized.

The sexual ideal may enter into an interesting auxiliary relation to the ego-ideal. Where narcissistic gratification encounters actual hindrances, the sexual ideal may be used as a substitutive gratification. In such a case a person loves (in conformity with the narcissistic type of object-choice) someone whom he once was and no longer is, or else someone who possesses excellences which he never had at all (cf. above, (c)). The parallel formula to that given above runs thus: whoever possesses an excellence which the ego lacks for the attainment of its ideal, becomes loved. This expedient is of special importance for the neurotic, whose ego is depleted by his excessive object-cathexes and who on that account is unable to attain to his ego ideal. He then seeks a way back to narcissism from his prodigal expenditure of libido upon objects, by choosing a sexual ideal after the narcissistic type which shall possess the excellences to which he cannot attain. This is the cure by love, which he generally prefers to cure by analysis. Indeed, he cannot believe in any other curative mechanism; he usually brings expectations of this sort with him to the treatment and then directs them towards the person of the physician. The patient's incapacity for love, an incapacity resulting from his extensive repressions, naturally stands in the way of such a method of cure. When, by means of the treatment, he has been partially freed from his repressions, we are frequently met by the unintended result that he withdraws from further treatment in order to choose a love-object, hoping that life with the beloved person will complete his recovery. We might be satisfied with this result, if it did not bring with it all the dangers of an overwhelming dependence upon this helper in his need.

The ego ideal is of great importance for the understanding of group psychology. Besides its individual side, this ideal has a social side; it is also the common ideal of a family, a class, or a nation. It not only binds the narcissistic libido, but also a considerable amount of the person's homosexual libido, which in this way becomes turned back into the ego. The dis-

satisfaction due to the non-fulfilment of this ideal liberates homosexual libido, which is transformed into sense of guilt (dread of the community). Originally this was a fear of punishment by the parents, or more correctly, the dread of losing their love; later the parents are replaced by an indefinite number of fellow-men. This helps us to understand why it is that

paranoia is frequently caused by a wounding of the ego, by a frustration of the gratification desired within the sphere of the ego-ideal, and also to understand the coincidence of ideal-formation and sublimation in the ego-ideal, as well as the demolition of sublimations and possible transformation of ideals in paraphrenic disorders.

# Instincts and Their Vicissitudes<sup>1</sup>

The view is often defended that sciences should be built up on clear and sharply defined basal concepts. In actual fact no science, not even the most exact, begins with such definitions. The true beginning of scientific activity consists rather in describing phenomena and then in proceeding to group, classify, and correlate them. Even at the stage of description, it is not possible to avoid applying certain abstract ideas to the material in hand, ideas derived from various sources and certainly not the fruit of the new experience only. Still more indispensable are such ideas—which will later become the basal concepts of the science—as the material is further elaborated. They must at first necessarily possess some measure of uncertainty; there can be no question of any clear delimitation of their content. So long as they remain in this condition, we come to an understanding about their meaning by repeated references to the material of observation, from which we seem to have deduced our abstract ideas, but which is, in point of fact, subject to them. Thus, strictly speaking, they are in the nature of conventions; although everything depends on their being chosen in no arbitrary manner, but determined by the important relations they have to the empirical material—relations that we seem to divine before we can clearly recognize and demonstrate them. It is only after more searching investigation of the field in question that we are able to formulate with increased clarity the scientific concepts underlying it, and progressively so to modify these concepts that they become widely applicable and at the same time consistent logically. Then, indeed, it may be time to immure them in definitions. The progress of science, however, demands a certain elasticity even in these definitions. The science of physics furnishes an excellent illustration of the way in which even those basal concepts that are firmly established in the form of definitions are constantly being altered in their content.

A conventional but still rather obscure basal concept of this kind, which is nevertheless indispensable to us in psychology, is that of an *instinct*. Let us try to ascertain what is com-

prised in this conception by approaching it from different angles.

First, from the side of physiology. This has given us the concept of *stimuli* and the scheme of the reflex arc, according to which a stimulus applied *from the outer world* to living tissue (nervous substance) is discharged by action *towards the outer world*. The action answers the purpose of withdrawing the substance affected from the operation of the stimulus, removing it out of range of the stimulus.

Now what is the relation between *instinct* and *stimulus*? There is nothing to prevent our including the concept of *instinct* under that of *stimulus* and saying that an instinct is a stimulus to the mind. But we are immediately set on our guard against treating instinct and mental stimulus as one and the same thing. Obviously, besides those of instinctual origin, there are other stimuli to the mind which behave far more like physiological stimuli. For example, a strong light striking upon the eye is not a stimulus of instinctual origin; it is one, however, when the mucous membrane of the oesophagus becomes parched or when a gnawing makes itself felt in the stomach.<sup>2</sup>

We have now obtained material necessary for discriminating between stimuli of instinctual origin and the other (physiological) stimuli which operate on our minds. First, a stimulus of instinctual origin does not arise in the outside world but from within the organism itself. For this reason, it has a different mental effect and different actions are necessary in order to remove it. Further, all that is essential in an external stimulus is contained in the assumption that it acts as a single impact, so that it can be discharged by a single appropriate action—a typical instance being that of motor flight from the source of stimulation. Of course, these impacts may be repeated and their force may be cumulative, but that makes no difference to our notion of the process and to the conditions necessary in order that the stimulus may be dispelled. An instinct, on the other hand, never acts as a momentary impact but always as a constant force. As it makes its

<sup>1</sup> *Collected Papers*, IV; first published in *Zeitschrift*, Vol. III (1915); reprinted in *Sammlung*, 4th Series.

<sup>2</sup> Assuming, of course, that these internal processes constitute the organic basis of the needs described as *thirst* and *hunger*.

attack not from without but from within the organism, it follows that no flight can avail against it. A better term for a stimulus of instinctual origin is a *need*; that which does away with this need is *satisfaction*. This can be attained only by a suitable (adequate) alteration of the inner source of stimulation.

Let us imagine ourselves in the position of an almost entirely helpless living organism, as yet unorientated in the world and with stimuli impinging on its nervous tissue. This organism will soon become capable of making a first discrimination and a first orientation. On the one hand, it will detect certain stimuli which can be avoided by an action of the muscles (flight)—these it ascribes to an outside world; on the other hand, it will also be aware of stimuli against which such action is of no avail and whose urgency is in no way diminished by it—these stimuli are the tokens of an inner world, the proof of instinctual needs. The perceptive substance of the living organism will thus have found in the efficacy of its muscular activity a means for discriminating between *outer* and *inner*.

We thus find our first conception of the essential nature of an instinct by considering its main characteristics, its origin in sources of stimulation within the organism and its appearance as a constant force, and thence we deduce one of its further distinguishing features, namely, that no actions of flight avail against it. Now, in making these remarks, we cannot fail to be struck by a fact which compels us to a further admission. We do not merely accept as basal concepts certain conventions which we apply to the material we have acquired empirically, but we also make use of various complicated postulates to guide us in dealing with psychological phenomena. We have already cited the most important of these postulates; it remains for us expressly to lay stress upon it. It is of a biological nature, and makes use of the concept of *purpose* (one might say, of adaptation of the means to the end) and runs as follows: the nervous system is an apparatus having the function of abolishing stimuli which reach it, or of reducing excitation to the lowest possible level: an apparatus which would even, if this were feasible, maintain itself in an altogether unstimulated condition. Let us for the present not take exception to the indefiniteness of this idea and let us grant that the task of the nervous system is—broadly speaking—to *master stimuli*. We see then how greatly the simple physiological reflex scheme

is complicated by the introduction of instincts. External stimuli impose upon the organism the single task of withdrawing itself from their action: this is accomplished by muscular movements, one of which reaches the goal aimed at and, being the most appropriate to the end in view, is thenceforward transmitted as an hereditary disposition. Those instinctual stimuli which emanate from within the organism cannot be dealt with by this mechanism. Consequently, they make far higher demands upon the nervous system and compel it to complicated and inter-dependent activities, which effect such changes in the outer world as enable it to offer satisfaction to the internal source of stimulation; above all, instinctual stimuli oblige the nervous system to renounce its ideal intention of warding off stimuli, for they maintain an incessant and unavoidable afflux of stimulation. So we may probably conclude that instincts and not external stimuli are the true motive forces in the progress that has raised the nervous system, with all its incomparable efficiency, to its present high level of development. Of course there is nothing to prevent our assuming that the instincts themselves are, at least in part, the precipitates of different forms of external stimulation, which in the course of phylogenesis have effected modifications in the organism.

Then when we find further that the activity of even the most highly developed mental apparatus is subject to the pleasure-principle, i.e., is automatically regulated by feelings belonging to the pleasure-“pain” series, we can hardly reject the further postulate that these feelings reflect the manner in which the process of mastering stimuli takes place. This is certainly so in the sense that “painful” feelings are connected with an increase and pleasurable feelings with a decrease in stimulation. Let us, however, be careful to preserve this assumption in its present highly indefinite form, until we succeed, if that is possible, in discovering what sort of relation exists between pleasure and “pain,” on the one hand, and fluctuations in the quantities of stimuli affecting mental life, on the other. It is certain that many kinds of these relations are possible, some of them by no means simple.

If now we apply ourselves to considering mental life from a biological point of view, an *instinct* appears to us as a borderland concept between the mental and the physical, being both the mental representative of the stimuli emanating from within the organism and penetrating to the mind, and at the same time a

measure of the demand made upon the energy of the latter in consequence of its connection with the body.

We are now in a position to discuss certain terms used in reference to the concept of an instinct, for example, its impetus, its aim, its object and its source.

By the *impetus* of an instinct we understand its motor element, the amount of force or the measure of the demand upon energy which it represents. The characteristic of impulsion is common to all instincts, is, in fact, the very essence of them. Every instinct is a form of activity; if we speak loosely of passive instincts, we can only mean those whose aim is passive.

The *aim* of an instinct is in every instance satisfaction, which can only be obtained by abolishing the condition of stimulation in the source of the instinct. But although this remains invariably the final goal of every instinct, there may yet be different ways leading to the same goal, so that an instinct may be found to have various nearer or intermediate aims, capable of combination or interchange. Experience permits us also to speak of instincts which are *inhibited in respect of their aim*, in cases where a certain advance has been permitted in the direction of satisfaction and then an inhibition or deflection has occurred. We may suppose that even in such cases a partial satisfaction is achieved.

The *object* of an instinct is that in or through which it can achieve its aim. It is the most variable thing about an instinct and is not originally connected with it, but becomes attached to it only in consequence of being peculiarly fitted to provide satisfaction. The object is not necessarily an extraneous one: it may be part of the subject's own body. It may be changed any number of times in the course of the vicissitudes the instinct undergoes during life; a highly important part is played by this capacity for displacement in the instinct. It may happen that the same object may serve for the satisfaction of several instincts simultaneously, a phenomenon which Adler calls a *confluence* of instincts. A particularly close attachment of the instinct to its object is distinguished by the term *fixation*: this frequently occurs in very early stages of the instinct's development and so puts an end to its mobility, through the vigorous resistance it sets up against detachment.

By the *source* of an instinct is meant that somatic process in an organ or part of the body

from which there results a stimulus represented in mental life by an instinct. We do not know whether this process is regularly of a chemical nature or whether it may also correspond with the release of other, e.g., mechanical, forces. The study of the sources of instinct is outside the scope of psychology; although its source in the body is what gives the instinct its distinct and essential character, yet in mental life we know it merely by its aims. A more exact knowledge of the sources of instincts is not strictly necessary for purposes of psychological investigation; often the source may be with certainty inferred from the aims.

Are we to suppose that the different instincts which operate upon the mind, but of which the origin is somatic, are also distinguished by different qualities and act in the mental life in a manner qualitatively different? This supposition does not seem to be justified; we are much more likely to find the simpler assumption sufficient—namely, that the instincts are all qualitatively alike and owe the effect they produce only to the quantities of excitation accompanying them, or perhaps further to certain functions of this quantity. The difference in the mental effects produced by the different instincts may be traced to the difference in their sources. In any event, it is only in a later connection that we shall be able to make plain what the problem of the quality of instincts signifies.

Now what instincts and how many should be postulated? There is obviously a great opportunity here for arbitrary choice. No objection can be made to anyone's employing the concept of an instinct of play or of destruction, or that of a social instinct, when the subject demands it and the limitations of psychological analysis allow of it. Nevertheless, we should not neglect to ask whether such instinctual motives, which are in one direction so highly specialized, do not admit of further analysis in respect of their sources, so that only those primal instincts which are not to be resolved further could really lay claim to the name.

I have proposed that two groups of such primal instincts should be distinguished: the *self-preservative* or *ego*-instincts and the *sexual* instincts. But this proposition has not the weight of a necessary postulate, such as, for instance, our assumption about the biological *purpose* in the mental apparatus (see above); it is merely an auxiliary construction, to be retained only so long as it proves useful, and it will make little difference to the results of

our work of description and classification if we replace it by another. The occasion for it arose in the course of the evolution of psycho-analysis, which was first employed upon the psychoneuroses, actually upon the group designated *transference neuroses* (hysteria and obsessional neurosis); through them it became plain that at the root of all such affections there lies a conflict between the claims of sexuality and those of the ego. It is always possible that an exhaustive study of the other neurotic affections (especially of the narcissistic psychoneuroses, the schizophrenias) may oblige us to alter this formula and therewith to make a different classification of the primal instincts. But for the present we do not know what this new formula may be, nor have we met with any argument which seems likely to be prejudicial to the contrast between sexual and ego-instincts.

I am altogether doubtful whether work upon psychological material will afford any decisive indication for the distinction and classification of instincts. Rather it would seem necessary to apply to this material certain definite assumptions in order to work upon it, and we could wish that these assumptions might be taken from some other branch of knowledge and transferred to psychology. The contribution of biology on this point certainly does not run counter to the distinction between sexual and ego-instincts. Biology teaches that sexuality is not on a level with the other functions of the individual, for its *purposes* go beyond the individual, their content being the production of new individuals and the preservation of the species. It shows, further, that the relation existing between the ego and sexuality may be conceived of in two ways, apparently equally well justified: in the one, the individual is regarded as of prime importance, sexuality as one of his activities and sexual satisfaction as one of his needs; while in the other, the individual organism is looked upon as a transitory and perishable appendage to the quasi-immortal germ-plasm bequeathed to him by the race. The assumption that the sexual function differs from other bodily processes in virtue of special chemical processes is, I understand, also a postulate of the Ehrlich school of biological research.

Since a study of the instincts from the side of consciousness presents almost insuperable difficulties, psycho-analytic investigation of mental disturbances remains the principal source of our knowledge. The development of

this line of investigation, however, has necessarily produced hitherto information of a more or less definite nature only in regard to the sexual instincts, for it is this group in particular which can be observed in isolation, as it were, in the psychoneuroses. With the extension of psycho-analysis to other neurotic affections we may be sure that we shall find a basis for our knowledge of the ego-instincts also, though it would be optimistic to expect equally favourable conditions for observation in this further field of research.

An attempt to formulate the general characteristics of the sexual instincts would run as follows: they are numerous, emanate from manifold organic sources, act in the first instance independently of one another and only at a late stage achieve a more or less complete synthesis. The aim which each strives to attain is *organ-pleasure*; only when the synthesis is complete do they enter the service of the function of reproduction, becoming thereby generally recognizable as sexual instincts. At their first appearance, they support themselves upon the instincts of self-preservation, from which they only gradually detach themselves; in their choice of object, also, they follow paths indicated by the ego-instincts. Some of them remain throughout life associated with these latter and furnish them with libidinal components, which with normal functioning easily escape notice and are clearly recognizable only when disease is present. They have this distinctive characteristic—that they have in a high degree the capacity to act vicariously for one another and that they can readily change their objects. In consequence of the last-mentioned properties they are capable of activities widely removed from their original modes of attaining their aims (sublimation).

Our inquiry into the various vicissitudes which instincts undergo in the process of development and in the course of life must be confined to the sexual instincts, for these are the more familiar to us. Observation shows us that an instinct may undergo the following vicissitudes:

Reversal into its opposite,  
Turning round upon the subject,  
Repression,  
Sublimation.

Since I do not intend to treat of sublimation here, and since repression requires a special chapter to itself, it only remains for us to describe and discuss the two first points. Bearing in mind that there are tendencies which are

opposed to the instincts pursuing a straightforward course, we may regard these vicissitudes as modes of defence against the instincts.

The *reversal* of an instinct into its opposite may on closer scrutiny be resolved into two different processes: a change from active to passive, and a reversal of the content. The two processes, being essentially distinct, must be treated separately.

Examples of the first process are met with in the two pairs of opposites: sadism-masochism and scopophilia-exhibitionism. The reversal here concerns only the aims of the instincts. The passive aim (to be tortured, or looked at) has been substituted for the active aim (to torture, to look at). Reversal of content is found in the single instance of the change of love into hate.

The *turning round* of an instinct upon the subject is suggested to us by the reflection that masochism is actually sadism turned round upon the subject's own ego, and that exhibitionism includes the love of gazing at the subject's own body. Further, analytic observation leaves us in no doubt that the masochist also enjoys the *act* of torturing when this is being applied to himself, and the exhibitionist the exposing of someone in being exposed himself. So the essence of the process is the change of the object, while the aim remains unchanged.

We cannot fail to note, however, that in these examples turning round upon the subject's self and transformation from active to passive coincide or occur in one process. To elucidate the relation between the two processes, a more thorough investigation must be undertaken.

With the pair of opposites sadism-masochism, the process may be represented as follows:

(a) Sadism consists in the exercise of violence or power upon some other person as its object.

(b) This object is abandoned and replaced by the subject's self. Together with the turning round upon the self, the change from an active to a passive aim in the instinct is also brought about.

(c) Again another person is sought as object; this person, in consequence of the alteration which has taken place in the aim of the instinct, has to take over the original rôle of the subject.

Case (c) is the condition commonly termed *masochism*. Satisfaction follows in this case also by way of the original sadism, the passive ego placing itself in phantasy back in its former

situation, which, however, has now been given up to another subject outside the self. Whether there is, besides this, a more direct masochistic satisfaction is highly doubtful. A primary masochism not derived in the manner I have described from sadism, does not appear to be met with.<sup>1</sup> That it is not superfluous to make the assumption of stage (b) is quite clear when we observe the behaviour of the sadistic impulse in cases of obsessional neurosis. In these we have the turning upon the subject's self, without the attitude of passivity towards another: the reversal has only reached the second stage. Self-torment and self-punishment have arisen from the desire to torture, but not masochism. The active voice is changed, not into the passive, but into the reflexive middle voice.

The conception of sadism is made more complicated by the circumstance that this instinct, side by side with its general aim (or perhaps rather, within it), seems to press towards a quite special aim: the infliction of pain, in addition to subjection and mastery of the object. Now psycho-analysis would seem to show that the infliction of pain plays no part in the original aims sought by the instinct: the sadistic child takes no notice of whether or not it inflicts pain, nor is it part of its purpose to do so. But when once the transformation into masochism has taken place, the experience of pain is very well adapted to serve as a passive masochistic aim, for we have every reason to believe that sensations of pain, like other unpleasant sensations, extend into sexual excitation and produce a condition which is pleasurable, for the sake of which the subject will even willingly experience the unpleasantness of pain. Where once the suffering of pain has been experienced as a masochistic aim, it can be carried back into the sadistic situation and result in a sadistic aim of *inflicting pain*, which will then be masochistically enjoyed by the subject while inflicting pain upon others, through his identification of himself with the suffering object. Of course, in either case it is not the pain itself which is enjoyed, but the accompanying sexual excitement, and this is especially easy for the sadist. The enjoyment of pain would thus be a primary masochistic aim, which, however, can then also become the aim of the originally sadistic instinct.

In order to complete my exposition, I would add that pity cannot be described as a result

<sup>1</sup> *Additional Note*, 1924. In later works (cf. "The Economic Problem of Masochism," 1924, *Collected Papers*, II) relating to problems of instinctual life, I have expressed the opposite view.

of the reversal of the sadistic instinct, but necessitates the conception of a *reaction-formation* against that instinct (for the difference, see below).

Rather different and simpler results are afforded by the investigation of another pair of opposites, namely, those instincts whose aim is sexual gazing (scotophilia) and self-display (the *voyeur* and *exhibitionist* tendencies, as they are called in the language of the perversions). Here again we may postulate the same stages as in the previous instance: (a) scotophilia as an activity directed towards an extraneous object; (b) abandonment of the object and a turning of the scotophilic instinct towards a part of the subject's own person; therewith a transformation to passivity and the setting up of a new aim—that of being looked at; (c) the institution of a new subject to whom one displays oneself in order to be looked at. Here too, it is hardly possible to doubt that the active aim appears before the passive, that scotophilia precedes exhibitionism. But there is an important divergence from what happens in the case of sadism, in that we can recognize in the scotophilic instinct a yet earlier stage than that described as (a). That is to say, that at the beginning of its activity the scotophilic instinct is auto-erotic: it has indeed an object, but that object is the subject's own body. It is only later that the instinct comes (by way of comparison) to exchange this object for the analogous one of the body of another (stage (a)). Now this preliminary stage is interesting because it is the source of both the situations represented in the resulting pair of opposites, according to which element in the original situation is reversed. The following might serve as a scheme for the scotophilic instinct:

α Subject's looking at his own sexual organ	=	Subject's own sexual organ being looked at by himself
β Subject's looking at an extraneous object (active scotophilia)	γ	Subject's own sexual organ being looked at by another person (exhibitionism)

A preliminary stage of this kind is absent in sadism, which from the outset is directed upon an extraneous object, although it might not be altogether unreasonable to regard as such a stage the child's efforts to gain control of his limbs.<sup>1</sup>

With regard to both these instincts just ex-

<sup>1</sup> Cf. preceding footnote.

amined as examples, it must be said that transformation of them by a reversal from active to passive, and by a turning round upon the subject, never in fact concerns the whole amount of impelling force pertaining to the instinct. To some extent its earlier active direction always persists side by side with the later passive direction, even when the transformation is very extensive. The only correct description of the scotophilic instinct would be that all phases of its development, the auto-erotic, preliminary phase as well as its final active or passive form, co-exist alongside one another; and the truth of this statement becomes manifest if we base our opinion, not upon the actions which are prompted by the instinct, but upon the mechanism of its satisfaction. Perhaps yet another way of conceiving and representing the matter may be justified. We may split up the life of each instinct into a series of *thrusts*, distinct from one another in the time of their occurrence but each homogeneous within its own period, whose relation to one another is comparable to that of successive eruptions of lava. We can then perhaps picture to ourselves that the earliest and most primitive instinct-eruption persists in an unchanged form and undergoes no development at all. The next *thrust* would then from the outset have undergone a change of form, being turned, for instance, from active to passive, and it would then, with this new characteristic, be superimposed upon the earlier layer, and so on. So that, if we take a survey of the instinctual tendency from its beginning up to any given stopping-point, the succession of thrusts which we have described would present the picture of a definite development of the instinct.

The fact that, at that later period of development, the instinct in its primary form may be observed side by side with its (passive) opposite deserves to be distinguished by the highly appropriate name introduced by Bleuler: *ambivalence*.

These considerations regarding the developmental history of an instinct and the permanent character of the intermediate stages in it should make instinct-development more comprehensible to us. Experience shows that the degree of demonstrable ambivalence varies greatly in individuals, groups, and races. Marked ambivalence of an instinct in a human being at the present day may be regarded as an archaic inheritance, for we have reason to suppose that the part played in the life of the instincts by the active impulses in their original

form was greater in primitive times than it is on an average today.

We have become accustomed to call the early phase of the development of the ego, during which its sexual instincts find auto-erotic satisfaction, *narcissism*, without having so far entered into any discussion of the relation between auto-erotism and narcissism. It follows that, in considering the preliminary phase of the scopophilic instinct, when the subject's own body is the object of the scopophilia, we must place it under the heading of narcissism; it is a narcissistic formation. From this phase the active scopophilic instinct, which has left narcissism behind, is developed, while the passive scopophilic instinct, on the contrary, holds fast to the narcissistic object. Similarly, the transformation from sadism to masochism betokens a reversion to the narcissistic object, while in both cases the narcissistic (active) subject is exchanged by identification for another, extraneous ego. Taking into consideration the preliminary narcissistic stage of sadism constructed by us, we approach the more general view that those vicissitudes which consist in the instinct being turned round upon the subject's own ego and undergoing reversal from activity to passivity are dependent upon the narcissistic organization of the ego and bear the stamp of that phase. Perhaps they represent attempts at defence which at higher stages of the development of the ego are effected by other means.

At this point we may remember that so far we have discussed only two pairs of instincts and their opposites: sadism-masochism and scopophilia-exhibitionism. These are the best-known sexual instincts which appear in ambivalent forms. The other components of the later sexual function are at present too inaccessible to analysis for us to be able to discuss them in a similar way. In general we can assert of them that their activities are auto-erotic, i.e., their object becomes negligible in comparison with the organ which is their source, and as a rule the two coincide. The object of the scopophilic instinct, although it also in the first instance is a part of the subject's own body, nevertheless is not the eye itself; and with sadism the organic source, probably the musculature with its capacity for action, directly presupposes an object other than itself, even though that object be part of the subject's own body. In the auto-erotic instincts, the part played by the organic source is so decisive that, according to a plausible supposition of P. Fed-

ern and L. Jekels,<sup>1</sup> the form and function of the organ determine the activity or passivity of the instinct's aim.

The transformation of the *content* of an instinct into its opposite is observed in a single instance only—the changing of *love into hate*. It is particularly common to find both these directed simultaneously towards the same object, and this phenomenon of their co-existence furnishes the most important example of ambivalence of feeling.

The case of love and hate acquires a special interest from the circumstance that it resists classification in our scheme of the instincts. It is impossible to doubt the existence of a most intimate relation between these two contrary feelings and sexual life, but one is naturally unwilling to conceive of love as being a kind of special component-instinct of sexuality in the same way as are the others just discussed. One would prefer to regard loving rather as the expression of the whole sexual current of feeling, but this idea does not clear up our difficulties and we are at a loss how to conceive of an essential opposite to this striving.

Loving admits of not merely one, but of three antitheses. First there is the antithesis of loving—hating; secondly, there is loving—being loved; and, in addition to these, loving and hating together are the opposite of the condition of neutrality or indifference. The second of these two antitheses, loving—being loved, corresponds exactly to the transformation from active to passive and may be traced to a primal situation in the same way as the scopophilic instinct. This situation is that of *loving oneself*, which for us is the characteristic of narcissism. Then, according to whether the self as object or subject is exchanged for an extraneous one, there results the active aim of loving or the passive one of being loved, the latter remaining nearly related to narcissism.

Perhaps we shall come to a better understanding of the manifold opposites of loving if we reflect that our mental life as a whole is governed by *three polarities*, namely, the following antitheses:

Subject (ego)—Object (external world),  
Pleasure—Pain,  
Active—Passive.

The antithesis of ego—non-ego (outer), i.e., subject—object, is, as we have already said, thrust upon the individual being at an early stage, by the experience that it can abolish ex-

<sup>1</sup> *Zeitschrift*, Vol. I, (1913).

ternal stimuli by means of muscular action but is defenceless against those stimuli that originate in instinct. This antithesis remains sovereign above all in our intellectual activity and provides research with a fundamental situation which no amount of effort can alter. The polarity of pleasure—pain depends upon a feeling-series, the significance of which in determining our actions (will) is paramount and has already been emphasized. The antithesis of active and passive must not be confounded with that of ego-subject—external object. The relation of the ego to the outer world is passive in so far as it receives stimuli from it, active when it reacts to these. Its instincts compel it to a quite special degree of activity towards the outside world, so that, if we wished to emphasize the essence of the matter, we might say that the ego-subject is passive in respect of external stimuli, active in virtue of its own instincts. The antithesis of active—passive coalesces later with that of masculine—feminine, which, until this has taken place, has no psychological significance. The fusion of activity with masculinity and passivity with femininity confronts us, indeed, as a biological fact, but it is by no means so invariably complete and exclusive as we are inclined to assume.

The three polarities within the mind are connected with one another in various highly significant ways. There is a certain primal psychic situation in which two of them coincide. Originally, at the very beginning of mental life, the ego's instincts are directed to itself and it is to some extent capable of deriving satisfaction for them on itself. This condition is known as *narcissism*, and this potentiality for satisfaction is termed *auto-erotic*.<sup>1</sup> The outside world is at this time, generally speaking, not cathected with any interest and is indifferent for purposes of satisfaction. At this period, therefore, the ego-subject coincides with what is pleasurable and the outside world with what is indifferent (or even painful, as being a source of stimulation). Let us for the moment define *loving* as the re-

lation of the ego to its sources of pleasure: then the situation in which the ego loves itself only and is indifferent to the outside world illustrates the first of the polarities in which *loving* appeared.

In so far as it is auto-erotic, the ego has no need of the outside world, but, in consequence of experiences undergone by the instincts of self-preservation, it tends to find objects there and doubtless it cannot but for a time perceive inner instinctual stimuli as painful. Under the sway of the pleasure-principle, there now takes place a further development. The objects presenting themselves, in so far as they are sources of pleasure, are absorbed by the ego into itself, *introjected* (according to an expression coined by Ferenczi); while, on the other hand, the ego thrusts forth upon the external world whatever within itself gives rise to pain (see below: the mechanism of projection).

Thus the original *reality-ego*, which distinguished outer and inner by means of a sound objective criterion, changes into a purified *pleasure-ego*, which prizes above all else the quality of pleasure. For this pleasure-ego, the outside world is divided into a part that is pleasurable, which it has incorporated into itself, and a remainder that is alien to it. A part of itself it has separated off, and this it projects into the external world and regards as hostile. According to this new arrangement the congruence of the two polarities,

ego-subject with pleasure,

outside world with pain (or earlier with neutrality), is once more established.

When the stage of primary narcissism is invaded by the object, the second contrary attitude to that of love, namely, hate, attains to development.

As we have heard, the ego's objects are presented to it from the outside world in the first instance by the instincts of self-preservation, and it is undeniable also that hate originally betokens the relation of the ego to the alien external world with its afflux of stimuli. Neutrality may be classified as a special case of hate or rejection, after having made its appearance first as the forerunner of hate. Thus at the very beginning, the external world, objects and that which was hated were one and the same thing. When later on an object manifests itself as a source of pleasure, it becomes loved, but also incorporated into the ego, so that for the purified pleasure-ego the object once again coincides with what is extraneous and hated.

Now, however, we note that just as the an-

<sup>1</sup> Some of the sexual instincts are, as we know, capable of this auto-erotic satisfaction and so are adapted to be the channel for that development under the sway of the pleasure-principle which we shall describe later. The sexual instincts, which from the outset require an object, and the needs of the ego-instincts, which are never capable of auto-erotic satisfaction, interfere, of course, with this condition and prepare the way for progress. More, the primal narcissistic condition would not have been able to attain such a development were it not that every individual goes through a period of helplessness and dependence on fostering care, during which his urgent needs are satisfied by agencies outside himself and thereby withheld from developing along their own line.

tithesis love—indifference reflects the polarity ego—external world, so the second antithesis, love—hate, reproduces the polarity pleasure—pain, which is bound up with the former. When the purely narcissistic stage gives place to the object-stage, pleasure and pain denote the relations of the ego to the object. When the object becomes a source of pleasurable feelings, a motor tendency is set up which strives to bring the object near to and incorporate it into the ego; we then speak of the *attraction* exercised by the pleasure-giving object, and say that we *love* that object. Conversely, when the object is the source of painful feelings, there is a tendency which endeavours to increase the distance between object and ego and to repeat in relation to the former the primordial attempt at flight from the external world with its flow of stimuli. We feel a *repulsion* from the object, and hate it; this hate can then be intensified to the point of an aggressive tendency towards the object, with the intention of destroying it.

We might at a pinch say of an instinct that it loves the objects after which it strives for purposes of satisfaction, but to say that it hates an object strikes us as odd; so we become aware that the attitudes of love and hate cannot be said to characterize the relations of instincts to their objects, but are reserved for the relations of the ego as a whole to objects. But, if we consider a colloquial usage which is certainly full of meaning, we see that there is yet another limitation to the significance of love and hate. We do not say of those objects which serve the interests of self-preservation that we love them; rather we emphasize the fact that we need them, and perhaps add an element of a different kind in our relation to them by words which denote a much lesser degree of love—for example, *to be fond of*, *to like*, *to find agreeable*.

So the word *love* becomes shifted ever further into the sphere of the pure pleasure-relation existing between the ego and its object and finally attaches itself to sexual objects in the narrower sense and to those which satisfy the needs of sublimated sexual instincts. The discrimination of the ego-instincts from the sexual, a discrimination which we have imposed upon our psychology, is seen, therefore, to be in conformity with the spirit of our speech. Since we do not customarily say that the single sexual component-instinct loves its object, but see the most appropriate case in which to apply the word *love* in the relation of the ego to its sexual object, we learn from this fact that the

applicability of the word in this relation begins only with the synthesis of all the component-instincts under the primacy of the genitals and in the service of the function of reproduction.

It is noteworthy that in the use of the word *hate* no such intimate relation to sexual pleasure and the sexual function appears: on the contrary, the painful character of the relation seems to be the sole decisive feature. The ego hates, abhors, and pursues with intent to destroy all objects which are for it a source of painful feelings, without taking into account whether they mean to it frustration of sexual satisfaction or of gratification of the needs of self-preservation. Indeed, it may be asserted that the true prototypes of the hate-relation are derived not from sexual life, but from the struggle of the ego for self-preservation and self-maintenance.

So we see that love and hate, which present themselves to us as essentially antithetical, stand in no simple relation to each other. They did not originate in a cleavage of any common primal element, but sprang from different sources and underwent each its own development before the influence of the pleasure-pain relation constituted them antitheses to each other. At this point we are confronted with the task of putting together what we know of the genesis of love and hate.

Love originates in the capacity of the ego to satisfy some of its instincts auto-erotically through the obtaining of *organ-pleasure*. It is primarily narcissistic, is then transferred to those objects which have been incorporated in the ego, now much extended, and expresses the motor striving of the ego after these objects as sources of pleasure. It is intimately connected with the activity of the later sexual instincts and, when these have been completely synthesized, coincides with the sexual trend as a whole. The preliminary stages of love reveal themselves as temporary sexual aims, while the sexual instincts are passing through their complicated development. First amongst these we recognize the phase of incorporating or devouring, a type of love which is compatible with abolition of any separate existence on the part of the object, and which may therefore be designated *ambivalent*. At the higher stage of the pre-genital sadistic-anal organization, the striving after the object appears in the form of an impulse to mastery, in which injury or annihilation of the object is a matter of indifference. This form and preliminary stage of love is hardly to be distinguished from hate in its be-

haviour towards the object. Only when the genital organization is established does love become the antithesis of hate.

The relation of hate to objects is older than that of love. It is derived from the primal repudiation by the narcissistic ego of the external world whence flows the stream of stimuli. As an expression of the pain-reaction induced by objects, it remains in constant intimate relation with the instincts of self-preservation, so that sexual and ego-instincts readily develop an antithesis which repeats that of love and hate. When the sexual function is governed by the ego-instincts, as at the stage of the sadistic-anal organization, they impart the qualities of hate to the instinct's aim as well.

The history of the origin and relations of love makes us understand how it is that love so constantly manifests itself as ambivalent, i.e., accompanied by feelings of hate against the same object. This admixture of hate in love is to be traced in part to those preliminary stages of love which have not been wholly outgrown, and in part is based upon reactions of aversion and repudiation on the part of the ego-instincts which, in the frequent conflicts between the interests of the ego and those of love, can claim to be supported by real and actual motives. In both cases, therefore, the admix-

ture of hate may be traced to the source of self-preservative instincts. When a love-relationship with a given object is broken off, it is not infrequently succeeded by hate, so that we receive the impression of a transformation of love into hate. This descriptive characterization is amplified by the view that, when this happens, the hate which is motivated by considerations of reality is reinforced by a regression of the love to the sadistic preliminary stage, so that the hate acquires an erotic character and the continuity of a love-relation is ensured.

The third antithesis of love, the transformation of loving into being loved, represents the operation of the polarity of active and passive, and is to be judged in the same way as in scopophilia and sadism. We may sum up by saying that the essential feature in the vicissitudes undergone by instincts is *their subjection to the influences of the three great polarities that govern mental life*. Of these three polarities we might describe that of activity—passivity as the *biological*, that of ego—external world as the *real*, and finally that of pleasure—pain as the *economic* respectively.

That possible vicissitude undergone by an instinct which we call *repression* will form the subject of a further inquiry.

# Repression<sup>1</sup>

One of the vicissitudes an instinctual impulse may undergo is to meet with resistances the aim of which is to make the impulse inoperative. Under certain conditions, which we shall presently investigate more closely, the impulse then passes into the state of *repression*. If it were a question of the operation of an external stimulus, obviously flight would be the appropriate remedy; with an instinct, flight is of no avail, for the ego cannot escape from itself. Later on, rejection based on judgment (*condemnation*) will be found to be a good weapon against the impulse. Repression is a preliminary phase of condemnation, something between flight and condemnation; it is a concept which could not have been formulated before the time of psycho-analytic research.

It is not easy in theory to deduce the possibility of such a thing as repression. Why should an instinctual impulse suffer such a fate? For this to happen, obviously a necessary condition must be that attainment of its aim by the instinct should produce "pain" instead of pleasure. But we cannot well imagine such a contingency. There are no such instincts; satisfaction of an instinct is always pleasurable. We should have to assume certain peculiar circumstances, some sort of process which changes the pleasure of satisfaction into "pain".

In order the better to define repression we may discuss some other situations in which instincts are concerned. It may happen that an external stimulus becomes internal, for example, by eating into and destroying a bodily organ, so that a new source of constant excitation and increase of tension is formed. The stimulus thereby acquires a far-reaching similarity to an instinct. We know that a case of this sort is experienced by us as *physical pain*. The aim of this pseudo-instinct, however, is simply the cessation of the change in the organ and of the pain accompanying it. There is no other direct pleasure to be attained by cessation of the pain. Further, pain is imperative; the only things which can subdue it are the effect of some toxic agent in removing it and the influence of some mental distraction.

The case of physical pain is too obscure to

help us much in our purpose. Let us suppose that an instinctual stimulus such as hunger remains unsatisfied. It then becomes imperative and can be allayed by nothing but the appropriate action for satisfying it; it keeps up a constant tension of need. Anything like a repression seems in this case to be utterly out of the question.

So repression is certainly not an essential result of the tension produced by lack of satisfaction of an impulse being raised to an unbearable degree. The weapons of defence of which the organism avails itself to guard against that situation must be discussed in another connection.

Let us instead confine ourselves to the clinical experience we meet with in the practice of psycho-analysis. We then see that the satisfaction of an instinct under repression is quite possible; further, that in every instance such a satisfaction is pleasurable in itself, but is irreconcilable with other claims and purposes; it therefore causes pleasure in one part of the mind and "pain" in another. We see then that it is a condition of repression that the element of avoiding "pain" shall have acquired more strength than the pleasure of gratification. Psycho analytic experience of the transference neuroses, moreover, forces us to the conclusion that repression is not a defence-mechanism present from the very beginning, and that it cannot occur until a sharp distinction has been established between what is conscious and what is unconscious: that *the essence of repression lies simply in the function of rejecting and keeping something out of consciousness*. This conception of repression would be supplemented by assuming that, before the mental organization reaches this phase, the other vicissitudes which may befall instincts, e.g., reversal into the opposite or turning round upon the subject, deal with the task of mastering the instinctual impulses.

It seems to us now that, in view of the very great extent to which repression and the unconscious are correlated, we must defer probing more deeply into the nature of repression until we have learnt more about the structure of the various institutions in the mind—and about what differentiates consciousness from the un-

<sup>1</sup> *Collected Papers*, IV; first published in *Zeitschrift*, Vol. III (1915); reprinted in *Sammlung*, 4th Series.

conscious. Till we have done this, all we can do is to put together in purely descriptive fashion some characteristics of repression noted in clinical practice, even though we run the risk of having to repeat unchanged much that has been said elsewhere.

Now we have reason for assuming a *primal repression*, a first phase of repression, which consists in a denial of entry into consciousness to the mental (ideational) presentation of the instinct. This is accompanied by a *fixation*; the ideational presentation in question persists unaltered from then onwards, and the instinct remains attached to it. This is due to certain properties of unconscious processes of which we shall speak later.

The second phase of repression, *repression proper*, concerns mental derivatives of the repressed instinct-presentation, or such trains of thought as, originating elsewhere, have come into associative connection with it. On account of this association, these ideas experience the same fate as that which underwent primal repression. Repression proper, therefore, is actually an after-expulsion. Moreover, it is a mistake to emphasize only the rejection which operates from the side of consciousness upon what is to be repressed. We have to consider just as much the attraction exercised by what was originally repressed upon everything with which it can establish a connection. Probably the tendency to repression would fail of its purpose if these forces did not co-operate, if there were not something previously repressed ready to assimilate that which is rejected from consciousness.

Under the influence of study of the psychoneuroses, which brings before us the important effects of repression, we are inclined to overestimate their psychological content and to forget too readily that repression does not hinder the instinct-presentation from continuing to exist in the unconscious and from organizing itself further, putting forth derivatives and instituting connections. Really, repression interferes only with the relation of the instinct-presentation to one system of the mind, namely, to consciousness.

Psycho-analysis is able to show us something else which is important for understanding the effects of repression in the psychoneuroses. It shows us, for instance, that the instinct-presentation develops in a more unchecked and luxuriant fashion if it is withdrawn by repression from conscious influence. It ramifies like a fungus, so to speak, in the dark; and takes on

extreme forms of expression, which when translated and revealed to the neurotic are bound not merely to seem alien to him, but to terrify him by the way in which they reflect an extraordinary and dangerous strength of instinct. This illusory strength of instinct is the result of an uninhibited development of it in phantasy and of the damming-up consequent on lack of real satisfaction. The fact that this last result is bound up with repression points the direction in which we have to look for the true significance of the latter.

In reverting to the contrary aspect, however, let us state definitely that it is not even correct to suppose that repression withholds from consciousness all the derivatives of what was primally repressed. If these derivatives are sufficiently far removed from the repressed instinct-presentation, whether owing to the process of distortion or by reason of the number of intermediate associations, they have free access to consciousness. It is as though the resistance of consciousness against them was in inverse proportion to their remoteness from what was originally repressed. During the practice of the psycho-analytic method, we continually require the patient to produce such derivatives of what has been repressed as, in consequence either of their remoteness or of distortion, can pass the censorship of consciousness. Indeed, the associations which we require him to give, while refraining from any consciously directed train of thought or any criticism, and from which we reconstruct a conscious interpretation of the repressed instinct-presentation, are precisely derivatives of this kind. We then observe that the patient can go on spinning a whole chain of such associations, till he is brought up in the midst of them against some thought-formation, the relation of which to what is repressed acts so intensely that he is compelled to repeat his attempt at repression. Neurotic symptoms, too, must have fulfilled the condition referred to, for they are derivatives of the repressed, which has finally by means of these formations wrested from consciousness the right of way previously denied it.

We can lay down no general rule concerning the degree of distortion and remoteness necessary before the resistance of consciousness is abrogated. In this matter a delicate balancing takes place, the play of which is hidden from us; its mode of operation, however, leads us to infer that it is a question of a definite degree of intensity in the cathexis of the unconscious—

beyond which it would break through for satisfaction. Repression acts, therefore, in a *highly specific* manner in each instance; every single derivative of the repressed may have its peculiar fate—a little more or a little less distortion alters the whole issue. In this connection, it becomes comprehensible that those objects to which men give their preference, that is, their ideals, originate in the same perceptions and experiences as those objects of which they have most abhorrence, and that the two originally differed from one another only by slight modifications. Indeed, as we found in the origin of the fetish, it is possible for the original instinct-presentation to be split into two, one part undergoing repression, while the remainder, just on account of its intimate association with the other, undergoes idealization.

The same result as ensues from an increase or a decrease in the degree of distortion may also be achieved at the other end of the apparatus, so to speak, by a modification in the conditions producing pleasure and "pain." Special devices have been evolved, with the object of bringing about such changes in the play of mental forces that what usually gives rise to "pain" may on this occasion result in pleasure, and whenever such a device comes into operation the repression of an instinct-presentation that is ordinarily repudiated is abrogated. The only one of these devices which has till now been studied in any detail is that of joking. Generally the lifting of the repression is only transitory; the repression is immediately re-established.

Observations of this sort, however, suffice to draw our attention to some further characteristics of repression. Not only is it, as we have just explained, *variable* and *specific*, but it is also exceedingly *mobile*. The process of repression is not to be regarded as something which takes place once for all, the results of which are permanent, as when some living thing has been killed and from that time onward is dead; on the contrary, repression demands a constant expenditure of energy, and if this were discontinued the success of the repression would be jeopardized, so that a fresh act of repression would be necessary. We may imagine that what is repressed exercises a continuous straining in the direction of consciousness, so that the balance has to be kept by means of a steady counter-pressure. A constant expenditure of energy, therefore, is entailed in maintaining a repression, and economically its abrogation denotes a saving. The mobility of

the repression, incidentally, finds expression also in the mental characteristics of the condition of sleep, which alone renders dream-formation possible. With a return to waking life, the repressive cathexes which have been called in are once more put forth.

Finally, we must not forget that after all we have said very little about an instinctual impulse when we state it to be repressed. Without prejudice to the repression, such an impulse may find itself in widely different conditions; it may be inactive, i.e., cathected with only a low degree of mental energy, or its degree of cathexis (and consequently its capacity for activity) may vary. True, its activity will not result in a direct abrogation of the repression, but it will certainly set in motion all the processes which terminate in a breaking through into consciousness by circuitous routes. With unrepressed derivatives of the unconscious, the fate of a particular idea is often decided by the degree of its activity or cathexis. It is an everyday occurrence that such a derivative can remain unrepressed so long as it represents only a small amount of energy, although its content is of such a nature as to give rise to a conflict with conscious control. But the quantitative factor is manifestly decisive for this conflict; as soon as an idea which is fundamentally offensive exceeds a certain degree of strength, the conflict takes on actuality, and it is precisely activation of the idea that leads to its repression. So that, where repression is concerned, an increase in energetic cathexis operates in the same way as an approach to the unconscious, while a decrease in that energy operates like distance from the unconscious or like distortion. We understand that the repressing tendencies can find a substitute for repression in a weakening or lessening of whatever is distasteful to them.

In our discussion hitherto we have dealt with the repression of an instinct-presentation, and by that we understood an idea or group of ideas which is cathected with a definite amount of the mental energy (libido, interest) pertaining to an instinct. Now clinical observation forces us further to dissect something that hitherto we have conceived of as a single entity, for it shows us that beside the idea there is something else, another presentation of the instinct to be considered, and that this other element undergoes a repression which may be quite different from that of the idea. We have adopted the term *charge of affect* for this other element in the mental presentation; it represents that part

of the instinct which has become detached from the idea, and finds proportionate expression, according to its quantity, in processes which become observable to perception as affects. From this point on, in describing a case of repression, we must follow up the fate of the idea which undergoes repression separately from that of the instinctual energy attached to the idea.

We should be glad enough to be able to give some general account of the outcome of both of these, and when we have taken our bearings a little we shall actually be able to do so. In general, repression of the ideational presentation of an instinct can surely only have the effect of causing it to vanish from consciousness, if it had previously been in consciousness, or of holding it back, if it is about to enter it. The difference, after all, is not important; it amounts to much the same thing as the difference between ordering an undesirable guest out of my drawing-room or out of my front hall, and refusing to let him cross my threshold once I have recognized him.<sup>1</sup> The fate of the quantitative factor in the instinct-presentation may be one of three, as we see by a cursory survey of the observations made through psycho-analysis: either the instinct is altogether suppressed, so that no trace of it is found, or it appears in the guise of an affect of a particular qualitative tone, or it is transformed into anxiety. With the two last possibilities we are obliged to focus our attention upon the *transformation* into *affects*, and especially into *anxiety*, of the mental energy belonging to the *instincts*, this being a new possible vicissitude undergone by an instinct.

We recall the fact that the motive and purpose of repression was simply the avoidance of "pain." It follows that the fate of the charge of affect belonging to the presentation is far more important than that of the ideational content of it and is decisive for the opinion we form of the process of repression. If a repression does not succeed in preventing feelings of "pain" or anxiety from arising, we may say that it has failed, even though it may have achieved its aim as far as the ideational element is concerned. Naturally, the case of unsuccessful repression will have more claim on our interest than that of repression which is even-

tually successful; the latter will, for the most part, elude our study.

We now wish to gain some insight into the mechanism of the process of repression, and especially we want to know whether it has a single mechanism only, or more than one, and whether perhaps each of the psychoneuroses may be distinguished by a characteristic repression-mechanism peculiar to itself. At the outset of this inquiry, however, we encounter complications. The mechanism of a repression becomes accessible to us only when we deduce it from its final results. If we confine our observations to the results of its effect on the ideational part of the instinct-presentation, we discover that as a rule repression creates a *substitute-formation*. What, then, is the mechanism of such a substitute-formation, or must we distinguish several mechanisms here also? Further, we know that repression leaves *symptoms* in its train. May we then regard substitute-formation and symptom-formation as coincident processes, and, if this is on the whole possible, does the mechanism of substitute-formation coincide with that of repression? So far as we know at present, it seems probable that the two are widely divergent, that it is not the repression itself which produces substitute-formations and symptoms, but that these latter constitute indications of a *return of the repressed* and owe their existence to quite other processes. It would also seem advisable to examine the mechanisms of substitute- and symptom-formation before those of repression.

Obviously there is no ground here for speculation to explore: on the contrary, the solution of the problem must be found by careful analysis of the results of repression observable in the individual neuroses. I must, however, suggest that we should postpone this task, too, until we have formed reliable conceptions of the relation of consciousness to the unconscious. Only, in order that the present discussion may not be quite unfruitful, I will anticipate by saying: (1) that the mechanism of repression does not in fact coincide with the mechanism or mechanisms of substitute-formation, (2) that there are many different mechanisms of substitute-formation, and (3) that the different mechanisms of repression have at least this one thing in common: a *withdrawal of energetic cathexis* (or of *libido*, if it is a question of sexual instincts).

Further, confining myself to the three best-known forms of psychoneurosis, I will show

<sup>1</sup> This metaphor, applicable to the process of repression, may also be extended to include one of the characteristics of repression mentioned earlier. I need only add that I have to place a sentinel to keep constant guard over the door which I have forbidden this guest to pass, lest he should burst it open (see above).

by means of some examples how the conceptions here introduced find application to the study of repression. From *anxiety-hysteria*, I will choose an instance which has been subjected to thorough analysis—that of an animal-phobia. The instinctual impulse subjected to repression here is a libidinal attitude towards the father, coupled with dread of him. After repression, this impulse vanishes out of consciousness: the father does not appear in consciousness as an object for the libido. As a substitute for him we find in a corresponding situation some animal which is more or less suited to be an object of dread. The substitute-formation of the ideational element has established itself by way of a displacement along the line of a series of associated ideas which is determined in some particular way. The quantitative element has not vanished, but has been transformed into anxiety. The result is a fear of a wolf, instead of a claim for love from the father. Of course the categories here employed are not enough to supply a complete explanation even of the simplest case of psychoneurosis: there are always other points of view to be taken into account.

Such a repression as that which takes place in an animal-phobia must be described as radically unsuccessful. All that it has done is to remove the idea and set another in its place; it has not succeeded at all in its aim of avoiding "pain." On this account, too, the work of the neurosis, far from ceasing, proceeds into a *second movement*, so to speak, which is designed to attain its immediate and more important aim. There follows an attempt at flight, the formation of the *phobia proper*—a number of things have to be *avoided* in order to prevent an outbreak of anxiety. A more particular investigation would enable us to understand the mechanism by which the phobia achieves its aim.

We are led to quite another view of the process of repression when we consider the picture of a true *conversion-hysteria*. Here the salient point is that it is possible to bring about a total disappearance of the charge of affect. The patient then displays towards his symptoms what Charcot called "*la belle indifférence des hystériques*." At other times, this suppression is not so completely successful: a part of the sensation of distress attaches to the symptoms themselves, or it has proved impossible entirely to prevent outbreaks of anxiety, and this in its turn sets the mechanism of phobia-formation working. The ideational content of

the instinct-presentation is completely withdrawn from consciousness; as a substitute-formation—and concurrently, as a symptom—we have an excessive innervation (in typical cases, a somatic innervation), sometimes of a sensory, sometimes of a motor character, either as an excitation or as an inhibition. The area of over-innervation proves on closer observation to belong to the repressed instinct-presentation itself, and, as if by a process of *condensation*, to have absorbed the whole cathexis. Of course, these remarks do not cover the whole mechanism of a conversion-hysteria; the element of *regression* especially, which will be appraised in another connection, has to be taken into account.

In so far as it is rendered possible only by means of extensive substitute-formations, the repression which takes place in hysteria may be pronounced entirely unsuccessful; with reference to mastering the charge of affect however, which is the real task of repression, it generally betokens a complete success. Again, in conversion-hysteria the process of repression terminates with the formation of the symptom and does not, as in anxiety-hysteria, need to proceed to a *second-movement*—or, strictly speaking, an unlimited number of *movements*.

A totally different aspect of repression is shown in the third affection to which we are referring for purposes of this comparison: in the *obsessional neurosis*. Here we are at first in doubt what it is that we have to regard as the repressed instinct-presentation—a libidinal or a hostile trend. This uncertainty arises because the obsessional neurosis rests on the premise of a regression by means of which a sadistic trend has been substituted for a tender one. It is this hostile impulse against a loved person which has undergone repression. The effect at an early phase of the work of repression is quite different from that produced later. At first the repression is completely successful, the ideational content is rejected, and the affect made to disappear. As a substitute-formation, there arises an alteration in the ego, an increased sensitiveness of conscience, which can hardly be called a symptom. Substitute- and symptom-formation do not coincide here. Here, too, we learn something about the mechanism of repression. Repression, as it invariably does, has brought about a withdrawal of libido, but for this purpose it has made use of a *reaction-formation*, by intensifying an antithesis. So here the substitute-formation has the same mechanism as the repression and at bottom

coincides with it, while yet chronologically, as well as in its content, it is distinct from the symptom-formation. It is very probable that the whole process is made possible by the ambivalent relation into which the sadistic impulse destined for repression has been introduced.

But the repression, at first successful, does not hold; in the further course of things its failure becomes increasingly obvious. The ambivalence which has allowed repression to come into being by means of reaction-formation also constitutes the point at which the repressed succeeds in breaking through again. The vanished affect is transformed, without any diminution, into dread of the community, pangs of conscience, or self-reproaches; the rejected idea is replaced by a *displacement-substitute*, often by displacement on to something utterly trivial or indifferent. For the most part, there is an unmistakable tendency to complete re-establishment of the repressed idea. Failure of repression of the quantitative factor brings into play, by means of various taboos and prohibitions, the same mechanism of flight as we have seen at work in the formation of hysterical

phobias. The rejection of the idea from consciousness is, however, obstinately maintained, because it ensures abstention from action, preclusion of the motor expression of an impulse. So the final form of the work of repression in the obsessional neurosis is a sterile and never-ending struggle.

The short series of comparisons which have been presented here may easily convince us that more comprehensive investigations are necessary before we can hope to understand thoroughly the processes connected with repression and the formation of neurotic symptoms. The extraordinary intricacy of all the factors to be taken into consideration leaves us only one way open by which to present them. We must select first one and then another point of view, and follow it up through the material at our disposal, as long as application of it seems to prove fruitful. Each separate point so treated will be incomplete in itself and there cannot fail to be obscurities where we touch upon material not previously dealt with; but we may hope that the final synthesis of them all will lead to a good understanding of the subject.

# The Unconscious<sup>1</sup>

PSYCHO-ANALYSIS has taught us that the essence of the process of repression lies, not in abrogating or annihilating the ideational presentation of an instinct, but in withholding it from becoming conscious. We then say of the idea that it is in a state of *unconsciousness*, of being not apprehended by the conscious mind, and we can produce convincing proofs to show that unconsciously it can also produce effects, even of a kind that finally penetrate to consciousness. Everything that is repressed must remain unconscious, but at the very outset let us state that the repressed does not comprise the whole unconscious. The unconscious has the greater compass: the repressed is a part of the unconscious.

How are we to arrive at a knowledge of the unconscious? It is, of course, only as something conscious that we know anything of it, after it has undergone transformation or translation into something conscious. The possibility of such translation is a matter of everyday experience in psycho-analytic work. In order to achieve this, it is necessary that the person analysed should overcome certain resistances, the very same as those which at some earlier time placed the material in question under repression by rejecting it from consciousness.

## I. Justification for the Conception of the Unconscious

In many quarters our justification is disputed for assuming the existence of an unconscious system in the mind and for employing such an assumption for purposes of scientific work. To this we can reply that our assumption of the existence of the unconscious is *necessary* and *legitimate*, and that we possess manifold *proofs* of the existence of the unconscious. It is necessary because the data of consciousness are exceedingly defective; both in healthy and in sick persons, mental acts are often in process which can be explained only by presupposing other acts, of which consciousness yields no evidence. These include not only the *parapraxes*<sup>2</sup> and dreams of healthy persons, and

everything designated a *mental symptom* or an *obsession* in the sick; our most intimate daily experience introduces us to sudden ideas of the source of which we are ignorant, and to results of mentation arrived at we know not how. All these conscious acts remain disconnected and unintelligible if we are determined to hold fast to the claim that every single mental act performed within us must be consciously experienced; on the other hand, they fall into a demonstrable connection if we interpolate the unconscious acts that we infer. A gain in meaning and connection, however, is a perfectly justifiable motive, one which may well carry us beyond the limitations of direct experience. When, after this, it appears that the assumption of the unconscious helps us to construct a highly successful practical method, by which we are enabled to exert a useful influence upon the course of conscious processes, this success will have won us an incontrovertible proof of the existence of that which we assumed. We become obliged, then, to take up the position that it is both untenable and presumptuous to claim that whatever goes on in the mind must be known to consciousness.

We can go further and in support of an unconscious mental state allege that only a small content is embraced by consciousness at any given moment, so that the greater part of what we call *conscious knowledge* must in any case exist for very considerable periods of time in a condition of latency, that is to say, of unconsciousness, of not being apprehended by the mind. When all our latent memories are taken into consideration, it becomes totally incomprehensible how the existence of the unconscious can be gainsaid. We then encounter the objection that these latent recollections can no longer be described as *mental processes*, but that they correspond to residues of somatic processes from which something mental can once more proceed. The obvious answer to this should be that a latent memory is, on the contrary, indubitably a residuum of a mental process. But it is more important to make clear to our own minds that this objection is based on the identification—not, it is true, explicitly stated, but regarded as axiomatic—of conscious and mental. This identification is either a *petitio*

<sup>1</sup> *Collected Papers*, IV; first published in *Zeitschrift*, Vol. III (1915); reprinted in *Sammlung*, 4th Series.

—TR.

*principii* and begs the question whether all that is mental is also necessarily conscious, or else it is a matter of convention, of nomenclature. In this latter case, it is, of course, no more open to refutation than any other convention. The only question that remains is whether it proves so useful that we must needs adopt it. To this we may reply that the conventional identification of the mental with the conscious is thoroughly unpractical. It breaks up all mental continuity, plunges us into the insoluble difficulties of psychophysical parallelism, is open to the reproach that without any manifest grounds it overestimates the part played by consciousness, and finally it forces us prematurely to retire from the territory of psychological research without being able to offer us any compensation elsewhere.

At any rate, it is clear that the question—whether the latent states of mental life, whose existence is undeniable, are to be conceived of as unconscious mental states or as physical ones—threatens to resolve itself into a war of words. We shall, therefore, be better advised to give prominence to what we know with certainty of the nature of these debatable states. Now, as far as their physical characteristics are concerned, they are totally inaccessible to us: no physiological conception nor chemical process can give us any notion of their nature. On the other hand, we know for certain that they have abundant points of contact with conscious mental processes; on being submitted to a certain method of operation they may be transformed into or replaced by conscious processes, and all the categories which we employ to describe conscious mental acts, such as ideas, purposes, resolutions, and so forth, can be applied to them. Indeed, of many of these latent states we have to assert that the only point in which they differ from states which are conscious is just in the lack of consciousness of them. So we shall not hesitate to treat them as objects of psychological research, and that in the most intimate connection with conscious mental acts.

The stubborn denial of a mental quality to latent mental processes may be accounted for by the circumstance that most of the phenomena in question have not been objects of study outside psycho-analysis. Anyone who is ignorant of the facts of pathology, who regards the blunders of normal persons as accidental, and who is content with the old saw that dreams are froth need only ignore a few more problems of the psychology of consciousness in order to

dispense with the assumption of an unconscious mental activity. As it happens, hypnotic experiments, and especially post-hypnotic suggestion, had demonstrated tangibly, even before the time of psycho-analysis, the existence and mode of operation of the unconscious in the mind.

The assumption of an unconscious is, moreover, in a further respect a perfectly *legitimate* one, inasmuch as in postulating it we do not depart a single step from our customary and accepted mode of thinking. By the medium of consciousness, each one of us becomes aware only of his own states of mind; that another man possesses consciousness is a conclusion drawn by analogy from the utterances and actions we perceive him to make, and it is drawn in order that this behaviour of his may become intelligible to us. (It would probably be psychologically more correct to put it thus: that without any special reflection we impute to everyone else our own constitution and therefore also our consciousness, and that this identification is a necessary condition of understanding in us.) This conclusion—or identification—was formerly extended by the ego to other human beings, to animals, plants, inanimate matter, and to the world at large, and proved useful as long as the correspondence with the individual ego was overwhelmingly great; but it became more untrustworthy in proportion as the gulf between the ego and the non-ego widened. Today, our judgment is already in doubt on the question of consciousness in animals; we refuse to admit it in plants and we relegate to mysticism the assumption of its existence in inanimate matter. But even where the original tendency to identification has withstood criticism—that is, when the non-ego is our fellow-man—the assumption of a consciousness in him rests upon an inference and cannot share the direct certainty we have of our own consciousness.

Now psycho-analysis demands nothing more than that we should apply this method of inference to ourselves also—a proceeding to which, it is true, we are not constitutionally disposed. If we do this, we must say that all the acts and manifestations which I notice in myself and do not know how to link up with the rest of my mental life must be judged as if they belonged to someone else and are to be explained by the mental life ascribed to that person. Further, experience shows that we understand very well how to interpret in others (i.e., how to fit into their mental context) those

same acts which we refuse to acknowledge as mentally conditioned in ourselves. Some special hindrance evidently deflects our investigations from ourselves and interferes with our obtaining true knowledge of ourselves.

Now this method of inference, applied to oneself in spite of inner opposition, does not lead to the discovery of an unconscious, but leads logically to the assumption of another, second consciousness which is united in myself with the consciousness I know. But at this point criticism may fairly make certain comments. In the first place, a consciousness of which its own possessor knows nothing is something very different from that of another person, and it is questionable whether such a consciousness, lacking, as it does, its most important characteristic, is worthy of any further discussion at all. Those who have contested the assumption of an unconscious system in the mind will not be content to accept in its place an unconscious consciousness. Secondly, analysis shows that the individual latent mental processes inferred by us enjoy a high degree of independence, as though each had no connection with another, and knew nothing about any other. We must be prepared, it would appear, to assume the existence not only of a second consciousness in us, but of a third and fourth also, perhaps of an infinite series of states of consciousness, each and all unknown to us and to one another. In the third place—and this is the most weighty argument of all—we have to take into account that analytic investigation reveals some of these latent processes as having characteristics and peculiarities which seem alien to us, or even incredible, and running directly counter to the well known attributes of consciousness. This justifies us in modifying our inference about ourselves and saying that what is proved is not a second consciousness in us, but the existence of certain mental operations lacking in the quality of consciousness. We shall also, moreover, be right in rejecting the term *subconsciousness* as incorrect and misleading. The known cases of *double conscience* (splitting of consciousness) prove nothing against our view. They may most accurately be described as cases of a splitting of the mental activities into two groups, whereby a single consciousness takes up its position alternately with either the one or the other of these groups.

In psycho-analysis there is no choice for us but to declare mental processes to be in themselves unconscious, and to compare the perception of them by consciousness with the per-

ception of the outside world through the sense-organs; we even hope to extract some fresh knowledge from the comparison. The psycho-analytic assumption of unconscious mental activity appears to us, on the one hand, a further development of that primitive animism which caused our own consciousness to be reflected in all around us; and, on the other hand, it seems to be an extension of the corrections begun by Kant in regard to our views on external perception. Just as Kant warned us not to overlook the fact that our perception is subjectively conditioned and must not be regarded as identical with the phenomena perceived but never really discerned, so psycho-analysis bids us not to set conscious perception in the place of the unconscious mental process which is its object. The mental, like the physical, is not necessarily in reality just what it appears to us to be. It is, however, satisfactory to find that the correction of inner perception does not present difficulties so great as that of outer perception—that the inner object is less hard to discern truly than is the outside world.

## II. Different Significance of the Term Unconscious; the Topographical Aspect

Before going any further, let us note the important, though inconvenient, fact that unconsciousness is only one attribute of the mental and by no means suffices to describe its character. There are mental acts of very varying values which yet have in common the characteristic of being unconscious. The unconscious comprises, on the one hand, processes which are merely latent, temporarily unconscious, but which differ in no other respect from conscious ones and, on the other hand, processes such as those which have undergone repression, which if they came into consciousness must stand out in the crudest contrast to the rest of the conscious mind. It would put an end to all misunderstandings if, from now on, in describing the various kinds of mental acts we were to pay no attention to whether they were conscious or unconscious, but, when classifying and correlating them, inquired only to which instincts and aims they were related, how they were composed and to which of the systems in the mind that are superimposed one upon another they belonged. This, however, is for various reasons impracticable, and it follows that we cannot escape the imputation of ambiguity in that we use the words *conscious* and *unconscious* sometimes in a descriptive and sometimes in a systematic sense, in which latter they

signify inclusion in some particular system and possession of certain characteristics. We might still attempt to avoid confusion by employing for the recognized mental systems certain arbitrarily chosen names which have no reference to consciousness. Only we should first have to justify the principles on which we distinguish the systems, and we should not be able to ignore the question of consciousness, seeing that it forms the point of departure for all our investigations. Perhaps we may look for some assistance from the proposal to employ, at any rate in writing, the abbreviation *Cs* for consciousness and the *Ucs* for the unconscious when we are using the two words in the systematic sense.

To deal with the positive aspects, we now assert on the findings of psycho-analysis that a mental act commonly goes through two phases, between which is interposed a kind of testing process (censorship). In the first phase, the mental act is unconscious and belongs to the system *Ucs*; if upon the scrutiny of the censorship it is rejected, it is not allowed to pass into the second phase; it is then said to be *repressed* and must remain unconscious. If, however, it passes this scrutiny, it enters upon the second phase and thenceforth belongs to the second system, which we will call the *Cs*. But the fact that it so belongs does not unequivocally determine its relation to consciousness. It is not yet conscious, but it is certainly *capable of entering consciousness*, according to J. Breuer's expression; that is, it can now, without any special resistance and given certain conditions, become the object of consciousness. In consideration of this capacity to become conscious, we also call the system *Cs* the *preconscious*. If it should turn out that a certain censorship also determines whether the preconscious becomes conscious, we shall discriminate more sharply between the systems *Pcs* and *Cs*. For the present let it suffice us to bear in mind that the system *Pcs* shares the characteristics of the *Cs*, and that the rigorous censorship exercises its office at the point of transition from the *Ucs* to the *Pcs* (or *Cs*).

By accepting the existence of these (two or three) mental systems, psycho-analysis has departed a step further from the descriptive psychology of consciousness and has taken to itself a new problem and a new content. Up till now, it differed from academic (descriptive) psychology mainly by reason of its dynamic conception of mental processes; now we have to add that it professes to consider mental

topography also, and to indicate in respect of any given mental operation within what system or between what systems it runs its course. This attempt, too, has won it the name of *depth-psychology*. We shall hear that it may be further amplified by yet another aspect of the subject.

If we wish to treat seriously the notion of a topography of mental acts, we must direct our interest to a doubt which arises at this point. When a mental act (let us confine ourselves here to an act of ideation) is transferred from the system *Ucs* into the system *Cs* (or *Pcs*), are we to suppose that this transposition involves a fresh registration comparable to a second record of the idea in question, situated, moreover, in a fresh locality in the mind and side by side with which the original unconscious record continues to exist? Or are we rather to believe that the transformation consists in a change in the state of the idea, involving the same material and occurring in the same locality? This question may appear abstruse, but it must be put if we wish to form a more definite conception of mental topography, of the depth-dimension in the mind. It is a difficult one because it goes beyond pure psychology and touches on the relations of the mental apparatus to anatomy. We know that a rough correlation of this sort exists. Research has afforded irrefutable proof that mental activity is bound up with the function of the brain as with that of no other organ. The discovery of the unequal importance of the different parts of the brain and their individual relations to particular parts of the body and to intellectual activities takes us a step further—we do not know how big a step. But every attempt to deduce from these facts a localization of mental processes, every endeavour to think of ideas as stored up in nerve-cells and of excitations as passing along nerve-fibres, has completely miscarried. The same fate would await any doctrine which attempted to recognize, let us say, the anatomical position of the system *Cs*—conscious mental activity—in the cortex and to localize the unconscious processes in the subcortical parts of the brain. Here there is an hiatus which at present cannot be filled, nor is it one of the tasks of psychology to fill it. Our mental topography has for the present nothing to do with anatomy; it is concerned not with anatomical locations, but with regions in the mental apparatus, irrespective of their possible situation in the body.

In this respect, then, our work is untram-

melled and may proceed according to its own requirements. It will, moreover, be useful for us to remind ourselves that our hypotheses can in the first instance lay claim only to the value of illustrations. The former of the two possibilities which we considered—namely, that the conscious phase of an idea implies a fresh record of it, which must be localized elsewhere—is doubtless the cruder but also the more convenient. The second assumption—that of a merely functional change of state—is *a priori* more probable, but it is less plastic, less easy to handle. With the first, or topographical, assumption is bound up that of a topographical separation of the systems *Cs* and *Ucs* and also the possibility that an idea may exist simultaneously in two parts of the mental apparatus—indeed, that if it is not inhibited by the censorship, it regularly advances from the one position to the other, possibly without its first location or record being abandoned. This may seem odd, but it can be supported by observations from psycho-analytic practise.

If we communicate to a patient some idea which he has at one time repressed but which we have discovered in him, our telling him makes at first no change in his mental condition. Above all, it does not remove the repression nor undo its effects, as might perhaps be expected from the fact that the previously unconscious idea has now become conscious. On the contrary, all that we shall achieve at first will be a fresh rejection of the repressed idea. At this point, however, the patient has in actual fact the same idea in two forms in two separate localities in his mental apparatus: first, he has the conscious memory of the auditory impression of the idea conveyed in what we told him, and, secondly and side by side with this, he has—as we know for certain—the unconscious memory of his actual experience existing in him in its earlier form. Now in reality there is no lifting of the repression until the conscious idea, after overcoming the resistances, has united with the unconscious memory-trace. Only through bringing the latter itself into consciousness is the effect achieved. On superficial consideration this would seem to show that conscious and unconscious ideas are different and topographically separated records of the same content. But a moment's reflection shows that the identity of the information given to the patient with his own repressed memory is only apparent. To have listened to something and to have experienced something are psychologically two different things, even

though the content of each be the same.

So, for the moment, we are not able to decide between the two possibilities that we have discussed. Perhaps later on we shall come upon certain factors which may turn the balance in favour of one or the other. Perhaps we shall discover that our question, as we formulated it, was not sufficiently comprehensive and that the difference between a conscious and an unconscious idea has to be defined quite otherwise.

### III. *Unconscious Emotions*

We limited the foregoing discussion to ideas and may now raise a new question, the answer to which must contribute to the elucidation of our theoretical position. We said that there were conscious and unconscious ideas; but are there also unconscious instinctual impulses, emotions, and feelings, or are such constructions in this instance devoid of any meaning?

I am indeed of opinion that the antithesis of conscious and unconscious does not hold for instincts. An instinct can never be an object of consciousness—only the idea that represents the instinct. Even in the unconscious, moreover, it can only be represented by the idea. If the instinct did not attach itself to an idea or manifest itself as an affective state, we could know nothing about it. Though we do speak of an unconscious or a repressed instinctual impulse, this is a looseness of phraseology which is quite harmless. We can only mean an instinctual impulse the ideational presentation of which is unconscious, for nothing else comes into consideration.

We should expect the answer to the question about unconscious feelings, emotions, and affects to be just as easily given. It is surely of the essence of an emotion that we should feel it, i.e., that it should enter consciousness. So for emotions, feelings, and affects to be unconscious would be quite out of the question. But in psycho-analytic practise we are accustomed to speak of unconscious love, hate, anger, etc., and find it impossible to avoid even the strange conjunction, *unconscious consciousness of guilt*, or a paradoxical *unconscious anxiety*. Is there more meaning in the use of these terms than there is in speaking of *unconscious instincts*?

The two cases are really not on all fours. To begin with, it may happen that an affect or an emotion is perceived, but misconstrued. By the repression of its proper presentation, it is forced to become connected with another idea, and is now interpreted by consciousness as the ex-

pression of this other idea. If we restore the true connection, we call the original affect *unconscious*, although the affect was never unconscious, but its ideational presentation had undergone repression. In any event, the use of such terms as *unconscious affect and emotion* has reference to the fate undergone, in consequence of repression, by the quantitative factor in the instinctual impulse.<sup>1</sup> We know that an affect may be subjected to three different vicissitudes: either it remains, wholly or in part, as it is; or it is transformed into a qualitatively different charge of affect, above all into anxiety; or it is suppressed, i.e., its development is hindered altogether. (These possibilities may perhaps be studied even more easily in the technique of the dream-work than in the neuroses.) We know, too, that to suppress the development of affect is the true aim of repression and that its work does not terminate if this aim is not achieved. In every instance where repression has succeeded in inhibiting the development of an affect we apply the term *unconscious* to those affects that are restored when we undo the work of repression. So it cannot be denied that the use of the terms in question is logical; but a comparison of the unconscious affect with the unconscious idea reveals the significant difference that the unconscious idea continues, after repression, as an actual formation in the system *Ucs*, whilst to the unconscious affect there corresponds in the same system only a potential disposition which is prevented from developing further. So that, strictly speaking, although no fault be found with the mode of expression in question, there are no unconscious affects in the sense in which there are unconscious ideas. But there may very well be in the system *Ucs* affect-formations which, like others, come into consciousness. The whole difference arises from the fact that ideas are cathexes—ultimately of memory-traces—whilst affects and emotions correspond with processes of discharge, the final expression of which is perceived as feeling. In the present state of our knowledge of affects and emotions, we cannot express this difference more clearly.

It is of especial interest to us to have established the fact that repression can succeed in inhibiting the transformation of an instinctual impulse into affective expression. This shows us that the system *Cs* normally controls affectivity as well as access to motility; and this enhances the importance of repression, since it shows us that the latter is responsible, not

merely when something is withheld from consciousness, but also when affective development and the inauguration of muscular activity is prevented. Conversely, too, we may say that as long as the system *Cs* controls activity and motility, the mental condition of the person in question may be called *normal*. Nevertheless, there is an unmistakable difference in the relation of the controlling system to the two allied processes of discharge.<sup>2</sup> Whereas the control of the system *Cs* over voluntary motility is firmly rooted, regularly withstands the onslaught of neurosis, and only breaks down in psychosis, the control of the *Cs* over affective development is less firmly established. Even in normal life we can recognize that a constant struggle for primacy over affectivity goes on between the two systems *Cs* and *Pcs*, that certain spheres of influence are marked off one from another, and that the forces at work tend to mingle.

The importance of the system *Cs* (*Pcs*) for the avenues of affective and motor discharge enables us to understand also the rôle which falls to substitutive ideas in determining the form of a disease. It is possible for affective development to proceed directly from the system *Ucs*; in this case it always has the character of anxiety, the substitute for all repressed affects. Often, however, the instinctual impulse has to wait until it has found a substitutive idea in the system *Cs*. Affective development can then proceed from this conscious substitute, the nature of which determines the qualitative character of the affect. We have asserted that, under repression, a severance takes place between the affect and the idea to which it belongs, and that each then fulfils its separate destiny. For purposes of description this is incontrovertible; in actuality, however, the affect does not as a rule arise until it has succeeded in penetrating into the *Cs* in attachment to some new substitutive idea.

#### IV. Topography and Dynamics of Repression

So far we have gathered from our discussion that repression is essentially a process affecting ideas, on the border between the systems *Ucs* and *Pcs* (*Cs*), and we can now make a fresh attempt to describe this process more minutely. It must be a matter of withdrawal of cathexis; but the question is: in what system

<sup>2</sup> Affectivity manifests itself essentially in motor (i.e., secretory and circulatory) discharge resulting in an (internal) alteration of the subject's own body without reference to the outer world; motility, in actions designed to effect changes in the outer world.

<sup>1</sup> Cf. the preceding paper on *Repression*, p. 422.

does the withdrawal take place and to which system does the cathexis withdrawn belong?

In the *Ucs* the repressed idea remains capable of action and must therefore have retained its cathexis. So it must be something else which has been withdrawn. Let us take the case of repression proper (*after-expulsion*), as it affects an idea which is preconscious or even has already entered consciousness. Repression can consist here only in the withdrawal from the idea of the (pre)conscious cathexis which belongs to the system *Pcs*. The idea then remains without cathexis, or receives cathexis from the *Ucs*, or retains the unconscious cathexis which it previously had. We have, therefore, withdrawal of the preconscious, retention of the unconscious, or substitution of an unconscious for a preconscious, cathexis. We notice, moreover, that we have unintentionally, as it were, based these reflections upon the assumption that the transition from the system *Ucs* to the system nearest to it is not effected through the making of a new record but through a change in its state, an alteration in its cathexis. The functional hypothesis has here easily routed the topographical.

But this process of withdrawal of libido does not suffice to make comprehensible to us another characteristic of repression. It is not clear why the idea which has retained its cathexis, or has received cathexis from the *Ucs*, should not, in virtue of its cathexis, renew the attempt to penetrate into the system *Pcs*. The withdrawal of libido would then have to be repeated, and the same performance would recur interminably, but the result would not be repression. In the same way the mechanism just discussed of withdrawal of preconscious cathexis would fail to explain the process of primal repression; for here we have to consider an unconscious idea which as yet has received no cathexis from the *Pcs* and therefore cannot be deprived of it.

What we are looking for, therefore, is another process which maintains the repression in the first case and, in the second, ensures its being established and continued; and this other process we can only find in the assumption of an *anti-cathexis*, by means of which the system *Pcs* guards itself against the intrusion of the unconscious idea. We shall see from clinical examples how such an anti-cathexis established in the system *Pcs* manifests itself. This it is which represents the continuous effort demanded by a primal repression but also guarantees its persistence. The anti-cathexis is the sole mechanism of primal repression; in the case of

repression proper (*after-expulsion*) there is in addition withdrawal of the preconscious cathexis. It is quite possible that the cathexis withdrawn from the idea is the very one used for anti-cathexis.

We see how we have gradually been led to introduce a third point of view into the scheme of mental phenomena—beside the dynamic and the topographical, we take the *economic* standpoint, one from which we try to follow out the fate of given volumes of excitation and to achieve, at least relatively, some assessment of it. It will be only right to give a special name to the way of regarding things which is the final result of psycho-analytic research. I propose that, when we succeed in describing a mental process in all its aspects, dynamic, topographic, and economic, we shall call this a *metapsychological* presentation. We must say beforehand that in the present state of our knowledge we shall succeed in this only at isolated points.

Let us make a tentative effort to give a metapsychological description of the process of repression in the three transference neuroses, which are familiar to us. Here we may substitute for the term *cathexis* that of *libido*, because, as we know, in this case it is the fates of sexual impulses with which we are dealing.

In anxiety-hysteria a preliminary phase of the process is frequently overlooked, perhaps indeed is really omitted; on careful observation, however, it can be clearly discerned. It consists in anxiety appearing without the subject knowing what he is afraid of. We must suppose that there was present in the *Ucs* some love-impulse which demanded to be translated into the system *Pcs*; the preconscious cathexis, however, recoiled from it in the manner of an attempt at flight, and the unconscious libidinal cathexis of the rejected idea was discharged in the form of anxiety. Then, at some repetition of this process, a first step was taken in the direction of mastering this distressing development of anxiety. The fugitive cathexis attached itself to a substitutive idea which, on the one hand, was connected by association with the rejected idea, and, on the other, escaped repression by reason of its remoteness from that idea (displacement-substitute), and which permitted of a rationalization of the still uncontrollable outbreak of anxiety. The substitutive idea now plays the part of an anti-cathexis for the system *Cs* (*Pcs*) by securing that system against an emergence into consciousness of the repressed idea; on the other hand, it is, or acts as if it were, the point

at which the anxiety-affect, which is now all the more uncontrollable, may break out and be discharged. Clinical observation shows, for instance, that when a child suffers from an animal-phobia he experiences anxiety under two kinds of conditions: in the first place, when the repressed love-impulse becomes intensified, and, in the second, when the child perceives the animal it is afraid of. The substitutive idea acts in the one instance as a conductor from the system *Ucs* to the system *Cs*; in the other instance, as an independent source for the release of anxiety. The extending control on the part of the system *Cs* usually manifests itself by a tendency for the substitutive idea to be aroused more easily as time goes on in the second rather than the first way. Perhaps the child ends by behaving as though he had no liking at all for his father but had become quite free from him, and as though the fear of the animal were the real fear. Only that this fear of the animal, fed as such a fear is from the springs of unconscious instinct, proves obdurate and extravagant in the face of all influences brought to bear from the system *Cs*, and thereby betrays its origin in the system *Ucs*.

In the second phase of anxiety-hysteria, therefore, the anti-cathexis from the system *Cs* has led to substitute-formation. Soon the same mechanism is applied in a fresh direction. The process of repression, as we know, is not yet terminated, and finds a further aim in the task of inhibiting the outbreak of anxiety started by the substitute. This happens in the following manner: all the associations in the neighbourhood of the substitutive idea become endowed with a peculiar intensity of cathexis, so that they may display a high degree of sensibility to excitation. Excitation at any point of this protective structure must, on account of its connection with the substitutive idea, give rise to a slight degree of development of anxiety, which is then used as a signal to inhibit, by means of a fresh flight on the part of the cathexis, any further development of anxiety. The further the sensitive and vigilant anti-cathexis becomes extended round the substitute which is feared, the more exactly can the mechanism function which is designed to isolate the substitutive idea and to protect it from fresh excitation. Naturally these precautions guard only against excitations approaching the substitutive idea from without through perception, never against instinctual excitation which encounters the substitutive idea from the direction of its connection with the repressed idea.

So they begin to operate only when the substitute has successfully taken over representation of what has been repressed, and they can never operate with complete security. With each increase of instinctual excitation, the protecting rampart round the substitutive idea must be shifted a little further outwards. The whole construction, which is produced in analogous fashion in the other neuroses, is termed a *phobia*. The avoidances, renunciations, and prohibitions by which we recognize anxiety-hysteria are the manifestations of flight from conscious cathexis of the substitutive idea. Surveying the whole process, we may say that the third phase has repeated and amplified the work of the second. The system *Cs* now protects itself by an anti-cathexis of its surrounding associations against the activation of the substitutive idea, just as previously that system secured itself by cathexis of the substitutive idea against the emergence of the repressed idea. Substitute-formation by the way of displacement has thus proceeded in its course. We must also add that the system *Cs* had formerly only one little point at which the repressed instinctual impulse could break through, namely, the substitutive idea; but that ultimately the whole protective structure of the phobia corresponds to a salient of unconscious influence of this kind. Further, we may lay stress on the interesting point of view that, by the whole defence-mechanism thus set in action, a projection outwards of the menace from the instinct has been achieved. The ego behaves as if the danger of an outbreak of anxiety threatened it not from the direction of an instinct but from the direction of perception: this enables the ego to react against this external danger with the attempts at flight consisting of the avoidances characteristic of a phobia. In this process, repression succeeds in one particular: the discharge of anxiety may be to some extent dammed up, but only at a heavy sacrifice of personal freedom. Attempts at flight from the claims of instinct are, however, in general useless, and the result of the flight by means of a phobia remains still unsatisfactory.

A great deal of what we have recognized as true of anxiety-hysteria holds good for the two other neuroses also, so that we can confine our discussion to the points of difference and the part played by the anti-cathexis. In conversion-hysteria the instinctual cathexis of the repressed idea is transformed into the innervation necessary for the symptom. How far and in what circumstances the unconscious idea discharges

its cathexis through this outlet towards inner-  
vation, so that it can relinquish its pressure  
towards the system *Cs*—these and similar ques-  
tions had better be reserved for a special in-  
vestigation of hysteria. In conversion-hysteria,  
the part played by the anti-cathexis proceeding  
from the system *Cs* (*Pcs*) is clear and becomes  
manifest in the symptom-formation. It is the  
anti-cathexis that decides upon what part of the  
instinct-presentation the whole cathexis may  
be concentrated. The part thus selected to form  
a symptom fulfils the condition of expressing  
the aim of the instinctual impulse no less than  
the defensive or punishing endeavour of the  
system *Cs*; so it achieves hyper-cathexis and is  
maintained from both directions like the sub-  
stitutive idea in anxiety-hysteria. From this  
circumstance we may conclude without much  
more ado that the degree of expenditure in re-  
pression put forth by the system *Cs* need not  
be commensurate with the energetic cathexis of  
the symptom; for the strength of the repression  
is measured by the anti-cathexis put forth, and  
the symptom is supported not only by this anti-  
cathexis, but also by the instinctual cathexis  
from the system *Ucs* which is interwoven  
with it.

With reference to the obsessional neurosis,  
we need only add to the observations brought  
forward in the preceding paper<sup>1</sup> that here the  
anti-cathexis of the system *Cs* comes most no-  
ticeably into the foreground. It is this that  
brings about the first repression, in the shape  
of a reaction-formation, and later it is the point  
at which the repressed idea breaks through. We  
may find room for the supposition that, if the  
work of repression seems far less successful in  
anxiety-hysteria and in the obsessional neurosis  
than in conversion-hysteria, it is because the  
anti-cathexis is so prominent, and all outlet  
is lacking.

#### V. *Special Characteristics of the System Ucs*

The differentiation we have drawn between  
the two systems within the mind receives fresh  
significance when we observe that processes in  
the one system, *Ucs*, show characteristics which  
are not again met with in the system immedi-  
ately above it.

The kernel of the system *Ucs* consists of in-  
stinct-presentations whose aim is to discharge  
their cathexis; that is to say, they are wish-  
impulses. These instinctual impulses are co-  
ordinate with one another, exist independently  
side by side, and are exempt from mutual con-

tradiction. When two wishes whose aims must  
appear to us incompatible become simultane-  
ously active, the two impulses do not detract  
one from the other or cancel each other, but  
combine to form an intermediate aim, a com-  
promise.

There is in this system no negation, no  
dubity, no varying degree of certainty: all  
this is only imported by the work of the cen-  
sorship which exists between the *Ucs* and the  
*Pcs*. Negation is, at a higher level, a substitute  
for repression. In the *Ucs* there are only con-  
tents more or less strongly cathected.

Intensity of cathexis is mobile in a far greater  
degree in this than in the other systems. By  
the process of displacement, one idea may sur-  
render to another the whole volume of its  
cathexis; by that of condensation it may ap-  
propriate the whole cathexis of several other  
ideas. I have proposed to regard these two  
processes as distinguishing marks of the so-  
called *primary process* in the mind. In the sys-  
tem *Pcs* the *secondary process*<sup>2</sup> holds sway;  
where a primary process is allowed to take its  
course in connection with elements belonging  
to the system *Pcs*, it appears comic and excites  
laughter.

The processes of the system *Ucs* are time-  
less; i.e., they are not ordered temporally, are  
not altered by the passage of time, in fact bear  
no relation to time at all. The time-relation also  
is bound up with the work of the system *Cs*.

The processes of the *Ucs* are just as little  
related to reality. They are subject to the  
pleasure-principle; their fate depends only upon  
the degree of their strength and upon their con-  
formity to regulation by pleasure and pain.

Let us sum up: *exemption from mutual con-  
tradiction, primary process* (motility of ca-  
thexis), *timelessness*, and *substitution of psy-  
chic for external reality*—these are the charac-  
teristics which we may expect to find in pro-  
cesses belonging to the system *Ucs*.<sup>3</sup>

Unconscious processes can only be observed  
by us under the conditions of dreaming and of  
neurosis; that is to say, when the processes of  
the higher system *Pcs* revert to an earlier level  
by a certain process of degradation (regres-  
sion). Independently they are unrecognizable,  
indeed cannot exist, for the system *Ucs* is at a  
very early stage overlaid by the system *Pcs*  
which has captured the means of access to con-

<sup>2</sup> Cf. Section VII of *The Interpretation of Dreams*,  
which is based upon ideas developed by J. Breuer in  
*Studien über Hysterie*.

<sup>3</sup> We are reserving for a different context the men-  
tion of another notable privilege of the system *Ucs*.

sciousness and to motility. The means of discharge for the system *Ucs* is by means of physical innervation leading to development of affect, but even this outlet is, as we have seen, contested by the system *Pcs*. Left to itself, the system *Ucs* would not in normal conditions be able to bring about any purposive muscular acts, with the exception of those already organized as reflexes.

In order to grasp the full significance of the characteristics of the system *Ucs* described above, we should have to contrast and compare them with those of the system *Pcs*. But this would take us so far afield that I propose that we should once more call a halt and not undertake the comparison of the two till we can do so in connection with our discussion of the higher system: only the most pressing points of all shall be mentioned at this stage.

The processes of the system *Pcs* display, no matter whether they are already conscious or only capable of becoming conscious, an inhibition of the tendency of cathected ideas towards discharge. When a process moves over from one idea to another, the first retains a part of its cathexis, and only a small part undergoes displacement. Displacement and condensation after the mode of the primary process are excluded or very much restricted. This circumstance caused Breuer to assume the existence of two different stages of cathetic energy in mental life: one in which that energy is tonically *bound*, and the other in which it moves freely and presses towards discharge. I think that this discrimination represents the deepest insight we have gained up to the present into the nature of nervous energy, and I do not see how we are to evade such a conclusion. A metapsychological presentation most urgently calls for further discussion at this point, though perhaps that would still be too daring an undertaking.

Further, it devolves upon the system *Pcs* to make communication possible between the different ideational contents so that they can influence one another, to give them a relation to time, to set up the censorship or censorships, and to establish the institution of *testing reality* and the reality-principle. Conscious memory, too, seems to depend wholly on the *Pcs* and should be clearly distinguished from the memory-traces in which the experiences of the *Ucs* become fixed; it probably corresponds with the making of a special record—a conception which we tried to employ as explaining the relation of conscious to unconscious ideas, but

which we have already discarded. In this connection, also, we shall find the means to put an end to our uncertainty regarding the name of the higher system which at present we vaguely call sometimes the *Pcs* and sometimes the *Cs*.

Here, too, it will be as well to utter a warning against over-hasty generalizations about what we have brought to light in regard to apportioning the various mental activities to one or other of the two systems. We are describing the state of affairs as it appears in the adult human being, in whom the system *Ucs* in the strict sense functions only as a stage preliminary to the higher organization. The content and connections of this system as the individual develops, the significance it possesses in the case of animals—these are points on which no conclusion can be deduced from our description: they must be investigated independently. Moreover, in the human being we must be prepared to find possible pathological conditions under which the two systems alter, or even exchange, both their content and their characteristics.

## VI. *Communication between the Two Systems*

It would certainly be wrong to imagine that the *Ucs* remains at rest while the whole work of the mind is performed by the *Pcs*, that the *Ucs* is something finished with, a vestigial organ, a residuum from the process of evolution; wrong also to assume that communication between the two systems is confined to the act of repression, the *Pcs* casting everything which disturbs it into the abyss of the *Ucs*. On the contrary, the *Ucs* is living and capable of development and maintains a number of other relations to the *Pcs*, amongst them that of co-operation. To sum up, we must say that the *Ucs* is continued into its so-called *derivatives*, is accessible to the influence of life, perpetually acts upon the *Pcs*, and even is, on its part, capable of influence by the latter system.

Study of the derivatives of the *Ucs* will altogether disappoint our expectations of a schematically clear division of the one mental system from the other. This circumstance will certainly give rise to dissatisfaction with our results and will probably be used to cast doubts upon the value of our way of distinguishing the two groups of mental processes. Our answer is, however, that we have no other aim but that of translating into theory the results of observation, and we shall deny that there is any obligation on us to achieve, at our very first attempt, a theory that commends itself by its

simplicity, in which all is plain sailing. We defend its complexities so long as we find that they fit in with the results of observation, and we do not abandon our expectation of being guided in the end by those very complexities to recognition of a state of affairs that is at once simple in itself and at the same time answers to all the complications of reality.

Amongst the derivatives of the unconscious instinctual impulses, the character of which we have just described, there are some which unite in themselves opposite features. On the one hand, they are highly organized, exempt from self-contradictoriness, have made use of every acquisition of the system *Cs*, and would hardly be distinguished by our ordinary judgment from the formations of that system. On the other hand, they are unconscious and are incapable of becoming conscious. Thus they belong according to their qualities to the system *Pcs*, but in actual fact to the *Ucs*. Their origin remains decisive for the fate they will undergo. We may compare them with those human half-breeds who, taken all round, resemble white men, but betray their coloured descent by some striking feature or other, on account of which they are excluded from society and enjoy none of the privileges of white people. Of such a nature are the *phantasy-formations* of normal persons as well as of neurotics, which we have recognized as preliminary phases in the formation both of dreams and of symptoms, and which, in spite of their high degree of organization, remain repressed and therefore cannot become conscious. They draw near to consciousness and remain undisturbed so long as they do not become strongly cathected, but as soon as a certain degree of this is exceeded, they are thrust back. Substitute-formations are similar, more highly organized derivatives of the *Ucs*; but these succeed in breaking through into consciousness, thanks to some favourable relation, as, for example, when they coincide with a preconscious anti-cathexis.

When, on another occasion, we examine more closely the way in which entry into consciousness is conditioned, we shall be able to find a solution for some of the difficulties arising here. At this point, it seems a good plan to contrast with the foregoing points of view, which take their rise in consideration of the *Ucs*, one which presents itself from the direction of consciousness. Consciousness regards the whole sum of mental processes as belonging to the realm of the preconscious. A very great part of this preconscious material originates in the un-

conscious, has the characteristics of derivatives of the unconscious, and is subject to a censorship before it can pass into consciousness. Another part of the *Pcs* can become conscious without any censorship. Here we light upon a contradiction of an earlier assumption: from the point of view of repression, we were obliged to place the censorship which is decisive for consciousness between the systems *Ucs* and *Pcs*. Now it becomes probable to us that there is a censorship between the *Pcs* and the *Cs*. But we shall do well not to regard this complication as a difficulty, but to assume that to every transition from one system to that immediately above it (that is, every advance to a higher stage of mental organization) there corresponds a new censorship. As a corollary, we shall have, it is true, to discard the assumption of a continuous laying down of new records.

The reason for all these difficulties is that consciousness, the only characteristic of mental processes directly available to us, is in no wise suited to serve as a criterion for the erection of systems. Apart from the circumstance that what belongs to consciousness is not always in consciousness but can also be temporarily latent, observation has shown that much which shares the attributes of the system *Pcs* does not become conscious; and, further, we shall find that the entry into consciousness is circumscribed by certain dispositions of attention. Hence consciousness stands in no simple relation either to the different systems or to the process of repression. The truth is that it is not only what is repressed that remains alien to consciousness, but also some of the impulses which dominate our ego and which therefore form the strongest functional antithesis to what is repressed. In proportion as we try to win our way to a metapsychological view of mental life, we must learn to emancipate ourselves from our sense of the importance of that symptom which consists in *being conscious*.

So long as we still cling to this, we see our generalizations regularly invaded by exceptions. We see that derivatives of the *Pcs* enter consciousness as substitute-formations and as symptoms, generally after undergoing great distortion in contrast to the *Ucs*, although often many characteristics inviting repression have been retained. We find that many preconscious formations remain unconscious, though, to judge by their nature, we should suppose that they might very well become conscious. Probably in their case the stronger attraction of

the *Ucs* asserts itself. We are led to look for the more important difference, not between the conscious and the preconscious, but between the preconscious and the unconscious. On the border of the *Pcs*, the censorship thrusts back the *Ucs*, but its derivatives can circumvent this censorship, achieve a high degree of organization, and in the *Pcs* reach a certain intensity of cathexis; when, however, this is exceeded, and they try to force themselves into consciousness, they are recognized as derivatives of the *Ucs*, and are repressed afresh at the new frontier by the censorship between the *Cs* and the *Pcs*. Thus the former censorship is exercised against the *Ucs* itself, and the latter against its preconscious derivatives. We might suppose that in the course of individual development the censorship had been advanced a step.

In psycho-analytic treatment the existence of the second censorship, located between the systems *Pcs* and *Cs*, is proved beyond question. We require the patient to produce freely derivatives of the *Ucs*, we pledge him to overcome the objections of the censorship against these preconscious formations becoming conscious, and, by overthrowing this censorship, we open up the way to abrogating the repression accomplished by the earlier one. To this let us add that the existence of the censorship between the *Pcs* and the *Cs* teaches us that becoming conscious is no mere act of perception, but is probably also a *hyper-cathexis*, a further advance in the mental organization.

Let us turn our attention to the communications existing between the unconscious and the other systems, not so much with a view to establishing any fresh fact as in order to avoid omitting the most prominent features. At the roots of instinctual activity, the systems communicate with one another in the freest possible way: some of the processes here set in motion pass through the *Ucs*, as through a preparatory stage, and reach the highest mental development in the *Cs*, whilst some are retained as the *Ucs*. But the *Ucs* is also affected by experiences originating in outer perception. Normally all the paths from perception to the *Ucs* remain open; only those leading out from the *Ucs* are barred by repression.

It is very remarkable that the *Ucs* of one human being can react upon that of another, without the *Cs* being implicated at all. This deserves closer investigation, especially with a view to finding out whether preconscious activity can be excluded as a factor in bringing

this about; but for purposes of description the fact is incontestable.

The content of the system *Pcs* (or *Cs*) is derived partly from the instinctual life (through the medium of the *Ucs*), and partly from perception. It is doubtful how far the processes of this system can exert a direct influence on the *Ucs*; examination of pathological cases often reveals an almost incredible independence and lack of susceptibility to influence on the part of the *Ucs*. A complete divergence of their tendencies, a total dissociation of the two systems, is a general characteristic of disease. Yet psycho-analytic treatment is based upon influence by the *Cs* on the *Ucs*, and shows at any rate that, though laborious, this is not impossible. The derivatives of the *Ucs* which act as intermediaries between the two systems open the way, as we have already said, towards accomplishing this. But we may well suppose that a spontaneously effected alteration in the *Ucs* from the side of the *Cs* is a difficult and slow process.

Co-operation between a preconscious and an unconscious impulse, even when the latter is subject to very strong repression, may be established, if the situation permits of the unconscious impulse operating in harmony with one of the controlling tendencies. The repression is removed for the occasion, the repressed activity being admitted as a reinforcement of the one intended by the ego. In respect of this single constellation, the unconscious becomes ego-syntonic, falls into line with the ego, without any change taking place in the repression otherwise. The effect of the *Ucs* in this co-operation is unmistakable; the reinforced tendencies reveal themselves as, in spite of all, different from the normal—they make possible achievements of special perfection, and they manifest a resistance in the face of opposition similar to that of obsessional symptoms.

The content of the *Ucs* may be compared with a primitive population in the mental kingdom. If inherited mental formations exist in the human being—something analogous to instinct in animals—these constitute the nucleus of the *Ucs*. Later there is added all that is discarded as useless during childhood development, and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems, as a rule, takes place only at puberty.

## VII. Recognition of the Unconscious

So long as we derive our ideas of the *Ucs* only from our knowledge of dream-life and the

transference neuroses, all that we can predicate of that system is probably represented in the foregoing remarks. It is certainly not much, and at some points it gives an impression of obscurity and confusion; especially do we look in vain for the possibility of bringing the *Ucs* into any connection, or classifying it under any heading, with which we are already familiar. Analysis of one of those affections called *narcissistic psychoneuroses* alone promises to furnish us with conceptions through which the enigmatic *Ucs* will be brought within our reach in a tangible fashion.

Since the publication of a work by Abraham (1908)—attributed by its conscientious author to my instigation—we have been trying to define Kraepelin's dementia praecox (Bleuler's schizophrenia) on the basis of its relation to that pair of opposites consisting of the ego and its object. In the transference neuroses (anxiety- and conversion-hysteria and the obsessional neurosis) there was nothing to give special prominence to these opposites. We knew, indeed, that frustration from the side of the object occasioned the outbreak of neurosis and that neurosis involved abandonment of the real object; also that the libido withdrawn from the real object reverted first to an object in phantasy and then to one that had been repressed (introversion). But object-cathexis in general is in such cases retained with great energy, and more minute examination of the processes of repression has forced us to assume that object-cathexis persists in the system *Ucs* in spite of—or rather in consequence of—the repression. Indeed the capacity for transference, of which we make use for therapeutic purposes in these affections, presupposes unimpaired object-cathexis.

In schizophrenia, on the other hand, we have been obliged to assume that after the process of repression the withdrawn libido does not seek a new object, but retreats into the ego; that is to say, that here the object-cathexes are given up, and a primitive objectless condition of narcissism is re-established. The incapacity of these patients for transference—so far as the process of disease extends—their consequent inaccessibility to therapeutic efforts, the repudiation of the outer world characteristic of them, the manifestations of hyper-cathexis of their ego, the final outcome in complete apathy—all these clinical features seem to accord excellently with the assumption that object-cathexes are relinquished. As regards the relation of the two psychical systems to each

other, all observers have been struck by the fact that in schizophrenia a great deal is consciously expressed which in the transference neuroses can be demonstrated to exist in the *Ucs* only by means of psycho-analysis. But at the beginning we were not able to establish any intelligible connection between the ego-object relation and the relationships of consciousness.

In the following unexpected way, we seem to arrive at what we are seeking. In schizophrenics we observe—especially in the earlier stages which are so instructive—a number of changes in *speech*, some of which deserve to be regarded from a particular point of view. The patient often devotes peculiar care to his way of expressing himself, which becomes "precious" and "elaborate." The construction of the sentences undergoes a peculiar disorganization, making them so incomprehensible to us that the patient's remarks seem nonsensical. Often some relation to bodily organs or innervations is prominent in the content of these utterances. This may be correlated with another observation, namely, that, in such symptoms of schizophrenia as are comparable with the substitute-formations of hysteria or the obsessional neurosis, the relation between the substitute and the repressed material nevertheless displays peculiarities which would surprise us in these two forms of neurosis.

Dr. Viktor Tausk of Vienna has placed at my disposal some observations that he has made in the initial stages of schizophrenia, which are particularly valuable in that the patient herself was anxious to explain her utterances further. I will take two of his examples to illustrate the thesis I wish to defend, and I have no doubt that every observer could easily produce plenty of such material.

One of Tausk's patients, a girl who was brought to the clinic after a quarrel with her lover, complained that *her eyes were not right, they were twisted*. This she herself explained by uttering in properly constructed sentences a series of reproaches against her lover. "She could not understand him at all, he looked different every time; he was a shammer, an eye-twister,<sup>1</sup> he had twisted her eyes; now they were not her eyes any more; now she saw the world with different eyes."

The patient's remarks about her first incomprehensible utterance have the value of an analysis, for they contain the equivalent of the original words expressed in a generally com-

<sup>1</sup> *Augenverdreher*, used in German to mean a deceiver.—Tr.

prehensible form; at the same time, they explain the meaning and the genesis of speech-formation in schizophrenia. In agreement with Tausk, I would here lay stress on the point that the relation to the bodily organ (the eye) has usurped the place of the whole content of the thought. The schizophrenic speech displays a hypochondriac trait: it has become *organ-speech*.

A second remark of the same patient's runs: "She was standing in church, suddenly she felt a jerk, she had to *change her position*, as though somebody put her into a position, as though she were *placed in a certain position*."

There follows the analysis by means of a fresh series of reproaches against her lover: "he was common, he had made her common, too, though she was naturally refined; he had made her like himself by leading her to think that he was superior to her; now she had become like him, because she thought she would be better if she were like him; he had *given a false impression of his own position*;<sup>1</sup> now she was just like him (identification!), he had *changed her position*."<sup>2</sup>

The movement by which she *changed her position*, Tausk remarks, stood for the idea of *misrepresenting her position* and for the identification with the lover. Again I would call attention to the manner in which the whole train of thought is dominated by that element which has for its content a bodily innervation (or, rather, the sensation of it). An hysteric would, in the first case, have convulsively rolled her eyes, and, in the second, have given actual jerks, instead of having the impulse to jerk or the sensation of being jerked; and in neither case would this have been accompanied by any conscious thoughts, nor would she afterwards have been able to express any such thoughts.

So far these two observations illustrate what we have called hypochondriac language or *organ-speech*. But they also point to something which seems to us more important, namely, to another state of things of which we have innumerable instances (for example, in the cases quoted in Bleuler's monograph) and which may be reduced to a definite formula. In schizophrenia, *words* are subject to the same process as that which makes dream-images out of dream-thoughts, the one we have called the primary mental process. They undergo conden-

sation, and, by means of displacement, transfer their cathexes to one another without remainder; the process may extend so far that a single word, which on account of its manifold relations is especially suitable, can come to represent a whole train of thought. The works of Bleuler, Jung, and their pupils have yielded abundant material precisely in support of this very proposition.<sup>3</sup>

Before we draw any conclusion from impressions such as these, let us consider further the distinctions between the substitutive idea in schizophrenia and in hysteria and the obsessional neurosis—nice distinctions, it is true, yet producing a very strange effect. A patient whom I have at present under observation has let himself withdraw from all the interests of life on account of the unhealthy condition of the skin of his face. He declares that he has blackheads and that there are deep holes in his face which everyone notices. Analysis shows that he is working out his castration complex upon his skin. At first he busied himself with these blackheads without any misgivings; and it gave him great pleasure to squeeze them out, because, as he said, something spurted out when he did so. Then he began to think that there was a deep cavity wherever he had got rid of a blackhead and he reproached himself most vehemently with having ruined his skin forever by "constantly fiddling at it with his hand." Pressing out the content of the blackheads is clearly to him a substitute for onanism. The cavity which then appears in consequence of his guilty act is the female genital, i.e., stands for the fulfilment of the threat of castration (or the phantasy representing it) called forth by onanism. This substitute-formation has, in spite of its hypochondriacal character, considerable resemblance to an hysterical conversion; and yet we have the feeling that there must be something different in it, that we cannot believe such a substitute-formation possible in a case of hysteria, even before we can say in what the difference consists. A tiny little hole such as a pore of the skin will hardly be used by an hysteric as a symbol for the vagina, which otherwise he will compare with every imaginable object capable of enclosing a space. Besides, we should think that the multiplicity of these little cavities would prevent him from using them as a substitute for the female genital. The same applies to the case of a young patient re-

<sup>1</sup> *Sich vorstellen*=to feign, disguise oneself.—TR.

<sup>2</sup> *Verstellen*=to change the place of. As with *Augen-verdreher*, there is again a play on words, the concrete meaning of the word replacing its metaphorical sense.—TR.

<sup>3</sup> The dream-work, too, occasionally treats words like things, and then creates very similar *schizophrenic* utterances or neologisms.

ported by Tausk some years ago to the Vienna Psycho-Analytical Society. This patient behaved in other respects exactly as though suffering from an obsessional neurosis; he took hours to dress, and so on. The striking feature of the case, however, was that he was able to tell the meaning of his inhibitions without any resistance. For example, in pulling on his stockings he was disturbed by the idea that he must draw apart the knitted stitches, i.e., the holes, and every hole was for him a symbol of the female genital aperture. This again is a thing with which we cannot credit a patient suffering from obsessional neurosis; a patient of this kind observed by R. Reitler (one who suffered from the same lingering over putting on his stockings), after overcoming the resistances, found the explanation that his foot symbolised the penis, putting on the stocking stood for an onanistic act, and that he had constantly to pull the stocking off and on, partly in order to complete the representation of onanism, and partly in order to undo the act.

If we ask ourselves what it is that gives the character of strangeness to the substitute-formation and the symptom in schizophrenia, we come at last to understand that it is the predominance of the word-relation over that of the thing. There is only a very slight similarity between the squeezing out of a blackhead and an ejaculation from the penis, still less similarity between the countless little pores of the skin and the vagina; but in the former case there *is*, in both instances, a spurting out, while in the latter the cynical saying, "a hole is a hole," is *literally* true. The identity of the two when expressed in *words*, not the resemblance of the objects designated, has dictated the substitution. Where the two—word and thing—do not coincide, the substitute-formation in schizophrenia deviates from that in the transference neuroses.

Let us bring these considerations into connection with the conclusion that in schizophrenia the object-cathexes are relinquished. We must then modify this assumption and say: The cathexis of the ideas of the words corresponding to the objects is retained. What we could permissibly call the *conscious idea* of the object can now be split up into the *idea of the word* (verbal idea) and the *idea of the thing* (concrete idea); the latter consists in the cathexis, if not of the direct memory-images of the thing, at least of remoter memory-traces derived from these. It strikes us all at once that now we know what is the difference between a

conscious and an unconscious idea. The two are not, as we supposed, different records of the same content situated in different parts of the mind, nor yet different functional states of cathexis in the same part; but the conscious idea comprises the concrete idea plus the verbal idea corresponding to it, whilst the unconscious idea is that of the thing alone. The system *Ucs* contains the thing-cathexes of the objects, the first and true object-cathexes; the system *Pcs* originates in a hyper-cathexis of this concrete idea by a linking up of it with the verbal ideas of the words corresponding to it. It is such hyper-cathexes, we may suppose, that bring about higher organization in the mind and make it possible for the primary process to be succeeded by the secondary process which dominates *Pcs*. Now, too, we are in a position to state precisely what it is that repression denies to the rejected idea in the transference neuroses—namely, translation of the idea into words which are to remain attached to the object. The idea which is not put into words, or the mental act which has not received hyper-cathexis, then remains in the unconscious in a state of repression.

I may call attention to the fact that already very early we possessed the insight which today enables us to understand one of the most striking characteristics of schizophrenia. The last pages of *The Interpretation of Dreams*, published in 1900, expound the thesis that thought-processes, i.e., those cathected mental acts which are more remote from perception, are in themselves devoid of quality and are unconscious, deriving their capacity to enter consciousness only from association with the residues of word-perceptions. The verbal ideas, for their part, are derived from sense-perceptions in the same way as concrete ideas are; so that the question might be raised why ideas of objects cannot become conscious through the agency of their own residues of perceptions. But possibly thought proceeds in systems that are so far remote from the original residues of perception that they have no longer retained anything of the qualities of these residues, so that in order to become conscious the content of the thought-systems needs to be reinforced by new qualities. Besides, linking them up with words may impart quality even to cathexes to which, representing as they do only relations between the ideas of objects, no quality could accrue from the perceptions themselves. Such relations, comprehensible only through words, form one of the most important parts of our

thought-processes. We understand that linking them up with verbal ideas is still not identical with actually becoming conscious, but only with the potentiality of this; it is therefore characteristic of the system *Pcs* and of that only. Now, however, we note that with these discussions we have departed from our real theme and find ourselves in the midst of problems concerning the preconscious and the conscious, which for good reasons we are reserving for separate treatment.

In considering schizophrenia, which, to be sure, we only touch on here so far as seems indispensable for general knowledge of the *Ucs*, the doubt must occur to us whether the process here termed *repression* has anything at all in common with the repression which takes place in the transference neuroses. The formula that repression is a process which occurs between the systems *Ucs* and *Pcs* (or *Cs*), and results in withholding the repressed material from consciousness, must in any event be modified, in order to embrace the case of dementia praecox and other narcissistic affections. But the ego's attempt at flight, expressing itself in withdrawal of conscious cathexis, nevertheless remains a common factor. The most superficial reflection shows us how much more radically and thoroughly this attempt at flight, this flight of the ego, is carried out in the narcissistic neuroses.

If, in schizophrenia, this flight consists in withdrawal of instinctual cathexis from those points which represent the unconscious idea of the object, it may seem strange that that part of the same idea which belongs to the system *Pcs*—the verbal ideas corresponding to it—should, on the contrary, undergo a more intense cathexis. We might rather expect that the verbal idea, being the preconscious part, would have to sustain the first impact of the repression, and that it would be wholly insusceptible

of cathexis after the repression had proceeded as far as the unconscious concrete ideas. This is certainly difficult to understand. The solution suggests itself that the cathexis of the verbal idea is not part of the act of repression, but represents the first of the attempts at recovery or cure which so conspicuously dominate the clinical picture of schizophrenia. These endeavours are directed towards regaining the lost objects, and it may well be that to achieve this purpose their path to the object must be by way of the word belonging to it; they then have, however, to content themselves with words in the place of things. Our mental activity moves, generally speaking, in one of two opposite directions: either it starts from the instincts and passes through the system *Ucs* to conscious mentation, or, on excitation from without, it passes through the systems *Cs* and *Pcs* till it reaches the unconscious cathexes of the ego and of its objects. This second way must, in spite of the repression which has taken place, have remained clear, and for some distance there is nothing to block the endeavours of the neurosis to regain its objects. When we think in abstractions, there is a danger that we may neglect the relations of words to unconscious concrete ideas, and it must be confessed that the expression and content of our philosophizing begins to acquire an unwelcome resemblance to the schizophrenic's way of thinking. We may, on the other hand, attempt a characterization of the schizophrenic's mode of thought by saying that he treats concrete things as though they were abstract.

If we have really recognized the nature of the *Ucs* and have correctly defined the difference between an unconscious and a preconscious idea, then researches starting from many other points may be expected to bring us back to the same conclusions.

A General Introduction to  
Psycho-Analysis

# A General Introduction to Psycho-Analysis

## PART I

### FIRST LECTURE

#### INTRODUCTION

I do not know what knowledge any of you may already have of psycho-analysis, either from reading or from hearsay. But having regard to the title of my lectures—*Introductory Lectures on Psycho-Analysis*—I am bound to proceed as though you knew nothing of the subject and needed instruction, even in its first elements.

One thing, at least, I may pre-suppose that you know—namely, that psycho-analysis is a method of medical treatment for those suffering from nervous disorders; and I can give you at once an illustration of the way in which psycho-analytic procedure differs from, and often reverses, what is customary in other branches of medicine. Usually, when we introduce a patient to a new form of treatment we minimize its difficulties and give him confident assurances of its success. This is, in my opinion, perfectly justifiable, for we thereby increase the probability of success. But when we undertake to treat a neurotic psycho-analytically we proceed otherwise. We explain to him the difficulties of the method, its long duration, the trials and sacrifices which will be required of him; and, as to the result, we tell him that we can make no definite promises, that success depends upon his endeavours, upon his understanding, his adaptability and his perseverance. We have, of course, good reasons, into which you will perhaps gain some insight later on, for adopting this apparently perverse attitude.

Now forgive me if I begin by treating you in the same way as I do my neurotic patients, for I shall positively advise you against coming to hear me a second time. And with this intention I shall explain to you how of necessity you can

obtain from me only an incomplete knowledge of psycho-analysis and also what difficulties stand in the way of your forming an independent judgment on the subject. For I shall show you how the whole trend of your training and your accustomed modes of thought must inevitably have made you hostile to psycho-analysis, and also how much you would have to overcome in your own minds in order to master this instinctive opposition. I naturally, cannot foretell what degree of understanding of psycho-analysis you may gain from my lectures, but I can at least assure you that by attending them you will not have learnt how to conduct a psycho-analytic investigation, nor how to carry out a psycho-analytic treatment. And further, if any one of you should feel dissatisfied with a merely cursory acquaintance with psycho-analysis and should wish to form a permanent connection with it, I shall not merely discourage him, but I shall actually warn him against it. For, as things are at the present time, not only would the choice of such a career put an end to all chances of academic success, but, upon taking up work as a practitioner, such a man would find himself in a community which misunderstood his aims and intentions, regarded him with suspicion and hostility, and let loose upon him all the latent evil impulses harboured within it. Perhaps you can infer from the accompaniments of the war now raging in Europe what a countless host that is to reckon with.

However, there are always some people to whom the possibility of a new addition to knowledge will prove an attraction strong enough to survive all such inconveniences. If there are any such among you who will appear at my second lecture in spite of my words of warning they will be welcome. But all of you have a right to know what these inherent difficulties of psycho-analysis are to which I have alluded.

First of all, there is the problem of the teach-

NOTE: A series of lectures delivered at the Vienna Psychiatric Clinic, the first fifteen in 1915-16, the next thirteen in 1916-17, first published in German in 1917; edition here used translated by Joan Riviere for the 2nd English edition published in London in 1922. (First English edition had appeared in 1920.)

ing and exposition of the subject. In your medical studies you have been accustomed to use your eyes. You see the anatomical specimen, the precipitate of the chemical reaction, the contraction of the muscle as the result of the stimulation of its nerves. Later, you come into contact with the patients; you learn the symptoms of disease by the evidence of your senses; the results of pathological processes can be demonstrated to you, and in many cases even the exciting cause of them in an isolated form. On the surgical side, you are witnesses of the measures by which the patient is helped, and are permitted to attempt them yourselves. Even in psychiatry, demonstration of patients, of their altered expression, speech and behaviour, yields a series of observations which leave a deep impression on your minds. Thus a teacher of medicine acts for the most part as an exponent and guide, leading you as it were through a museum, while you gain in this way a direct relationship to what is displayed to you and believe yourselves to have been convinced by your own experience of the existence of the new facts.

But in psycho-analysis, unfortunately, all this is different. In psycho-analytic treatment nothing happens but an exchange of words between the patient and the physician. The patient talks, tells of his past experiences and present impressions, complains, and expresses his wishes and his emotions. The physician listens, attempts to direct the patient's thought-processes, reminds him, forces his attention in certain directions, gives him explanations and observes the reactions of understanding or denial thus evoked. The patient's unenlightened relatives—people of a kind to be impressed only by something visible and tangible, preferably by the sort of *action* that may be seen at a cinema—never omit to express their doubts of how "mere talk can possibly cure anybody." Their reasoning is of course as illogical as it is inconsistent. For they are the same people who are always convinced that the sufferings of neurotics are purely "in their own imagination." Words and magic were in the beginning one and the same thing, and even today words retain much of their magical power. By words one of us can give to another the greatest happiness or bring about utter despair; by words the teacher imparts his knowledge to the student; by words the orator sweeps his audience with him and determines its judgments and decisions. Words call forth emotions and are universally the means by which we influence our fellow-creatures. Therefore let us not despise the use of

words in psycho-therapy and let us be content if we may overhear the words which pass between the analyst and the patient.

But even that is impossible. The dialogue which constitutes the analysis will admit of no audience; the process cannot be demonstrated. One could, of course, exhibit a neurasthenic or hysterical patient to students at a psychiatric lecture. He would relate his case and his symptoms, but nothing more. He will make the communications necessary to the analysis only under the conditions of a special affective relationship to the physician; in the presence of a single person to whom he was indifferent he would become mute. For these communications relate to all his most private thoughts and feelings, all that which as a socially independent person he must hide from others, all that which, being foreign to his own conception of himself, he tries to conceal even from himself.

It is impossible, therefore, for you to be actually present during a psycho-analytic treatment; you can only be told about it, and can learn psycho-analysis, in the strictest sense of the word, only by hearsay. This tuition at second hand, so to say, puts you in a very unusual and difficult position as regards forming your own judgment on the subject, which will therefore largely depend on the reliance you can place on your informant.

Now imagine for a moment that you were present at a lecture in history instead of in psychiatry, and that the lecturer was dealing with the life and conquests of Alexander the Great. What reason would you have to believe what he told you? The situation would appear at first sight even more unsatisfactory than in the case of psycho-analysis, for the professor of history had no more part in Alexander's campaigns than you yourselves; the psycho-analyst at least informs you of matters in which he himself has played a part. But then we come to the question of what evidence there is to support the historian. He can refer you to the accounts of early writers who were either contemporaries or who lived not long after the events in question, such as Diodorus, Plutarch, Arrian, and others; he can lay before you reproductions of the preserved coins and statues of the king, and pass round a photograph of the mosaic at Pompeii representing the battle at Issus. Yet, strictly speaking, all these documents only prove that the existence of Alexander and the reality of his deeds were already believed in by former generations of men, and your criticism might begin anew at this point.

And then you would find that not everything reported of Alexander is worthy of belief or sufficiently authenticated in detail, but I can hardly suppose that you would leave the lecture-room in doubt altogether as to the reality of Alexander the Great. Your conclusions would be principally determined by two considerations: first, that the lecturer could have no conceivable motive for attempting to persuade you of something which he did not himself believe to be true, and secondly, that all the available authorities agree more or less in their accounts of the facts. In questioning the accuracy of the early writers you would apply these tests again, the possible motives of the authors and the agreement to be found between them. The result of such tests would certainly be convincing in the case of Alexander, probably less so in regard to figures like Moses and Nimrod. Later on you will perceive clearly enough what doubts can be raised against the credibility of an exponent of psycho-analysis.

Now you will have a right to ask the question: "If no objective evidence for psycho-analysis exists and no possibility of demonstrating the process, how is it possible to study it at all or to convince oneself of its truth?" The study of it is indeed not an easy matter, nor are there many people who have thoroughly learned it; still, there is, of course, some way of learning it. Psycho-analysis is learnt first of all on oneself, through the study of one's own personality. This is not exactly what is meant by *introspection*, but it may be so described for want of a better word. There is a whole series of very common and well-known mental phenomena which can be taken as material for self-analysis when one has acquired some knowledge of the method. In this way one may obtain the required conviction of the reality of the processes which psycho-analysis describes, and of the truth of its conceptions, although progress on these lines is not without its limitations. One gets much further by submitting oneself to analysis by a skilled analyst, undergoing the working of the analysis in one's own person and using the opportunity to observe the finer details of the technique which the analyst employs. This, eminently the best way, is of course only practicable for individuals and cannot be used in a class of students.

The second difficulty you will find in connection with psycho-analysis is not, on the other hand, inherent in it, but is one for which I must hold you yourselves responsible, at least in so far as your medical studies have influenced

you. Your training will have induced in you an attitude of mind very far removed from the psycho-analytical one. You have been trained to establish the functions and disturbances of the organism on an anatomical basis, to explain them in terms of chemistry and physics, and to regard them from a biological point of view; but no part of your interest has ever been directed to the mental aspects of life, in which, after all, the development of the marvellously complicated organism culminates. For this reason a psychological attitude of mind is still foreign to you, and you are accustomed to regard it with suspicion, to deny it a scientific status, and to leave it to the general public, poets, mystics, and philosophers. Now this limitation in you is undoubtedly detrimental to your medical efficiency; for on meeting a patient it is the mental aspects with which one first comes into contact, as in most human relationships, and I am afraid you will pay the penalty of having to yield a part of the curative influence at which you aim to the quacks, mystics, and faith-healers whom you despise.

I quite acknowledge that there is an excuse for this defect in your previous training. There is no auxiliary philosophical science that might be of service to you in your profession. Neither speculative philosophy nor descriptive psychology, nor even the so-called experimental psychology which is studied in connection with the physiology of the sense-organs, as they are taught in the schools, can tell you anything useful of the relations existing between mind and body, or can give you a key to comprehension of a possible disorder of the mental functions. It is true that the psychiatric branch of medicine occupies itself with describing the different forms of recognizable mental disturbances and grouping them in clinical pictures, but in their best moments psychiatrists themselves are doubtful whether their purely descriptive formulations deserve to be called science. The origin, mechanism, and interrelation of the symptoms which make up these clinical pictures are undiscovered: either they cannot be correlated with any demonstrable changes in the brain, or only with such changes as in no way explain them. These mental disturbances are open to therapeutic influence only when they can be identified as secondary effects of some organic disease.

This is the lacuna which psycho-analysis is striving to fill. It hopes to provide psychiatry with the missing psychological foundation, to discover the common ground on which a corre-

lation of bodily and mental disorder becomes comprehensible. To this end it must dissociate itself from every foreign preconception, whether anatomical, chemical, or physiological, and must work throughout with conceptions of a purely psychological order, and for this very reason I fear that it will appear strange to you at first.

For the next difficulty I shall not hold you, your training or your mental attitude, responsible. There are two tenets of psycho-analysis which offend the whole world and excite its resentment; the one conflicts with intellectual, the other with moral and aesthetic prejudices. Let us not underestimate these prejudices; they are powerful things, residues of valuable, even necessary, stages in human evolution. They are maintained by emotional forces, and the fight against them is a hard one.

The first of these displeasing propositions of psycho-analysis is this: that mental processes are essentially unconscious, and that those which are conscious are merely isolated acts and parts of the whole psychic entity. Now I must ask you to remember that, on the contrary, we are accustomed to identify the mental with the conscious. Consciousness appears to us as positively the characteristic that defines mental life, and we regard psychology as the study of the content of consciousness. This even appears so evident that any contradiction of it seems obvious nonsense to us, and yet it is impossible for psycho-analysis to avoid this contradiction, or to accept the identity between the conscious and the psychic. The psycho-analytical definition of the mind is that it comprises processes of the nature of feeling, thinking, and wishing, and it maintains that there are such things as unconscious thinking and unconscious wishing. But in doing so psycho-analysis has forfeited at the outset the sympathy of the sober and scientifically minded, and incurred the suspicion of being a phantastic cult occupied with dark and unfathomable mysteries. You yourselves must find it difficult to understand why I should stigmatize an abstract proposition, such as "The psychic is the conscious," as a prejudice; nor can you guess yet what evolutionary process could have led to the denial of the unconscious, if it does indeed exist, nor what advantage could have been achieved by this denial. It seems like an empty wrangle over words to argue whether mental life is to be regarded as co-extensive with consciousness or whether it may be said to stretch beyond this limit, and yet I can assure you that

the acceptance of unconscious mental processes represents a decisive step towards a new orientation in the world and in science.

As little can you suspect how close is the connection between this first bold step on the part of psycho-analysis and the second to which I am now coming. For this next proposition, which we put forward as one of the discoveries of psycho-analysis, consists in the assertion that impulses, which can only be described as sexual in both the narrower and the wider sense, play a peculiarly large part, never before sufficiently appreciated, in the causation of nervous and mental disorders. Nay, more, that these sexual impulses have contributed invaluablely to the highest cultural, artistic, and social achievements of the human mind.

In my opinion, it is the aversion from this conclusion of psycho-analytic investigation that is the most significant source of the opposition it has encountered. Are you curious to know how we ourselves account for this? We believe that civilization has been built up, under the pressure of the struggle for existence, by sacrifices in gratification of the primitive impulses, and that it is to a great extent forever being re-created, as each individual, successively joining the community, repeats the sacrifice of his instinctive pleasures for the common good. The sexual are amongst the most important of the instinctive forces thus utilized: they are in this way sublimated, that is to say, their energy is turned aside from its sexual goal and diverted towards other ends, no longer sexual and socially more valuable. But the structure thus built up is insecure, for the sexual impulses are with difficulty controlled; in each individual who takes up his part in the work of civilization there is a danger that a rebellion of the sexual impulses may occur, against this diversion of their energy. Society can conceive of no more powerful menace to its culture than would arise from the liberation of the sexual impulses and a return of them to their original goal. Therefore society dislikes this sensitive place in its development being touched upon; that the power of the sexual instinct should be recognized, and the significance of the individual's sexual life revealed, is very far from its interests; with a view to discipline, it has rather taken the course of diverting attention away from this whole field. For this reason, the revelations of psycho-analysis are not tolerated by it, and it would greatly prefer to brand them as aesthetically offensive, morally reprehensible, or dangerous. But since such objections are

not valid arguments against conclusions which claim to represent the objective results of scientific investigation, the opposition must be translated into intellectual terms before it can be expressed. It is a characteristic of human nature to be inclined to regard anything which is disagreeable as untrue, and then without much difficulty to find arguments against it. So society pronounces the unacceptable to be untrue, disputes the results of psycho-analysis with logical and concrete arguments, arising, however, in affective sources, and clings to them with all the strength of prejudice against every attempt at refutation.

But we, on the other hand, claim to have yielded to no tendency in propounding this objectionable theory. Our intention has been solely to give recognition to the facts as we found them in the course of painstaking researches. And we now claim the right to reject unconditionally any such introduction of practical considerations into the field of scientific investigation, even before we have determined whether the apprehension which attempts to force these considerations upon us is justified or not.

These, now, are some of the difficulties which confront you at the outset when you begin to take an interest in psycho-analysis. It is probably more than enough for a beginning. If you can overcome their discouraging effect, we will proceed further.

## SECOND LECTURE

### THE PSYCHOLOGY OF ERRORS

WE SHALL NOW begin, not with postulates, but with an investigation. For this purpose we shall select certain phenomena which are very frequent, very familiar and much overlooked, and which have nothing to do with illness, since they may be observed in every healthy person. I refer to the errors that everyone commits: as when anyone wishes to say a certain thing but uses the wrong word (slip of the tongue); or when the same sort of mistake is made in writing (slip of the pen), in which case one may or may not notice it; or when anyone reads in print or writing something other than what is actually before him (misreading); or when anyone mis-hears what is said to him, naturally when there is no question of any disease of the auditory sense-organ. Another series of such phenomena are those based on forgetting something temporarily, though not permanently; as, for instance, when anyone cannot think of a

name which he knows quite well and is always able to recognize whenever he sees it; or when anyone forgets to carry out some intention, which he afterwards remembers, and has therefore forgotten only for a certain time. This element of transitoriness is lacking in a third class, of which mislaying things so that they cannot be found is an example. This is a kind of forgetfulness which we regard differently from the usual kind; one is amazed or annoyed at it, instead of finding it comprehensible. Allied to this are certain *mistakes*, in which the temporary element is again noticeable, as when one believes something for a time which both before and afterwards one knows to be untrue, and a number of similar manifestations which we know under various names.

Some inner relation between all these kinds of occurrences is indicated in German, by the use of the prefix *ver* which is common to all the words designating them. These words almost all refer to acts of an unimportant kind, generally temporary and without much significance in life. It is only rarely that anything of the kind, such as the loss of some object, attains any practical importance. For this reason little attention is paid to such happenings and they arouse little feeling.

I am now going to ask you to consider these phenomena. But you will object, with annoyance: "There are so many tremendous puzzles both in the wide world and in the narrower life of the soul, so many mysteries in the field of mental disorder which demand and deserve explanation, that it really seems frivolous to waste labour and interest on these trifles. If you could explain to us how it is possible for anyone with sound sight and hearing, in broad daylight, to see and hear things which do not exist, or how anyone can suddenly believe that his nearest and dearest are persecuting him, or can justify with the most ingenious arguments a delusion which would seem nonsensical to any child, then we might be willing to take psycho-analysis seriously. But if psycho-analysis cannot occupy us with anything more interesting than the question why a speaker uses a wrong word or why a *Hausfrau* mislays her keys and similar trivialities, then we shall find something better to do with our time and our interest."

My reply is: Patience! Your criticism is not on the right track. It is true that psycho-analysis cannot boast that it has never occupied itself with trifles. On the contrary, the material of its observations is usually those commonplace occurrences which have been cast aside as

all too insignificant by other sciences, the refuse, so to speak, of the phenomenal world. But in your criticism are you not confounding the magnitude of a problem with the conspicuous nature of its manifestations? Is it not possible, under certain conditions and at certain times, for very important things to betray themselves in very slight indications? I could easily cite many instances of this. What slight signs, for instance, convey to the young men in my audience that they have gained a lady's favour? Do they expect an explicit declaration, a passionate embrace, or are they not content with a glance which is almost imperceptible to others, a fleeting gesture, a handshake prolonged by a second? Or suppose you are a detective engaged in the investigation of a murder, do you actually expect to find that the murderer will leave his photograph with name and address on the scene of the crime? Are you not perforce content with slighter and less certain traces of the person you seek? So let us not under-value small signs: perhaps from them it may be possible to come upon the tracks of greater things. Besides, I think as you do that the larger problems of the world and of science have the first claim on our interest. But on the whole it avails little to form a definite resolution to devote oneself to the investigation of this or that great problem. One is then often at a loss how to set about the next step. In scientific work it is more profitable to take up whatever lies before one whenever a path towards its exploration presents itself. And then, if one carries it through thoroughly, without prejudice or pre-conceptions, one may, with good fortune and by virtue of the interrelationship linking each thing to every other (hence, also, the small to the great), find, even in the course of such humble labour, a road to the study of the great problems.

It is from this point of view that I hope to enlist your interest in considering the apparently trivial errors made by normal people. I propose now that we question someone who has no knowledge of psycho-analysis as to how he explains these occurrences.

His first answer is sure to be: "Oh, they are not worth any explanation; they are little accidents." What does the man mean by this? Does he mean to maintain that there are any occurrences so small that they fail to come within the causal sequence of things, that they might as well be other than they are? Anyone thus breaking away from the determination of natural phenomena, at any single point, has thrown

over the whole scientific outlook on the world (*Weltanschauung*). One may point out to him how much more consistent is the religious outlook on the world, which emphatically assures us that "not one sparrow shall fall to the ground" except God wills it. I think our friend would not be willing to follow his first answer to its logical conclusion; he would give way and say that if he were to study these things he would soon find some explanation of them. It must be a matter of slight functional disturbances, of inaccuracies of mental performance, the conditions of which could be discovered. A man who otherwise speaks correctly may make a slip of the tongue, (1) when he is tired or unwell, (2) when he is excited, or (3) when his attention is concentrated on something else. It is easy to confirm this. Slips of the tongue do indeed occur most frequently when one is tired, or has a headache, or feels an attack of migraine coming on. Forgetting proper names very often occurs in these circumstances; many people are habitually warned of the onset of an attack of migraine by the inability to recall proper names. In excitement, too, one mixes up words or even things, one performs actions erroneously; and the forgetting of intentions, as well as a number of other undesigned acts, comes to the fore when one is distracted, in other words, when the attention is concentrated on other things. A familiar instance of such distraction is the professor in *Fliegende Blätter* who forgets his umbrella and takes the wrong hat, because he is thinking of the problems which are to be the subject of his next book. We all know from our own experience how one can forget to carry out intentions or promises when something has happened in the interval that absorbs one very deeply.

This seems so entirely comprehensible and also irrefutable. It is perhaps not very interesting or not so much so as we expected. Let us look at this explanation of errors more closely. The various conditions which have been cited as necessary for the occurrence of these phenomena are not all similar in kind. Illness and disorders of the circulation afford a physiological basis for an affection of the normal functions; excitement, tiredness, and distraction are conditions of a different kind which could be described as psycho-physiological. These last could easily be converted into a theory. Fatigue, as well as distraction, and perhaps also general excitement, cause a dissipation of the attention from which it may follow that the act in question has insufficient attention de-

voted to it. It can then very easily be disturbed and inexactly performed. Slight illness or a change in the distribution of blood in the central organ of the nervous system can have the same effect, by these conditions affecting the determining factor, the distribution of attention, in a similar way. In all cases it would be a question of the effects of a disturbance of the attention from organic or psychical causes.

But all this doesn't seem to promise much of interest for a psycho-analytic investigation. We might feel tempted to give up the topic. To be sure, a closer inspection of the facts shows that they are not all in accord with the *attention* theory of errors of this sort, or at least that not everything can be directly deduced from it. We find that such errors and such forgetfulness also take place when people are not fatigued or excited, but are in every way in their normal condition; unless, just because of the errors, we were subsequently to attribute to them a condition of excitement which they themselves did not acknowledge. Nor can the matter be quite so simple as that the successful performance of an act will be ensured by an intensification of attention, or endangered by a diminution of it. For a great number of actions may be carried out in a purely automatic way with very little attention and yet quite successfully. In walking, a man may perhaps scarcely know where he is going but keep to the right road and stop at his destination without having gone astray. At least, this is what usually happens. A practised pianist strikes the right notes without thinking of them. He may of course also make an occasional mistake, but if automatic playing increased the danger of errors the virtuoso, whose constant practice has made his playing entirely automatic, would be the most exposed to this danger. Yet we see, on the contrary, that many acts are most successfully carried out when they are not the objects of particularly concentrated attention, and that mistakes may occur just on occasions when one is most eager to be accurate, that is, when a distraction of the necessary attention is most certainly not present. One could then say that this is the effect of the *excitement*, but we do not understand why the excitement does not rather intensify the concentration on the end so much desired. So that if in an important speech anyone says the opposite of what he intends, it can hardly be explained according to the psycho-physiological or the attention theory.

There are also many other minor features in

connection with these errors which we do not understand and which are not rendered more comprehensible by these explanations. For instance, when one has temporarily forgotten a name one is annoyed, one is determined to recall it and cannot desist from the attempt. Why is it that despite this annoyance the person so often cannot succeed, as he wishes, in directing his attention to the word which, as he says, is "on the tip of his tongue," and which he instantly recognizes when it is supplied to him? Or, to take another example, there are cases in which the errors multiply, link themselves together or act as substitutes for one another. The first time, one forgets an appointment; the next time, after having made a special resolution not to forget it, one discovers that one has made a mistake in the day or hour. Or one tries by devious ways to remember a forgotten word, and in the course of so doing loses track of a second name which would have been of use in finding the first. If one then pursues the second name, a third gets lost, and so on. It is notorious that the same thing happens with misprints, which are of course errors on the part of the compositor. A stubborn error of this sort is said once to have crept into a Social-Democratic newspaper, where, in the account of a festivity, the following words were printed: "Amongst those present was His Highness, the Clown Prince." The next day a correction was attempted. The paper apologized and said: "The sentence should of course have read, 'the Crow-Prince.'" Again, in a war-correspondent's account of meeting a famous general whose infirmities were pretty well known, a reference to the general was printed as "this battle-scared veteran." Next day an apology appeared which read "the words of course should have been 'the bottle-scarred veteran!'"<sup>1</sup> We like to attribute these occurrences to a devil in the type-setting machine or to some malevolent goblin—figurative expressions which at least imply something more than a psycho-physiological theory of the misprint.

I do not know if you are aware of the fact that slips of the tongue can be provoked, called forth by suggestion, as it were. An anecdote will serve to illustrate this. Once when a novice on the stage was entrusted with the important part in *The Maid of Orleans* of announcing to the King: "The Constable sends back his sword," the principal player, during the rehearsal, played the joke of several times repeating to the timid beginner, instead of the

<sup>1</sup> English example.—TR.

text, the following: "The *Komfortabel* sends back his steed."<sup>1</sup> At the performance the unfortunate actor actually made his *début* with this perverse announcement, though he had been amply warned against so doing, or perhaps just because he had been.

All these little characteristics of errors are not much illuminated by the theory of diverted attention. But that does not necessarily prove the theory wrong. There may be something missing, a link, by the addition of which the theory might be made completely satisfactory. But many of the errors themselves can be considered from another aspect.

Let us select slips of the tongue, as the type of error best suited to our purpose. We might equally well choose slips of the pen or of reading. Now we must first remind ourselves that, so far, we have only enquired when and under what conditions the wrong word is said, and have received an answer on that point only. Interest may be directed elsewhere, though, and the question raised why just this particular slip is made and no other: one can consider the nature of the mistake. You will see that so long as this question remains unanswered, and the *effect* of the mistake is not explained, the phenomenon remains a pure accident on the psychological side, even if a physiological explanation has been found for it. When it happens that I make a mistake in a word I could obviously do this in an infinite number of ways, in place of the right word substitute any one of a thousand others, or make innumerable distortions of the right word. Now, is there anything which forces upon me in a specific instance just this one special slip, out of all those which are possible, or does that remain accidental and arbitrary, and can nothing rational be found in answer to this question?

Two authors, Meringer and Mayer (a philologist and a psychiatrist) did indeed in 1895 make an attempt to approach the problem of slips of the tongue from this side. They collected examples and first treated them from a purely descriptive standpoint. This of course does not yet furnish any explanation, but it may lead the way to one. They differentiated the distortions which the intended phrase suffered through the slip into: interchanges (in the positions of words, syllables or letters), anticipations, perseverations, compoundings (contaminations), and substitutions. I will give

you examples of these authors' main categories. As an instance of an interchange (in the position of words) someone might say "The Milo of Venus" instead of "The Venus of Milo." The well-known slip of the hotel-boy who, knocking at the bishop's door, nervously replied to the question "Who is it?" "The Lord, my boy!" is another example of such an interchange in the position of words.<sup>2</sup> In the typical Spoonerism, the position of certain letters is interchanged, as when the preacher said: "How often do we feel a half-warmed fish within us!"<sup>3</sup> It is a case of anticipation if any one says: "The thought lies heartily . . ." instead of: "The thought lies heavily on my heart." A perseveration is illustrated by the well-known ill-fated toast, "Gentlemen, I call upon (*auf*) you to

*hiccough* (= *aufzustossen*)  
(*auf*) to the health of  
our Chief."

(drink) (= *anzustossen*)

And when a member of the House of Commons referred to another as the "honourable member for Central *Hell*," instead of "Hull," it was a case of perseveration; as also when a soldier said to a friend "I wish there were a thousand of our men *mortified* on that hill, Bill," instead of "fortified." In one case the *ell* sound has perseverated from the previous words "member for Central," and in the other the *m* sound in "men" has perseverated to form "mortified."<sup>3</sup> These three types of slip are not very common. You will find those cases much more frequent in which the slip happens by a compounding or contraction, as for example when a gentleman asks a lady if he may *insort* her on her way (*begleit-digen*); this contraction is made up of *begleiten*=to escort, and *beleidigen*=to insult. (And by the way, a young man addressing a lady in this way will not have much success with her.) A substitution takes place when a poor woman says she has an "incurable *infernal* disease," or in Mrs. Malaprop's mind when she says, for instance, "few gentlemen know how to value the *ineffectual* qualities in a woman."<sup>3</sup>

The explanation which the two authors attempt to formulate as the basis of their collection of examples is peculiarly inadequate. They hold that the sounds and syllables of a word have different values and that the innervation of the sounds of higher value can interfere with those of lower value. They obviously base this conclusion on the cases of

<sup>1</sup> *Komfortabel* is a slang Viennese expression for a one-horse cab.—Tr.

<sup>2</sup> English examples.—Tr.

anticipation and perseveration which are not at all frequent; in other forms of slips of the tongue the question of such sound priorities, even if they exist, does not enter at all; for the most frequent type of slip is that in which instead of a certain word one says another which resembles it, and this resemblance is considered by many people sufficient explanation of it. For instance, a professor may say in his opening lecture, "I am not inclined (*geneigt* instead of *geeignet*=fitted) to estimate the merits of my predecessor." Or another professor says, "In the case of the female genital, in spite of the *tempting* . . . I mean, the *attempted* . . ." (*Versuchungen* instead of *Versuche*).

The commonest and also the most noticeable form of slip of the tongue, however, is that of saying the exact opposite of what one meant to say. These cases are quite outside the effect of any relations between sounds or confusion due to similarity, and in default one may therefore turn to the fact that opposites have a strong conceptual connection with one another and are psychologically very closely associated. There are well-known examples of this sort. For instance, the President of our Parliament once opened the session with the words "Gentlemen, I declare a quorum present and herewith declare the session *closed*."

Any other common association may work in a way as insidious as the association of opposites and may on occasion lead to results as inopportune. So there is a story to the effect that, at a festivity in honour of the marriage of a child of H. Helmholtz with a child of the well-known inventor and captain of industry, W. Siemens, the famous physiologist Dubois-Reymond was asked to speak. He concluded his doubtless brilliant speech with the toast "Success to the new partnership, Siemens and *Halske!*" which was of course the name of the old firm. The association of the two names must have been as familiar to a resident in Berlin as "Cross & Blackwell" to a Londoner.

So the effect of word-associations must be taken into account, as well as that of sound-values and similarities between words. But even that is not enough. In one type of case, before we can arrive at an adequate explanation of the slip we must consider some phrase which had been said, or perhaps only thought, previously. Again, that is, a case of perseveration, as Meringer insists, but arising in a more distant source.—I must confess that altogether I have the impression that we are further than ever from comprehension of slips of the tongue.

However, I hope I am not mistaken in thinking that in the course of our examination of the above examples an impression has formed itself in us which may be of a kind to repay further attention. We were considering the general conditions under which slips of the tongue occur and then the influences which determine the kind of distortion effected in the slip, but so far we have not examined at all the result of the slip itself, as an object of interest without regard to its origin. If we bring ourselves to do this we shall in the end have to assert courageously that in some of the examples the slip itself makes sense. Now what does it mean when we say "it makes sense"? Well, it means that the result of the slip may perhaps have a right to be regarded in itself as a valid mental process following out its own purpose, and as an expression having content and meaning. Hitherto we have only spoken of errors, but now it appears as if the error could sometimes be quite a proper act, except that it has intruded itself in the place of one more expected or intended.

In certain cases the sense belonging to the slip itself appears obvious and unmistakable. When the President in his opening speech closes the session of Parliament, a knowledge of the circumstances under which the slip was made inclines us to see a meaning in it. He expects no good result from the session and would be glad to be able to disperse forthwith; there is no difficulty in discovering the meaning, or interpreting the sense, of this slip. Or when a lady, appearing to compliment another, says "I am sure *you* must have *thrown* this delightful hat together" instead of "sewn it together" (*aufgepatzt* instead of *aufgeputzt*), no scientific theories in the world can prevent us from seeing in her slip the thought that the hat is an amateur production. Or when a lady who is well known for her determined character says: "My husband asked his doctor what sort of diet ought to be provided for him. But the doctor said he needed no special diet, he could eat and drink whatever *I* choose," the slip appears clearly as the unmistakable expression of a consistent scheme.

Now supposing it should turn out that not only a few cases of slips of the tongue and errors in general, but the great majority of them, have a meaning, then the meaning of the error, to which we have hitherto paid no attention, would become the point of greatest interest to us and would justifiably drive all other points of view into the background. All

physiological and psycho-physiological conditions could then be ignored and attention could be devoted to the purely psychological investigation of the *sense*, that is, the meaning, the intention, in the errors. With this in view, therefore, we shall soon consider further material.

Before undertaking this, however, I should like to invite you to follow up another clue with me. It often happens that a poet makes use of a slip of the tongue or some other error as a means of artistic expression. This fact in itself proves that he thinks the error, for instance, a slip of the tongue, has a meaning; for he constructs it intentionally. It could hardly happen that a poet accidentally made a slip of the pen and then allowed his slip of the pen to stand as a slip of the tongue of the character. He wishes to reveal something by means of the slip and we may well enquire what that may be—whether perhaps he wishes to indicate that the person in question is distracted or overtired, or is expecting a headache. Of course we should not exaggerate the importance of it if poets do make use of slips to express their meaning. Slips might be in reality without meaning, accidents in the mental world, or only occasionally have a meaning, and poets would still be entitled to refine them by infusing sense into them for their own purposes. However, it would not be surprising if more were to be learned from poets about slips of the tongue than from philologists and psychiatrists.

There is an example of a slip of this kind in Schiller's *Wallenstein* (Piccolomini, Act I, Scene 5). In the foregoing scene, young Max Piccolomini had taken up Duke Wallenstein's cause ardently, and had been passionately describing the blessings of peace, which he had become aware of in the course of a journey accompanying Wallenstein's beautiful daughter to the camp. As he leaves the stage, his father (Octavio) and the courtier Questenberg are plunged in consternation. The fifth scene continues:

QUESTENBERG. Alas! and stands it so?

Friend, do we let him go

In this delusion? let him go from us?

Not call him back at once, not

Open his eyes here and now?

OCTAVIO (*recovering himself out of deep thought*).

He has now opened *mine*

And I see more than pleases me.

QUESTENBERG. What is it?

OCTAVIO. A curse upon this journey!

QUESTENBERG. But why so? What is it?

OCTAVIO. Come, come, friend! I must up

And follow the ill-omened clue at once

And see with mine own eyes—come with me now!

QUESTENBERG. What now? Where go you then?

OCTAVIO (*hastily*). To her, herself!

QUESTENBERG. To . . .

OCTAVIO (*corrects himself*). To the Duke! Come, let us go.

Octavio meant to say: "To him, to the Duke," but his tongue slips and he betrays (to us, at least) by the words "to her" that he has clearly recognized the influence at work behind the famous young warrior's rhapsodies in favour of peace.

A still more impressive example was found by O. Rank in Shakespeare. It occurs in the *Merchant of Venice*, in the famous scene in which the fortunate suitor makes his choice among the three caskets; and I can perhaps not do better than read to you now Rank's short account of it.

"A slip of the tongue which occurs in Shakespeare's *Merchant of Venice* (Act III, Sc. 2) is exceedingly fine in the poetic feeling it shows and in the brilliant way in which it is applied technically. Like the slip in Wallenstein quoted by Freud in his *Psycho-pathology of Everyday Life*, it shows that the poets well understand the mechanism and meaning of such slips and assume that the audience will also understand them. Portia, who by her father's wish has been bound to the choice of a husband by lot, has so far escaped all the unwelcome suitors by the luck of fortune. Having at last found in Bassanio the suitor to whom she is inclined, she fears that he too will choose the wrong casket. She would like to tell him that even so he may rest assured of her love, but she is prevented by her oath. In this inner conflict the poet makes her say to her chosen suitor:

I pray you tarry; pause a day or two,

Before you hazard: for, in choosing wrong,

I lose your company; therefore, forbear awhile:

There's something tells me (but it is not love)

I would not lose you . . .

. . . I could teach you

How to choose right, but then I am forsworn;

So will I never be; so may you miss me;

But if you do you'll make me wish a sin,

That I had been forsworn. Beshrew your eyes,

They have o'erlooked me, and divided me;

One half of me is yours, the other half yours,—

Mine own, I would say; but if mine, then yours,

And so all yours.

Just that which she only meant to indicate subtly to him because she should really have

concealed it from him altogether, namely, that even before the lot she was his and loved him, this the poet with exquisite fineness of psychological feeling causes to come to expression in her slip; and is able, by this artistic device, to relieve the unbearable uncertainty of the lover as well as the suspense of the audience as to the issue of the choice."

And notice, at the end, how subtly Portia reconciles the two declarations which are contained in the slip, how she resolves the contradiction between them, and finally even justifies the slip.

... but if mine, then yours,

And so all yours.

It has happened that other thinkers outside the field of medicine have disclosed by an observation the meaning of some error and so anticipated our efforts in this direction. You all know the witty satirist Lichtenberg (1742-1799) of whom Goethe said: "Where he makes a joke, a problem lies concealed." And occasionally the solution of the problem is revealed in the joke. Lichtenberg writes in his witty and satirical *Notes*, "He always read *Agamemnon* for *angenommen* (verb meaning to take for granted), so deeply versed was he in Homer." This really contains the whole theory of slips in reading.

At the next lecture we will see whether we can agree with the poets in their conception of the meaning of psychological errors.

### THIRD LECTURE

#### THE PSYCHOLOGY OF ERRORS (*Continued*)

AT THE last lecture it occurred to us to consider the error by itself alone, apart from its relation to the intended act with which it had interfered, and we perceived that in certain cases it seemed to betray a meaning of its own. We said to ourselves that if this conclusion, that the error has its own meaning, could be established on a larger scale, that meaning would soon prove more interesting to us than the investigation of the conditions under which errors arise.

Let us once more agree upon what we understand by the *meaning* of a mental process. This is nothing else but the intention which it serves and its place in a mental sequence. In most of the cases we examined we could substitute for the word *meaning* the words *intention* and *tendency*. Now was it only a deceptive appearance, or a poetic glorification of the error, that led us to believe that we could see an intention in it?

Let us still keep to the examples of slips of the tongue and review a larger number of such manifestations. We then find whole categories of cases in which the intention, the meaning, of the slip is quite obvious, particularly so in those instances in which the opposite of what was intended is said. The President says in his opening speech: "I declare the session *closed*." That is surely not ambiguous. The meaning and intention of this slip is that he wants to close the session. One might well say, "he said so himself"; we only take him at his word. Please do not interrupt me with the objection that this is impossible, that we know quite well that he wished to open the session, not to close it, and that he himself whom we have just recognized as the best judge of his intention will affirm that he meant to open it. In doing so you forget that we agreed to consider the error by itself; its relation to the intention which it disturbs will be discussed later. *You* would be guilty of an error in logic, by which you would conveniently dispose of the problem under discussion, which in English is called begging the question.

In other cases, where the form of the slip is not exactly the opposite of what is intended, a contradictory sense may still often come to expression. "I am not *inclined* (*geneigt*) to appreciate my predecessor's merits." *Inclined* is not the opposite of *in a position to* (*geeignet*), but it is an open confession of a thought in sharpest contradiction to the speaker's duty to meet the situation gracefully.

In still other cases, the slip simply adds a second meaning to the intended. The sentence then sounds like a contraction, an abbreviation, a condensation of several sentences into one. Thus the determined lady who said: "He may eat and drink whatever *I* choose." That is as if she had said: "He can eat and drink what he chooses, but what does it matter what he chooses? It is for me to do the choosing!" Slips of the tongue often give this impression of abbreviation; for instance, when a professor of anatomy at the end of his lecture on the nasal cavities asks whether his class has thoroughly understood it and, after a general reply in the affirmative, goes on to say: "I can hardly believe that that is so, since persons who can thoroughly understand the nasal cavities can be counted, even in a city of millions, on *one finger* . . . I mean, on the fingers of one hand." The abbreviated sentence has its own meaning; it says that there is only one person who understands the subject.

In contrast to these types in which the slip

plainly discloses its meaning are others in which the slip of the tongue conveys nothing intelligible, and therefore directly controverts our expectations. The mis-pronunciation by mistake of proper names, or the enunciation of meaningless sounds, is such a frequent occurrence that this alone would appear to dispose at once of the question whether all errors have a meaning. Yet closer inspection of such examples discloses the fact that it is easily possible to understand such distortions; indeed, that the difference between these unintelligible cases and the previous more comprehensible ones is not so very great.

The owner of a horse, on being asked how it was, replied: "O, it may *stad*—it may *take* another month." Asked what he really meant to say, he answered that he was thinking it was a *sad* business, and the words *sad* and *take* together gave rise to *stad*. (Meringer and Mayer.)

Another man was relating some objectionable incidents and went on: "and then certain facts were *refilled*." He explained that he meant to say these facts were *filthy*. *Revealed* and *filthy* together combine to form *refilled*. (Meringer and Mayer.)

You will recall the case of the young man who offered to "insort" an unknown lady. We took the liberty of resolving this word into *insult* and *escort*, and were quite convinced of this interpretation without requiring proof of it. From these examples you can see that even these more obscure cases can be explained as the concurrence, or *interference*, of two different intentions of speech with one another; the differences arise only in that in the first type of slip the one intention has entirely excluded the other, as when the opposite is said; while in the second type the one intention only succeeds in distorting or modifying the other, from which arise combinations of a more or less senseless appearance.

We believe that we have now discovered the secret of a large number of slips of the tongue. If we keep this clear in mind we shall be able to comprehend still further groups hitherto entirely mysterious. Although, for instance, in a case of distortion of a name we cannot suppose that it is always a matter of a contest between two similar but different names, yet the second intention is easily perceived. Distortions of names are common enough apart from slips of the tongue; they are attempts to liken the name to something derogatory or degrading, a common form of abuse, which educated persons soon learn to avoid but nevertheless do not

willingly give up. It may be dressed up as a joke, although one of a very low order. To quote one gross and ugly example of such a distortion of a name, the name of the President of the French Republic, *Poincaré*, has lately been transformed into *Schweinskarre*. It is not going much further to assume that some such abusive intention may also be behind distortions of names produced by a slip of the tongue. In pursuing our idea, similar explanations suggest themselves for cases of slips where the effect is comic or absurd. In the case of the member of parliament who referred to the "honourable member for Central Hell," the sober atmosphere of the House is unexpectedly disturbed by the intrusion of a word that calls up a ludicrous and unflattering image; we are bound to conclude from the analogy with certain offensive and abusive expressions that an impulse has interposed here, to this effect: "You needn't be taken in. I don't mean a word of this. To hell with the fellow!" The same applies to slips of the tongue which transform quite harmless words into obscene and indecent ones.<sup>1</sup>

We are familiar with this tendency in certain people intentionally to convert harmless words into indecent ones for the sake of the amusement obtained; it passes for wit, and in fact when one hears of a case one at once asks whether it was intended as a joke or occurred unintentionally as a slip of the tongue.

Well, we seem to have solved the riddle of errors with comparatively little trouble! They are not accidents; they are serious mental acts; they have their meaning; they arise through the concurrence—perhaps better, the mutual interference—of two different intentions. But now I can well understand that you want to overwhelm me with a flood of questions and doubts, which must be answered and resolved before we can enjoy this first result of our efforts. I certainly do not want to press any hasty conclusions upon you. Let us coolly consider everything in turn.

What would you like to say? Whether I think that this explanation accounts for all cases of slips of the tongue or only for a certain number? Whether this conception can be extended to the many other types of errors, to misreading, slips of the pen, forgetting, wrongly performed actions, mislaying things and so on? What part the factors of fatigue, excitement,

<sup>1</sup> Two untranslatable examples are given in the text, *apopos* for a *propos* and *Eischeissweibchen* for *Eiweissweibchen*. (Meringer and Mayer.)—TR.

absent-mindedness and distraction of attention play in regard to the mental nature of errors? Besides this, it is clearly seen that of the two competing meanings in the slip one is always manifest, but not always the other. How is one to arrive at the latter? And if one believes that one has guessed it, how is one to find proof that this is not merely a probability but the only true meaning? Is there anything else you wish to ask? If not, then I myself will continue. I will remind you that we are not really greatly concerned with errors in themselves, but that we wished to learn from a study of them something of value from the point of view of psycho-analysis. Therefore I will put this question: "What sort of purposes or tendencies are these which thus interfere with other intentions, and what is the relation between the interfering tendency and the other?" Thus, as soon as we have found the answer to the riddle, our efforts begin again.

Very well then; is this the explanation of all cases of slips of the tongue? I am very much inclined to think so, and for this reason, because whenever one examines an instance of it this type of solution may be found. Still, one cannot prove that a slip of the tongue cannot come to pass without the agency of this mechanism. It may be so: for our purposes it is a matter of indifference, theoretically; for the conclusions which we wish to draw by way of an introduction to psycho-analysis remain valid, even if only a small proportion of the total incidence of slips of the tongue comes under our explanation, and this is certainly not so. The next question, whether this explanation extends to other forms of errors, may be answered by way of anticipation in the affirmative. You can convince yourselves of it when we turn to consider examples of slips of the pen, of wrongly performed acts, and so on. I propose, however, for technical reasons that we should postpone doing this until we have investigated the slip of the tongue itself more thoroughly.

The question what significance those factors, which some writers have placed in the foreground, can now have for us—such factors as disturbances of the circulation, fatigue, excitement, distraction, disturbances of attention—demands a more exhaustive reply if we assume the mental mechanism of slips described above. You will notice that we do not deny these factors. Indeed, in general it doesn't often happen that psycho-analysis contests anything which is maintained in other quarters; as a rule, psy-

cho-analysis only adds something new to what has been said; and it does certainly happen on occasion that what has hitherto been overlooked, and is now supplied by psycho-analysis, is the most essential part of the matter. The influence of such physiological predispositions as arise in slight illness, circulatory disturbances and conditions of fatigue, upon the occurrence of slips of the tongue is to be admitted without more ado; everyday personal experience may convince you of it. But how little is explained by this admission! Above all, these are not necessary conditions of errors. Slips of the tongue may just as well occur in perfect health and normal conditions. These bodily factors, therefore, are merely contributory; they only favour and facilitate the peculiar mental mechanism which produces slips of the tongue. I once used an illustration for this state of things which I will repeat here, as I know of no better. Just suppose that on some dark night I am walking in a lonely neighbourhood and am assaulted by a rogue who seizes my watch and money, whereupon since I could not see the robber's face clearly, I make my complaint at the police-station in these words: "Loneliness and darkness have just robbed me of my valuables." The police officer might reply to me: "You seem to carry your support of the extreme mechanistic point of view too far for the facts. Suppose we put the case thus: Under cover of darkness and encouraged by the loneliness of the spot, some unknown thief has made away with your valuables. It appears to me that the essential thing to be done is to look about for the thief. Perhaps we shall then be able to take the plunder from him again."

Psycho-physiological factors such as excitement, absent-mindedness, distraction of attention, obviously provide very little in the way of explanation. They are mere phrases; they are screens, and we should not be deterred from looking behind them. The question is rather what has here called forth the excitement or the particular diversion of attention. The influence of sound-values, resemblances between words, and common associations connecting certain words, must also be recognized as important. They facilitate the slip by pointing out a path for it to take. But if there is a path before me, does it necessarily follow that I must go along it? I also require a motive to determine my choice and, further, some force to propel me forward. These sound-values and word associations are, therefore, just like the bodily conditions, the facilitating causes of

slips of the tongue, and cannot provide the real explanation of them. Consider for a moment the enormous majority of cases in which the words I am using in my speech are not deranged on account of sound-resemblance to other words, intimate associations with opposite meanings, or with expressions in common use. It yet remains to suppose, with the philosopher Wundt, that a slip of the tongue arises when the tendency to associations gains an ascendancy over the original intention owing to bodily fatigue. This would be quite plausible if experience did not controvert it by the fact that in a number of cases the bodily, and in another large group the associative, predisposing causes are absent.

Particularly interesting to me, however, is your next question, namely, by what means the two mutually disturbing tendencies may be ascertained. You probably do not suspect how portentous this question is. You will agree that one of these tendencies, the one which is interfered with, is always unmistakable; the person who commits the slip knows it and acknowledges it. Doubt and hesitation only arise in regard to the other, what we have called the interfering tendency. Now we have already heard, and you will certainly not have forgotten, that in a certain number of cases this other tendency is equally plain. It is evident in the result of the slip if only we have the courage to let the slip speak for itself. The President who said the opposite of what he meant—it is clear that he wishes to open the session, but equally clear that he would also like to close it. That is so plain that it needs no interpreting. But in the other cases, in which the interfering tendency merely distorts the original without itself coming to full expression, how can the interfering tendency be detected in the distortion?

In one group of cases by a very safe and simple method, by the same method, that is, by which we establish the tendency that is interfered with. We enquire of the speaker, who tells us then and there; after making the slip he restores the word he originally intended. "O, it may *stad*—no, it may *take* another month." Well, the interfering tendency may be likewise supplied by him. We say, "Now why did you first say *stad*?" He replies, "I meant to say it was a sad business"; and in the other case in which "refilled" was said, the speaker informs you that he first meant to say it was a filthy business, but controlled himself and substituted another expression. The discovery

of the disturbing tendency is here as definitely established as that of the disturbed tendency. It is not without intention that I have selected as examples cases which owe neither their origin nor their explanation to me or to any supporter of mine. Still, in both these cases, a certain intervention was necessary in order to produce the explanation. One had to ask the speaker why he made the slip, what explanation he could give. Without that he might have passed it by without seeking to explain it. Being asked, however, he gave as his answer the first idea that occurred to him. And see now, this little intervention and the result of it constitute already a psycho-analysis, a prototype of every psycho-analytic investigation that we may undertake further.

Now, should I be too suspicious if I were to surmise that, at the very moment at which psycho-analysis begins to dawn upon you, a resistance to it instantly raises itself within your mind? Are you not eager to object that information supplied by the person enquired of, who committed the slip, is not completely reliable evidence. He naturally wishes, you think, to meet your request to explain his slip, and so he says the first thing that he can think of, if it will do at all. There is no proof that that is actually how the slip arose. It may have been so, but it may just as well have been otherwise. Something else also might have occurred to him that would have met the case as well or even better.

It is remarkable how little respect you have, in your hearts, for a mental fact! Imagine that someone had undertaken a chemical analysis of a certain substance and had ascertained that one ingredient of it is of a certain weight, so and so many milligrams. From this weight, thus arrived at, certain conclusions may be drawn. Do you think now it would ever occur to a chemist to discredit these conclusions on the ground that the isolated substance might as well have had some other weight? Everyone recognizes the fact that it actually had this weight and no other, and builds further conclusions confidently on that fact. But when it is a question of mental fact, that it *was* such an idea and no other that occurred to the person when questioned, you will not accept that as valid, but say that something else might as well have occurred to him! The truth is that you have an illusion of a psychic freedom within you which you do not want to give up. I regret to say that on this point I find myself in sharpest opposition to your views.

Now you will break off here only to take up your resistance at another point. You will continue: "We understand that it lies in the peculiar technique of psycho-analysis to bring the person analysed to give the solution of its problems. Let us take another example, that in which the after-dinner speaker calls upon the company to *hiccough* to the health of their guest. The interfering tendency is, you say, in this case to ridicule; this it is which opposes the intention to do honour. But this is a mere interpretation on your part, based on observations made independently of the slip. If in this case you were to question the perpetrator of the slip he would not confirm your view that he intended an insult; on the contrary, he would vehemently deny it. Why do you not abandon your undemonstrable interpretation in the face of this flat denial?"

Yes, this time you have lighted upon something formidable. I can picture to myself that unknown speaker; he is probably an assistant of the guest of honour, perhaps already a junior lecturer himself, a young man with the brightest prospects. I will press him and ask whether he is sure he did not perceive some feeling in himself antagonistic to the demand that he should pay honour to his chief. A nice fuss there is! He becomes impatient and suddenly bursts out at me: "Look here, enough of this cross-examination, or I'll make myself disagreeable! You will ruin my career with your suspicions. I simply said *aufstossen* instead of *anstossen*, because I'd already said *auf* twice before it. It's the thing that Meringer calls a perseveration, and there's nothing else to be read into it. Do you understand me? That's enough." H'm, this is a startling reaction, a truly energetic repudiation. I see that there is nothing more to be done with the young man, but I think to myself that he betrays a strong personal interest in making out that his slip has no meaning. You will perhaps agree too that he has no right to become so uncivil over a purely theoretical investigation, but after all, you will think, he must know what he wanted to say and what not.

O, so he must? That is perhaps still open to question.

Now you think you have me in a trap. "So that is your technique," I hear you say. "When the person who commits a slip gives an explanation which fits your views then you declare him to be the final authority on the subject. He says so himself! But if what he says does not suit your book, then you suddenly

assert that what he says does not count, one need not believe it."

Certainly that is so. But I can give you another instance of a similarly monstrous procedure. When an accused man confesses to a deed the judge believes him, but when he denies it the judge does not believe him. Were it otherwise the law could not be administered, and in spite of occasional miscarriages you will admit that the system, on the whole, works well.

"Well, but are you a judge, and is the person who commits a slip to be accused before you? Is a slip of the tongue a crime?"

Perhaps we need not reject even this comparison. But see now to what deep-seated differences our attempt to investigate the apparently harmless problems of errors has brought us, differences which at this stage we do not know in the least how to reconcile. I suggest that we should make a temporary compromise on the basis of the analogy with the judge and the prisoner. You shall grant me that the meaning of an error admits of no doubt when the subject of the analysis acknowledges it himself. I, in turn, will admit that a direct proof for the suspected meaning cannot be obtained if the subject refuses us the information, and, of course, this applies also when the subject is not present to give us the information. As also in legal proceedings, we are then thrown back upon indications in order to form a decision, the truth of which is sometimes more and sometimes less probable. At law, for practical reasons, guilt has to be declared also on circumstantial evidence. There is no such necessity here; but neither are we bound to refrain from considering such evidence. It is a mistake to believe that a science consists in nothing but conclusively proved propositions, and it is unjust to demand that it should. It is a demand only made by those who feel a craving for authority in some form and a need to replace the religious catechism by something else, even if it be a scientific one. Science in its catechism has but few apodictic precepts; it consists mainly of statements which it has developed to varying degrees of probability. The capacity to be content with these approximations to certainty and the ability to carry on constructive work despite the lack of final confirmation are actually a mark of the scientific habit of mind.

But where shall we find a starting-point for our interpretations, and the indications for our proof, in cases where the subject under anal-

ysis says nothing to explain the meaning of the error? From various sources. First, by analogy with similar phenomena not produced by error, as when we maintain that the distortion of a name by mistake has the same intention to ridicule behind it as intentional distortion of names. And then, from the mental situation in which the error arose, from our knowledge of the character of the person who commits it, and of the feelings active in him before the error, to which it may be a response. As a rule, what happens is that we find the meaning of the error according to general principles; and this, to begin with, is only a conjecture, a tentative solution, proof being discovered later by an examination of the mental situation. Sometimes it is necessary to await further developments, which have been so to speak, foreshadowed by the error, before we can find confirmation of our conjecture.

I cannot easily give you evidence of this if I have to limit myself to the field of slips of the tongue, although even here I have a few good examples. The young man who offered to "in-sort" the lady is in fact very shy; the lady whose husband may eat and drink what *she* likes I know to be one of those managing women who rule the household with a rod of iron. Or take the following case: At a general meeting of a club a young member made a violent attack in a speech, in the course of which he spoke of the officers of the society as "*Lenders of the Committee*," which appears to be a substitute for *Members of the Committee*.<sup>1</sup> We should conjecture that against his attack some interfering tendency was active which was itself in some way connected with the idea of *lending*. As a matter of fact, an informant tells us that the speaker is in constant money difficulties and was actually attempting to raise money at the time. So the interfering tendency really is to be translated into the thought: "Be more moderate in your opposition: these are the people whom you want to lend you money."

If I diverge into the field of other kinds of errors I can give you a wide selection of examples of such circumstantial evidence.

If anyone forgets an otherwise familiar proper name and has difficulty in retaining it in his memory—even with an effort—it is not hard to guess that he has something against the owner of the name and does not like to think of him; consider in the light of this the following notes on the mental situation in which an error of this kind was made.

A Mr. Y fell in love with a lady, who did not return the feeling and shortly after married a Mr. X. Although Mr. Y had already known Mr. X for some time, and even had business relations with him, he forgets his name over and over again, so that he frequently has to ask someone the man's name when it is necessary to write to him.<sup>2</sup> Obviously Mr. Y wants to obliterate all knowledge of his fortunate rival. "Never thought of shall he be."

Another example: a lady inquires of a doctor about a common acquaintance, calling her by her maiden name. She has forgotten the married name. She admits that she strongly objected to the marriage and dislikes the husband intensely.<sup>3</sup>

Later we shall have much to say in other connections in regard to the forgetting of names; at the moment we are chiefly interested in the *mental situation* in which the lapse of memory occurs.

The forgetting of resolutions can in general be referred to an opposing current of feeling which is against carrying out the intention. It is not only we psycho-analysts who hold this view, however; it is the ordinary attitude of everyone in their daily affairs, which they only deny in theory. The protégé whose patron apologizes for having forgotten his request is not pacified by such an apology. He thinks immediately: "It's evidently nothing to him; he promised, but he doesn't mean to do it." Forgetting is therefore criticized even in life, in certain connections, and the difference between the popular and the psycho-analytic conception of these errors seems to be dispelled. Imagine a hostess receiving a guest with the words: "What, is it today you were coming? I quite forgot that I had asked you for to-day"; or a young man confessing to his beloved that he had forgotten all about the appointment they had arranged on the last occasion. He will never admit it; he will rather invent on the spur of the moment the most wildly improbable hindrances which prevented his coming and made it impossible for him to communicate with her from that day to this. We all know that in military service the excuse of having forgotten is worthless and saves no one from punishment; the system is recognized as justifiable. Here everyone is suddenly agreed that a certain mistake has a meaning and what that meaning is. Why are they not consistent enough to extend their insight to other errors and then

<sup>2</sup> From C. G. Jung.

<sup>3</sup> From A. A. Brill.

<sup>1</sup> *Vorschussmitglieder* instead of *Ausschussmitglieder*.

openly acknowledge it? There is naturally also an answer to this.

If the meaning of forgetting resolutions is so little open to doubt in the minds of people in general you will be the less surprised to find that writers employ such mistakes in a similar sense. Those of you who have seen or read Shaw's *Cæsar and Cleopatra* will recall that Cæsar, when departing in the last scene, is pursued by the feeling that there was something else he intended to do which he had now forgotten. At last it turns out what it is: to say farewell to Cleopatra. By this small device the author attempts to ascribe to the great Cæsar a feeling of superiority which he did not possess and to which he did not at all aspire. You can learn from historical sources that Cæsar arranged for Cleopatra to follow him to Rome and that she was living there with her little Cæsarion when Cæsar was murdered, whereupon she fled the city.

The cases of forgetting resolutions are as a rule so clear that they are of little use for our purpose, which is to discover in the mental situation indications of the meaning of the error. Let us turn, therefore, to a particularly ambiguous and obscure form of error, that of losing and mislaying objects. It will certainly seem incredible to you that the person himself could have any purpose in losing things, which is often such a painful accident. But there are innumerable instances of this kind: A young man loses a pencil to which he was much attached. A few days before he had had a letter from his brother-in-law which concluded with these words: "I have neither time nor inclination at present to encourage you in your frivolity and idleness."<sup>1</sup> Now the pencil was a present from this brother-in-law. Had it not been for this coincidence we could not of course have maintained that the loss involved any intention to get rid of the gift. Similar cases are very numerous. One loses objects when one has quarrelled with the giver and no longer wants to be reminded of him, or again, when one has tired of them and wants an excuse to provide oneself with something different and better. Dropping, breaking, and destroying things of course serve a similar purpose in regard to the object. Can it be considered accidental when, just before his birthday, a child loses and damages his possessions, for instance, his watch and his schoolbag?

Anyone who has experienced often enough the annoyance of not being able to find some-

thing which he has himself put away will certainly be unwilling to believe that he could have had any intention in so doing. And yet cases are not at all rare in which the circumstances attendant on the act of mislaying point to a tendency to put the object aside temporarily or permanently. Perhaps the best example of this kind is the following.

A young man told me this story: "A few years ago there were misunderstandings between me and my wife; I thought her too cold, and, though I willingly acknowledged her excellent qualities, we lived together without affection. One day, on coming in from a walk, she brought me a book which she had bought me because she thought it would interest me. I thanked her for her little attention, promised to read the book, put it among my things and never could find it again. Months passed by and occasionally I thought of this derelict book and tried in vain to find it. About six months later my dear mother, who lived some distance away, fell ill. My wife left our house to go and nurse her mother-in-law, who became seriously ill, giving my wife an opportunity of showing her best qualities. One evening I came home full of enthusiasm and gratitude towards my wife. I walked up to my writing desk and opened a certain drawer in it, without a definite intention but with a kind of somnambulistic sureness, and there before me lay the lost book which I had so often looked for."

With the disappearance of the motive the inability to find the mislaid object also came to an end.

I could multiply this collection of examples indefinitely; but I will not do so now. In my *Psycho-pathology of Everyday Life* (first published in 1901) you will find plenty of examples for the study of errors.<sup>2</sup> All these examples demonstrate the same thing over and over again; they make it probable to you that mistakes have a meaning and they show you how the meaning can be guessed or confirmed from the attendant circumstances. I restrict myself rather to-day, because our intention here was limited to studying these phenomena with a view to obtaining an introduction to psycho-analysis. There are only two groups of occurrences into which I must still go, the accumulated and combined errors, and confirmation of our interpretations by subsequent events.

Accumulated and combined errors are cer-

<sup>2</sup> Also in the writings of A. Maeder (*French*), A. A. Brill and Ernest Jones (*English*), and J. Stærcke (*Dutch*) and others.

<sup>1</sup> From B. Dattner.

tainly the finest flowers of the species. If we were only concerned to prove that errors had a meaning, we should have limited ourselves to them at the outset, for the meaning in them is unmistakable, even to the dullest intelligence, and strong enough to impress the most critical judgment. The repetition of the occurrences betrays a persistence which is hardly ever an attribute of chance, but which fits well with the idea of design. Further, the exchanging of one kind of mistake for another shows us what is the most important and essential element in the error; and that is, not its form, or the means of which it makes use, but the *tendency* which makes use of it and can achieve its end in the most various ways. Thus I will give you a case of repeated forgetting: Ernest Jones relates that he once allowed a letter to lie on his writing desk for several days for some unknown reason. At last he decided to post it, but received it back from the dead letter office, for he had forgotten to address it. After he had addressed it he took it to post but this time without a stamp. At this point he finally had to admit to himself his objection to sending the letter at all.

In another case, taking up a thing by mistake is combined with mislaying it. A lady travelled to Rome with her brother-in-law, a famous artist. The visitor was much fêted by the Germans living in Rome and received, among other things, a present of an antique gold medal. The lady was vexed because her brother-in-law did not appreciate the fine specimen highly enough. After her sister had arrived she returned home and discovered, upon unpacking, that she had brought the medal with her—how, she did not know. She wrote at once to her brother-in-law telling him that she would send the stolen property back to him the next day. But the next day the medal was so cleverly mislaid that it could not be discovered and could not be returned, and then it began to dawn upon the lady what her *absent-mindedness* had meant, namely, that she wanted to keep the work of art for herself.<sup>1</sup>

I have already given you an example of a combination of forgetfulness with an error, in the case in which someone forgets an appointment, and a second time, with the firm intention of not forgetting it again, appears at an hour which is not the appointed one. A quite analogous case was told me from his own experience by a friend who pursues literary as well as scientific interests. He said: "Some years

ago I accepted election to the Council of a certain literary society because I hoped that the society might at some time be useful to me in getting a play of mine produced; and, although not much interested, I attended the meetings regularly every Friday. A few months ago I received an assurance that my play would be produced at a theatre in F and since then it has invariably happened that I *forget* to attend the meetings of the society. When I read your writings on this subject, I reproached myself with my meanness in staying away now that these people can no longer be of use to me and determined on no account to forget on the following Friday. I kept reminding myself of my resolution until I carried it out and stood at the door of the meeting-room. To my amazement it was closed and the meeting was already over! I had made a mistake in the day of the week and it was then Saturday!"

It would be tempting to collect more of these examples, but I will pass on and, instead, let you glance at those cases in which interpretation has to wait for confirmation in the future.

The main condition in these cases is, as we might expect, that the mental situation at the time is unknown or cannot be ascertained. At the moment, therefore, our interpretation is no more than a supposition to which we ourselves would not ascribe too much weight. Later, however, something happens which shows us how well justified our previous interpretation was. I was once the guest of a young married couple and heard the young wife laughingly describe her latest experience, how the day after the return from the honeymoon she had called for her sister and gone shopping with her as in former times, while her husband went to his business. Suddenly she noticed a man on the other side of the street and, nudging her sister, said, "Look, there goes Mr. K." She had forgotten that this man had been her husband for some weeks. A shudder went over me as I heard the story, but I dared not draw the inference. Several years later the little incident came back to my mind after this marriage had come to a most unhappy end.

Maeder tells a story of a lady who had forgotten to try on her wedding-dress the day before the wedding, to the despair of the dress-maker, and remembered it only late in the evening. He connects it with the fact that soon after the marriage she was divorced by her husband. I know a woman now divorced from her husband who, in managing her money-affairs, frequently signed documents with her maiden

<sup>1</sup> From R. Reitler.

name, many years before she really resumed it. I know of other women who lost their wedding-rings on the honeymoon and I know, too, that the course of the marriage lent meaning to this accident. And now one striking example more, with a better ending. It is told of a famous German chemist that his marriage never took place because he forgot the hour of the ceremony and went to the laboratory instead of to the church. He was wise enough to let the matter rest with one attempt, and died unmarried at a ripe age.

Perhaps the idea has also come to you that in these examples mistakes seem to have replaced the omens or portents of the ancients. And indeed, certain kinds of portents were nothing but errors, for instance, when anyone stumbled or fell down. It is true that another group of omens bore the character of objective events rather than of subjective acts. But you would not believe how difficult it is sometimes to decide whether a specific instance belongs to the first category or to the second. The act knows so often how to disguise itself as a passive experience.

Every one of us who can look back over a fairly long experience of life would probably say that he might have spared himself many disappointments and painful surprises, if he had had the courage and resolution to interpret as omens the little mistakes which he noticed in his intercourse with others, and to regard them as signs of tendencies still in the background. For the most part one does not dare to do this; one has an impression that one would become superstitious again by a circuitous scientific path. And then, not all omens come true, and our theories will show you how it is that they need not all come true.

#### FOURTH LECTURE

##### THE PSYCHOLOGY OF ERRORS (*Conclusion*)

THAT errors have a meaning we may certainly set down as established by our efforts up to this point, and may take this conclusion as a basis for our further investigations. Let me once more emphasize the fact that we do not maintain—and for our purposes do not need to maintain—that every single mistake which occurs has a meaning, although I think that probable. It is enough for us to prove that such a meaning is relatively frequent in the various forms of errors. In this respect, by the way, the various forms show certain differences. Some cases of slips of the tongue, slips of the pen,

and so on, may be the effect of a purely physiological cause, though I cannot believe this possible of those errors which depend upon forgetfulness (forgetting of names or intentions, mislaying, and so on); losing possessions is in all probability to be recognized as unintentional in some cases; altogether our conceptions are only to a certain extent applicable to the mistakes which occur in daily life. These limitations should be borne in mind by you when we proceed on the assumption that errors are mental acts arising from the mutual interference of two intentions.

This is the first result of our psycho-analysis. Hitherto psychology has known nothing of such interferences or of the possibility that they could occasion manifestations of this kind. We have widened the domain of mental phenomena to a very considerable extent and have won for psychology phenomena which were never before accredited to it.

Let us dwell for a moment on the proposition that errors are *mental acts*. Does this mean any more than our former statement, that they have a meaning? I do not think so; on the contrary, it is a more indefinite statement and one more open to misunderstanding. Everything that can be observed in mental life will be designated at one time or another as a mental phenomenon. It depends, however, whether the particular mental phenomenon is directly due to bodily, organic or material agencies, in which case it does not fall to psychology for investigation; or whether it arose directly from other mental processes, behind which at some point the succession of organic agencies then begins. We have in mind the latter state of things when we describe a phenomenon as a mental process, and it is therefore more expedient to put our statement in this form: The phenomenon has meaning; and by meaning we understand significance, intention, tendency and a position in a sequence of mental concatenations.

There is another group of occurrences which is very closely related to errors but for which this name is not suitable. We call them *accidental* and *symptomatic acts*. They also appear to be unmotivated, insignificant and unimportant but, in addition to this, they have very clearly the feature of superfluity. They are, on the one hand, distinguishable from errors by the absence of any second intention to which they are opposed and which they disturb; on the other hand, they merge without any definite line of demarcation into the gestures and movements which we regard as expressions of the

emotions. To this class of accidental performances belong all those apparently purposeless acts which we carry out, as though in play, with clothing, parts of the body, objects within reach; also the omission of such acts; and again the tunes which we hum to ourselves. I maintain that all such performances have meaning and are explicable in the same way as are errors, that they are slight indications of other more important mental processes, and are genuine mental acts. I propose, however, not to linger over this further extension of the field of mental phenomena, but to return to the errors; for by a consideration of them problems of importance in the enquiry into psycho-analysis can be worked out much more clearly.

Undoubtedly, the most interesting questions which we formulated while considering errors, and have not yet answered, are the following: We said that errors result from the mutual interference of two different intentions, of which one may be called the intention interfered with, and the other the interfering tendency. The intentions interfered with give rise to no further questions, but concerning the others we wish to know, first, what kind of intentions these are that arise as disturbers of others, and secondly, what are the relations between the interfering tendencies and those which suffer the interference?

Allow me to take slips of the tongue again as representative of the whole series, and to answer the second question before the first.

The interfering tendency in the slip of the tongue may be connected in meaning with the intention interfered with, in which case the former contains a contradiction of the latter, or corrects, or supplements it. Or, in other more obscure and more interesting cases, the interfering tendency may have no connection whatever in meaning with the intention interfered with.

Evidence for the first of these two relationships can be found without difficulty in the examples already studied and in others similar to them. In almost all cases of slips of the tongue where the opposite of what is meant is said the interfering tendency expresses the opposite meaning to that of the intention interfered with, and the slip is the expression of the conflict between two incompatible impulses. "I declare the meeting open, but would prefer to have closed it" is the meaning of the President's slip. A political paper which had been accused of corruption defends itself in an article meant to culminate in the words: "Our readers will

testify that we have always laboured for the public benefit in the most *disinterested* manner." But the editor entrusted with the composition of the defence wrote "in the most *interested* manner." That is to say, he thinks, "I have to write this stuff, but I know better." A representative of the people, urging that the Kaiser should be told the truth *rückhaltslos* (unreservedly) hears an inner voice terrified at his boldness, and by a slip of the tongue transforms *rückhaltslos* into *rückgratslos* (without backbone, ineffectually).

In the examples already given, which produce an impression of contraction and abbreviation, the process represents a correction, addition, or continuation, in which a second tendency manifests itself alongside the first. "Things were then revealed, but better say it straight out, they were filthy, therefore—things were then *refilled*." "The people who understand this subject may be counted on the fingers of one hand, but no, there is really only one person who understands it, very well then—can be counted on *one finger*." Or, "my husband can eat and drink what he likes, but you know, *I* don't permit him to like this and that; so then—he may eat and drink what *I* like." In all these cases the slip arises from the content of the intention interfered with, or is directly connected with it.

The other kind of relationship between the two interfering tendencies seems strange. If the interfering tendency has nothing to do with the content of the one interfered with, whence comes it then, and how does it happen to make itself manifest just at that point? Observation, which alone can supply the answer to this, shows that the interfering tendency proceeds from a train of thought which has occupied the person shortly before and then reveals itself in this way as an after-effect, irrespective of whether or not it has already been expressed in speech. It is really therefore to be described as a perseveration, though not necessarily a perseveration of spoken words. An associative connection between the interfering tendency and that interfered with is not lacking here either, though it is not found in the content but is artificially established, sometimes with considerable *forcing* of the connections.

Here is a simple example of this which I observed myself. Once in the beautiful Dolomites I met two Viennese ladies who were starting for a walking-tour. I accompanied them part of the way and we discussed the pleasures, but also the trials, of this way of life. One of

the ladies admitted that spending the day like this entailed much discomfort. "It certainly is very unpleasant to tramp all day in the sun till one's blouse . . . and things are soaked through." In this sentence she had to overcome a slight hesitation at one point. Then she continued: "But then, when one gets *nach Hose* and can change . . ." (*Hose* means *drawers*: the lady meant to say *nach Hause* which means *home*). We did not analyse this slip, but I am sure you will easily understand it. The lady's intention had been to enumerate a more complete list of her clothes, "blouse, chemise and drawers." From motives of propriety, mention of the drawers (*Hose*) was omitted; but in the next sentence, the content of which is quite independent, the unuttered word came to light as a distortion of the word it resembled in sound, *home* (*Hause*).

Now we can turn at last to the main question which has been so long postponed, namely, what kind of tendencies these are which bring themselves to expression in this unusual way by interfering with other intentions. They are evidently very various, yet our aim is to find some element common to them all. If we examine a series of examples for this purpose we shall soon find that they fall into three groups. To the *first* group belong the cases in which the interfering tendency is known to the speaker and, moreover, was felt by him before the slip. Thus, in the case of the slip "refilled," the speaker not only admitted that he had criticized the events in question as "filthy," but further, that he had had the intention, which he subsequently reversed, of expressing this opinion in words. A *second* group is formed by other cases in which the interfering tendency is likewise recognized by the speaker as his own, but he is not aware that it was active in him before the slip. He therefore accepts our interpretation, but remains to some extent surprised by it. Examples of this attitude are probably more easily found in other errors than in slips of the tongue. In the *third* group the interpretation of the interfering tendency is energetically repudiated by the speaker; not only does he dispute that it was active in him before the slip, but he will maintain that it is altogether entirely alien to him. Recall the case about hiccupping and the positively discourteous rebuff which I brought upon myself by detecting the interfering tendency. You know that in our attitude towards these cases you and I are still far from an agreement. I should make nothing of the after-dinner speaker's de-

nial and hold fast to my interpretation unwaveringly, while you, I imagine, are still impressed by his vehemence and are wondering whether one should not forego the interpretation of such errors and let them pass for purely physiological acts, as in the days before analysis. I can imagine what it is that alarms you. My interpretation includes the assumption that tendencies of which a speaker knows nothing can express themselves through him and that I can deduce them from various indications. You hesitate before a conclusion so novel and so pregnant with consequences. I understand that, and admit that up to a point you are justified. But let one thing be clear: if you intend to carry to its logical conclusion the conception of errors which has been confirmed by so many examples, you must decide to make this startling assumption. If you cannot do this, you will have to abandon again the understanding of errors which you had only just begun to obtain.

Let us pause a moment on that which unites the three groups and is common to the three mechanisms of a slip of the tongue. Fortunately this common element is unmistakable. In the first two groups the interfering tendency is admitted by the speaker; in the first, there is the additional fact that it showed itself immediately before the slip. But in both cases *it has been forced back. The speaker had determined not to convert the idea into speech and then it happens that he makes a slip of the tongue; that is to say, the tendency which is debarred from expression asserts itself against his will and gains utterance, either by altering the expression of the intention permitted by him, or by mingling with it, or actually by setting itself in place of it.* This then is the mechanism of a slip of the tongue.

For my own part I can bring the process in the third group also into perfect harmony with the mechanism here described. I need only assume that these three groups are differentiated by the varying degrees to which the forcing back of an intention is effective. In the first group, the intention is present and makes itself perceptible before the words are spoken; not until then does it suffer the rejection for which it indemnifies itself in the slip. In the second group the rejection reaches further back; the intention is no longer perceptible even before the speech. It is remarkable that this does not hinder it in the least from being the active cause of the slip. But this state of things simplifies the explanation of the process in the third

group. I shall be bold enough to assume that a tendency can still express itself by an error though it has been debarred from expression for a long time, perhaps for a very long time, has not made itself perceptible at all, and can therefore be directly repudiated by the speaker. But leaving aside the problem of the third group, you must conclude from the other cases that a *suppression (Unterdrückung) of a previous intention to say something is the indispensable condition for the occurrence of a slip of the tongue.*

We may now claim to have made further progress in the understanding of errors. We not only know them to be mental phenomena in which meaning and purpose are recognizable, not only know that they arise from the mutual interference of two different intentions, but in addition we know that, for one of these intentions to be able to express itself by interfering with another, it must itself have been subject to some hindrance against its operation. It must first be itself interfered with, before it can interfere with others. Naturally this does not give us a complete explanation of the phenomena which we call errors. We see at once further questions arising, and in general we suspect that as we progress towards comprehension the more numerous will be the occasions for new questions. We might ask, for instance, why the matter does not proceed much more simply. If the intention to restrain a certain tendency instead of carrying it into effect is present in the mind, then this restraint ought to succeed, so that nothing whatever of the tendency gains expression, or else it might fail so that the restrained tendency achieves full expression. But errors are *compromise-formations*; they express part-success and part-failure for each of the two intentions; the threatened intention is neither entirely suppressed nor, apart from some instances, does it force itself through intact. We can imagine that special conditions must be present for the occurrence of such interference (or compromise)-formations, but we cannot even conjecture of what kind they may be. Nor do I think that we could discover these unknown circumstances by penetrating further into the study of errors. It will be necessary first to examine thoroughly yet other obscure fields of mental life: only the analogies to be met with there can give us courage to form those assumptions which are requisite for a more searching elucidation of errors. And one other point! To work from slight indications, as we constantly do in this

field, is not without its dangers. There is a mental disorder called *combinatory paranoia* in which the practice of utilizing such small indications is carried beyond all limits, and I naturally do not contend that the conclusions which are built up on such a basis are throughout correct. Only by the breadth of our observations, by the accumulation of similar impressions from the most varied forms of mental life, can we guard against this danger.

So now we will leave the analysis of errors. But there is one thing more which I might impress upon you: to keep in mind, as a model, the method by which we have studied these phenomena. You can perceive from these examples what the aim of our psychology is. Our purpose is not merely to describe and classify the phenomena, but to conceive them as brought about by the play of forces in the mind, as expressions of tendencies striving towards a goal, which work together or against one another. We are endeavouring to attain a *dynamic conception* of mental phenomena. In this conception, the trends we merely infer are more prominent than the phenomena we perceive.

So we will probe no further into errors; but we may still take a fleeting glimpse over the breadth of this whole field, in the course of which we shall both meet with things already known and come upon the tracks of others that are new. In so doing, we will keep to the division into three groups made at the beginning of our study: slips of the tongue, with the co-ordinate forms of slips of the pen, misreading, mis-hearing; of forgetting with its subdivisions according to the object forgotten (proper names, foreign words, resolutions, impressions); and of mislaying, mistaking, and losing objects. Mistakes, in so far as they concern us, are to be grouped partly under the head of forgetting, partly under acts erroneously performed (picking up the wrong objects, etc.).

We have already treated slips of the tongue in great detail yet there is still something to add. There are certain small affective manifestations related to slips of the tongue which are not entirely without interest. No one likes to think he has made a slip of the tongue; one often fails to hear it when made by oneself, but never when made by someone else. Slips of the tongue are in a certain sense infectious; it is not at all easy to speak of them without making them oneself. It is not hard to detect the motivation of even the most trifling forms of them, although these do not throw any particular light on hidden mental processes. If, for

instance, anyone pronounces a long vowel as a short one, in consequence of a disturbance over the word, no matter how motivated, he will as a result soon after lengthen a short vowel and commit a new slip in compensation for the first. The same thing occurs if anyone pronounces a diphthong indistinctly and carelessly, for instance, "ew" or "oy" as "i"; he tries to correct it by changing a subsequent "i" into "ew" or "oy." Some consideration relating to the hearer seems to be behind this behaviour, as though he were not to be allowed to think that the speaker is indifferent how he treats his mother-tongue. The second, compensating distortion actually has the purpose of drawing the hearer's attention to the first and assuring him that it has not escaped the speaker either. The most frequent, insignificant, and simple forms of slips consist in contractions and anticipations in inconspicuous parts of the speech. In a long sentence, for instance, slips of the tongue would be of the kind in which the last word intended influences the sound of an earlier word. This gives an impression of a certain impatience to be done with the sentence, and in general it points to a certain resistance against the communication of this sentence, or the speech altogether. From this we come to border-line cases, in which the differences between the psycho-analytical and the ordinary physiological conception of slips of the tongue become merged. We assume that in these cases a disturbing tendency is opposing the intended speech; but it can only betray its presence and not what its own purpose is. The interference which it causes follows some sound-influence or associative connection and may be regarded as a distraction of attention away from the intended speech. But neither in this distraction of attention, nor in the associative tendency which has been activated, lies the essence of the occurrence; the essence lies rather in the hint the occurrence gives of the presence of some other intention interfering with the intended speech, the nature of which cannot in this case be discovered from its effects, as is possible in all the more pronounced cases of slips of the tongue.

Slips of the pen, to which I now turn, are so like slips of the tongue in their mechanism that no new points of view are to be expected from them. Perhaps a small addition to our knowledge from this group will content us. Those very common little slips of the pen, contractions, anticipations of later words, particularly of the last words, point to a general distaste for writing and to an impatience to be done;

more pronounced effects in slips of the pen allow the nature and intention of the interference to be recognized. In general, if one finds a slip of the pen in a letter one knows that the writer's mind was not working smoothly at the moment; what was the matter one cannot always establish. Slips of the pen are frequently as little noticed by those who make them as slips of the tongue. The following observation is striking in this connection. There are, of course, some persons who have the habit of always re-reading every letter they write before sending it. Others do not do this; but, if the latter make an exception and re-read a letter, they then always have an opportunity of finding and correcting a striking slip of the pen. How is this to be explained? It almost looks as if such people knew that they had made a slip in writing the letter. Are we really to believe that this is so?

There is an interesting problem connected with the practical significance of slips of the pen. You may recall the case of the murderer H who managed, by asserting himself to be a bacteriologist, to obtain cultures of highly dangerous disease-germs from scientific institutions, but used them for the purpose of doing away in this most modern fashion with people connected with him. This man once complained to the authorities of one of these institutions about the ineffectiveness of the cultures sent him, but committed a slip of the pen and, instead of the words "in my experiments on mice and guinea-pigs (*Mäusen und Meerschweinchen*)," the words "in my experiments on people (*Menschen*)" were plainly legible. This slip even attracted the attention of the doctors at the institute but, so far as I know, they drew no conclusion from it. Now, what do you think? Would it not have been better if the doctors had taken the slip of the pen as a confession and started an investigation so that the murderer's proceedings might have been arrested in time? In this case, does not ignorance of our conception of errors result in neglect which, in actuality, may be very important? Well, I know that such a slip of the pen would certainly rouse great suspicion in me; but there is an important objection against regarding it as a confession. The matter is not so simple. The slip of the pen is certainly an indication but, alone, it would not have justified an enquiry. It does indeed betray that the man is occupied with the thought of infecting human beings; but it does not show with certainty whether this thought is a definite plan to do harm or a

mere phantasy of no practical importance. It is even possible that a person making such a slip will deny, with the soundest subjective justification, the existence of such a phantasy in himself, and will reject the idea as a thing utterly alien to him. Later, when we come to consider the difference between psychical reality and material reality you will be better able to appreciate these possibilities. But this again is a case in which an error was found subsequently to have unsuspected significance.

Misreading brings us to a mental situation which is clearly different from that of slips of the tongue or the pen. One of the two conflicting tendencies is here replaced by a sensory excitation and is perhaps therefore less tenacious. What one is reading is not a product of one's own mind, as is that which one is going to write. In the large majority of cases, therefore, misreading consists in complete substitution. A different word is substituted for the word to be read, without there necessarily being any connection in the content between the text and the effect of the mistake, and usually by means of a resemblance between the words. Lichtenberg's example of this, *Agamemnon* instead of *angenommen*, is the best of this group. To discover the interfering tendency which causes the mistake one may put aside the original text altogether; the analytic investigation may begin with two questions: What is the first idea occurring in free association to the effect of the misreading (the substitute), and in what circumstances did the misreading occur? Occasionally a knowledge of the latter is sufficient in itself to explain the misreading, as, for instance, when someone wandering about a strange town, driven by urgent needs, reads the word *Closethaus* on a large sign on the first storey. He has just time to wonder that the board has been fixed at that height when he discovers that the word on it is actually *Corsethaus*. In other cases where there is a lack of connection in content between the text and the slip a thorough analysis is necessary, which cannot be accomplished without practice in psycho-analytic technique and confidence in it. But it is not usually so difficult to come by the explanation of a case of misreading. In the example *Agamemnon*, the substituted word betrays without further difficulty the line of thought from which the disturbance arose. In this time of war, for instance, it is very common for one to read everywhere names of towns, generals, and military expressions, which are continually in one's ears, wherever

one sees a word at all resembling them. Whatever interests and occupies the mind takes the place of what is alien and as yet uninteresting. The shadows of thoughts in the mind dim the new perceptions.

Another kind of misreading is possible, in which the text itself arouses the disturbing tendency, whereupon it is usually changed into its opposite. Someone is required to read something which he dislikes, and analysis convinces him that a strong wish to reject what is read is responsible for the alteration.

In the first-mentioned, more frequent cases of misreading two factors to which we ascribed great importance in the mechanism of errors are inconspicuous; these are the conflict between two tendencies and the forcing back of one of them which compensates itself by producing the error. Not that anything contradictory of this occurs in misreading, but nevertheless the importunity of the train of thought tending to the mistake is far more conspicuous than the restraint which it may have previously undergone. Just these two factors are most clearly observable in the different situations in which errors occur through forgetfulness.

The forgetting of resolutions has positively but one meaning; the interpretation of it, as we have heard, is not denied even by the layman. The tendency interfering with the resolution is always an opposing one, an unwillingness, concerning which it only remains to enquire why it does not come to expression in a different and less disguised form; for the existence of this opposing tendency is beyond doubt. Sometimes it is possible, too, to infer something of the motives which necessitate the concealment of this antipathy; one sees that it would certainly have been condemned if it declared its opposition openly, whereas by craft, in the error, it always achieves its end. When an important change in the mental situation occurs between the formation of the resolution and its execution, in consequence of which the execution would no longer be required, then if it were forgotten the occurrence could no longer come within the category of errors. There would be nothing to wonder at in the error, for one recognizes that it would have been superfluous to remember the resolution; it had been either permanently or temporarily cancelled. Forgetting to carry out a resolution can only be called an error when there is no reason to believe that any such cancellation has occurred.

Cases of forgetting to carry out resolutions are usually so uniform and transparent, that

they are of no interest for our researches. There are two points, nevertheless, at which something new can be learnt by studying this type of error. We have said that forgetting and not executing a resolution indicate an antagonistic tendency in opposition to it. This is certainly true, but our own investigations show that this *counter-will* may be of two kinds, either immediate or mediate. What is meant by the latter is best explained by one or two examples. When the patron forgets to say a good word for his protégé to some third person, it may happen because he is actually not much interested in the protégé and therefore has no great inclination to do it. This, in any case, will be the protégé's view of the patron's omission. But the matter may be more complicated. The antipathy against executing the resolution may come from some other source in the patron and be directed to some other point. It need have nothing at all to do with the protégé, but is perhaps directed against the third person to whom the recommendation was to be made. Here again, you see, what objections there are against applying our interpretations practically. In spite of having correctly interpreted the error, the protégé is in danger of becoming too suspicious and of doing his patron a grave injustice. Again, if someone forgets an appointment which he had promised and was resolved to attend, the commonest cause is certainly a direct disinclination to meet the other person. But analysis might produce evidence that the interfering tendency was concerned, not with the person, but with the place of meeting, which was avoided on account of some painful memory associated with it. Or if one forgets to post a letter the opposing tendency may be concerned with the contents of the letter; but this does not exclude the possibility that the letter in itself is harmless and becomes the subject of a counter-tendency only because something in it reminds the writer of another letter, written previously, which did in fact afford a direct basis for antipathy. It may then be said that the antipathy has been *transferred* from the earlier letter, where it was justified, to the present one where it actually has no object. So you see that restraint and caution must be exercised in applying our quite well-founded interpretations; that which is psychologically equivalent may in actuality have many meanings.

That such things should be must seem very strange to you. Perhaps you will be inclined to assume that the *indirect* counter-will is enough

to characterize the incident as pathological. But I can assure you that it is also found within the boundaries of health and normality. And further, do not misunderstand me; this is in no sense a confession on my part that our analytic interpretations are not to be relied on. I have said that forgetting to execute a plan may bear many meanings, but this is so only in those cases where no analysis is undertaken and which we have to interpret according to our general principles. If an analysis of the person in the case is carried out it can always be established with sufficient certainty whether the antipathy is a direct one, or what its source is otherwise.

The following is a second point: when we find proof in a large majority of cases that the forgetting of an intention proceeds from a counter-will, we gain courage to extend this solution to another group of cases in which the person analysed does not confirm, but denies, the presence of the counter-will inferred by us. Take as an example of this such exceedingly frequent occurrences as forgetting to return borrowed books or to pay bills or debts. We will be so bold as to suggest, to the person in question, that there is an intention in his mind of keeping the books and not paying the debts, whereupon he will deny this intention but will not be able to give us any other explanation of his conduct. We then insist that he has this intention but is not aware of it; it is enough for us, though, that it betrays itself by the effect of the forgetting. He may then repeat that he had merely forgotten about it. You will recognize the situation as one in which we have already been placed once before. If we intend to carry through, to their logical conclusions, the interpretations of errors which have been proved justified in so many cases, we shall be unavoidably impelled to the assumption that tendencies exist in human beings which can effect results without their knowing of them. With this, however, we place ourselves in opposition to all views prevailing in life and in psychology.

Forgetting proper names, and foreign names and words, can be traced in the same way to a counter-tendency aiming either directly or indirectly against the name in question. I have already given you several examples of such direct antipathy. Indirect causation is particularly frequent here and careful analysis is generally required to elucidate it. Thus, for instance, in the present time of war which forces us to forego so many of our former pleasures, our ability to recall proper names suffers severely

by connections of the most far-fetched kind. It happened to me lately to be unable to remember the name of the harmless Moravian town of Bisenz; and analysis showed that I was guilty of no direct antagonism in the matter, but that the resemblance to the name of the Palazzo Bisenzi in Orvieto, where I had spent many happy times in the past, was responsible. As a motive of the tendency opposing the recollection of this name, we here for the first time encounter a principle which will later on reveal itself to be of quite prodigious importance in the causation of neurotic symptoms: namely, the aversion on the part of memory against recalling anything connected with painful feelings that would revive the pain if it were recalled. In this tendency towards *avoidance of pain* from recollection or other mental processes, this flight of the mind from that which is unpleasant, we may perceive the ultimate purpose at work behind not merely the forgetting of names, but also many other errors, omissions, and mistakes.

The forgetting of names seems, however, to be especially facilitated psycho-physiologically, and therefore does occur on occasions where the intervention of an unpleasantness-motive cannot be established. When anyone has a tendency to forget names, it can be confirmed by analytic investigation that names escape, not merely because he does not like them or because they remind him of something disagreeable, but also because the particular name belongs to some other chain of associations of a more intimate nature. The name is anchored there, as it were, and is refused to the other associations activated at the moment. If you recall the devices of memory systems you will realize with some surprise that the same associations which are there artificially introduced, in order to save names from being forgotten, are also responsible for their being forgotten. The most conspicuous example of this is afforded by proper names of persons, which naturally possess quite different values for different people. For instance, take a first name, such as Theodore. For some of you it will have no particular significance; for others it will be the name of father, brother, friend, or your own name. Analytic experience will show you that the former among you will be in no danger of forgetting that some stranger bears this name; whereas the latter will be continually inclined to grudge to strangers a name which to them seems reserved for an intimate relationship. Now let us assume that this inhibition due to

associations may coincide with the operation of the "pain"-principle, and in addition with an indirect mechanism; you will then be able to form a commensurate idea of the complexity, in causation, of such temporary forgetting of names. An adequate analysis that does justice to the facts will, however, completely disclose all these complications.

The forgetting of impressions and experiences shows the working of the tendency to ward off from memory that which is unpleasant much more clearly and invariably than the forgetting of names. It does not of course belong in its entirety to the category of errors, but only in so far as it appears to us remarkable and unjustified, judged by the standard of general experience; as, for instance, where recent or important impressions are forgotten, or where one memory is forgotten out of an otherwise well-remembered sequence. How and why we have the capacity of forgetting in general, particularly how we are able to forget experiences which have certainly left the deepest impression on us, such as the events of our childhood, is quite a different problem, in which the defence against painful associations plays a certain part but is far from explaining everything. That unwelcome impressions are easily forgotten is an indubitable fact. Various psychologists have remarked it; and the great Darwin was so well aware of it that he made a golden rule for himself of writing down with particular care observations which seemed unfavourable to his theory, having become convinced that just these would be inclined to slip out of recollection.

Those who hear for the first time of this principle of defence against unpleasant memory by forgetfulness seldom fail to raise the objection that, on the contrary, in their experience it is just that which is painful which it is hard to forget, since it always comes back to mind to torture the person against his will—as, for example, the recollection of grievances or humiliations. This fact is quite correct, but the objection is not sound. It is important to begin early to reckon with the fact that the mind is an arena, a sort of tumbling-ground, for the struggles of antagonistic impulses; or, to express it in non-dynamic terms, that the mind is made up of contradictions and pairs of opposites. Evidence of one particular tendency does not in the least preclude its opposite; there is room for both of them. The material questions are: How do these opposites stand to one another and what effects proceed from

one of them and what from the other?

Losing and mislaying objects is of especial interest on account of the numerous meanings it may have, and the multiplicity of the tendencies in the service of which these errors may be employed. What is common to all the cases is the wish to lose something; what varies in them is the reason for the wish and the aim of it. One loses something if it has become damaged; if one has an impulse to replace it with a better; if one has ceased to care for it; if it came from someone with whom unpleasantness has arisen; or if it was acquired in circumstances that one no longer wishes to think of. Letting things fall, spoiling, or breaking things, serves the same tendency. In social life it is said that unwelcome and illegitimate children are found to be far more often weakly than those conceived in happier circumstances. This result does not imply that the crude methods of the so-called baby-farmers have been employed; some degree of carelessness in the supervision of the child should be quite enough. The preservation, or otherwise, of objects may well follow the same lines as that of children.

Then too it may happen that a thing will become destined to be lost without its having shed any of its value—that is, when there is an impulse to sacrifice something to fate in order to avert some other dreaded loss. According to the findings of analysis, such conjurings of fate are still very common among us, so that our losses are often voluntary sacrifices. Losing may equally well serve the impulses of spite or of self-punishment; in short, the more remote forms of motivation behind the impulse to do away with something by losing cannot easily be exhausted.

Mistaking of objects, or erroneous performance of actions, like other errors, is often made use of to fulfil a wish which should be denied; the intention masquerades as a lucky chance. Thus, as once happened to a friend, one has to take a train, most unwillingly, in order to pay a visit in the suburbs and then, in changing trains at a connection, gets by mistake into one which is returning to town; or, on a journey someone might greatly like to make a halt at some stopping-place, which cannot be done owing to fixed engagements elsewhere, whereupon he mistakes or misses the connection, so that the desired delay is forced upon him. Or, as happened to one of my patients whom I had forbidden to telephone to the lady he was in love with, he *by mistake* and *thoughtlessly* gave

the wrong number when he meant to telephone to me, so that he was suddenly connected with her. The following account by an engineer is a pretty example of the conditions under which damage to material objects may be done, and also demonstrates the practical significance of directly faulty actions.

"Some time ago I worked with several colleagues in the laboratory of a High School on a series of complicated experiments in elasticity, a piece of work we had undertaken voluntarily; it was beginning to take up more time, however, than we had anticipated. One day, as I went into the laboratory with my friend F, he remarked how annoying it was to him to lose so much time today as he had so much to do at home; I could not help agreeing with him and said half-jokingly, referring to an occasion the week before: 'Let us hope the machine will break down again so that we can stop work and go home early.' In arranging the work it happened that F was given the regulation of the valve of the press; that is to say, he was, by cautiously opening the valve, to let the liquid pressure out of the accumulator slowly into the cylinder of the hydraulic press. The man who was conducting the experiment stood by the pressure gauge, and, when the right pressure was reached, called out loudly, 'Stop.' At this command F seized the valve and turned with all his might—to the left! (All valves without exception close to the right.) Thereby the whole pressure in the accumulator suddenly came into the press, a strain for which the connecting-pipes are not designed, so that one of them instantly burst—quite a harmless accident, but one which forced us, nevertheless, to cease work for the day and go home. It is characteristic, by the way, that not long after, when we were discussing the affair, my friend F had no recollection whatever of my remark, which I recalled with certainty."

So with this in mind you may begin to suspect that it is not always a mere chance which makes the hands of your servants such dangerous enemies to your household effects. And you may also raise the question whether it is always an accident when one injures oneself or exposes oneself to danger—ideas which you may put to the test by analysis when you have an opportunity.

This is far from being all that could be said about errors. There is still much to be enquired into and discussed. But I shall be satisfied if you have been shaken somewhat in your previous beliefs by our investigations, so far as

they have gone, and if you have gained a certain readiness to accept new ones. For the rest, I must be content to leave you with certain problems still unsolved. We cannot prove all our principles by the study of errors, nor are we indeed by any means solely dependent on this material. The great value of errors for our purpose lies in this, that they are such common occurrences, may easily be observed in oneself, and are not at all contingent upon illness. I should like to mention one more of your unanswered questions before concluding: "If,

as we see from so many examples, people come so close to understanding errors and so often act as if they perceived their meaning, how is it possible that they should so generally consider them accidental, senseless, and meaningless, and so energetically oppose the psycho-analytic explanation of them?"

You are right: this is indeed striking and requires an explanation. But I will not give it to you; I will rather guide you slowly towards the connections by which the explanation will be forced upon you without any aid from me.

## PART II. DREAMS

### FIFTH LECTURE

#### DIFFICULTIES AND PRELIMINARY APPROACH TO THE SUBJECT

ONE day the discovery was made that the symptoms of disease in certain nervous patients have meaning.<sup>1</sup> It was upon this discovery that the psycho-analytic method of treatment was based. In this treatment it happened that patients in speaking of their symptoms also mentioned their dreams, whereupon the suspicion arose that these dreams too had meaning.

However, we will not pursue this historical path, but will strike off in the opposite direction. Our aim is to demonstrate the meaning of dreams, in preparation for the study of the neuroses. There are good grounds for this reversal of procedure, since the study of dreams is not merely the best preparation for that of the neuroses, but a dream is itself a neurotic symptom and, moreover, one which possesses for us the incalculable advantage of occurring in all healthy people. Indeed, if all human beings were healthy and would only dream, we could gather almost all the knowledge from their dreams which we have gained from studying the neuroses.

So dreams become the object of psycho-analytic research—another of these ordinary, under-rated occurrences, apparently of no practical value, like *errors*, and sharing with them the characteristic of occurring in healthy

persons. But in other respects the conditions of work are rather less favourable. Errors had only been neglected by science, people had not troubled their heads much about them, but at least it was no disgrace to occupy oneself with them. True, people said, there are things more important but still something may possibly come of it. To occupy oneself with dreams, however, is not merely unpractical and superfluous, but positively scandalous: it carries with it the taint of the unscientific and arouses the suspicion of personal leanings towards mysticism. The idea of a medical student troubling himself about dreams when there is so much in neuropathology and psychiatry itself that is more serious—tumours as large as apples compressing the organ of the mind, hæmorrhages, chronic inflammatory conditions in which the alterations in the tissues can be demonstrated under the microscope! No, dreams are far too unworthy and trivial to be objects of scientific research.

There is yet another factor involved which, in itself, sets at defiance all the requirements of exact investigation. In investigating dreams even the object of research, the dream itself, is indefinite. A delusion, for example, presents clear and definite outlines. "I am the Emperor of China," says your patient plainly. But a dream? For the most part it cannot be related at all. When a man tells a dream, has he any guarantee that he has told it correctly, and not perhaps altered it in the telling or been forced to invent part of it on account of the vagueness of his recollection? Most dreams cannot be remembered at all and are forgotten except for

<sup>1</sup> By Joseph Breuer, in the years 1880-1882. Cf. my lectures on Psycho-Analysis, delivered in the United States in 1909 [*The Origin and Development of Psycho-Analysis*, see p. 1 above].

some tiny fragments. And is a scientific psychology or a method of treatment for the sick to be founded upon material such as this?

A certain element of exaggeration in a criticism may arouse our suspicions. The arguments brought against the dream as an object of scientific research are clearly extreme. We have met with the objection of triviality already in "errors," and have told ourselves that great things may be revealed even by small indications. As to the indistinctness of dreams, that is a characteristic like any other—we cannot dictate to things their characteristics; besides, there are also dreams which are clear and well-defined. Further, there are other objects of psychiatric investigation which suffer in the same way from the quality of indefiniteness, e.g. the obsessive ideas of many cases, with which nevertheless many psychiatrists of repute and standing have occupied themselves. I will recall the last case of the kind which came before me in medical practice. The patient, a woman, presented her case in these words: "I have a certain feeling, as if I had injured, or had meant to injure, some living creature—perhaps a child—no, no, a dog rather, as if perhaps I had pushed it off a bridge—or done something else." Any disadvantage resulting from the uncertain recollection of dreams may be remedied by deciding that exactly what the dreamer tells is to count as the dream, and by ignoring all that he may have forgotten or altered in the process of recollection. Finally, one cannot maintain in so sweeping a fashion that dreams are unimportant things. We know from our own experience that the mood in which we awake from a dream may last throughout the day, and cases have been observed by medical men in which mental disorder began with a dream, the delusion which had its source in this dream persisting; further, it is told of historical persons that impulses to momentous deeds sprang from their dreams. We may therefore ask: What is the real cause of the disdain in which dreams are held in scientific circles? In my opinion it is the reaction from the over-estimation of them in earlier times. It is well known that it is no easy matter to reconstruct the past, but we may assume with certainty (you will forgive my jest) that as early as three thousand years ago and more our ancestors dreamt in the same way as we do. So far as we know, all ancient peoples attached great significance to dreams and regarded them as of practical value; they obtained from them auguries of the future and

looked for portents in them. For the Greeks and other Orientals, it was at times as unthinkable to undertake a campaign without a dream-interpreter as it would be today without air-scouts for intelligence. When Alexander the Great set out on his campaign of conquest the most famous interpreters of dreams were in his following. The city of Tyre, still at that time on an island, offered so stout a resistance to the king that he entertained the idea of abandoning the siege; then one night he dreamed of a satyr dancing in triumph, and when he related this dream to his interpreters they informed him that it foretold his victory over the city; he gave the order to attack and took Tyre by storm. Among the Etruscans and Romans other methods of foretelling the future were employed, but during the whole of the Græco-Roman period the interpretation of dreams was practiced and held in high esteem. Of the literature on this subject the principal work at any rate has come down to us, namely, the book of Artemidorus of Daldis, who is said to have lived at the time of the Emperor Hadrian. How it happened that the art of dream-interpretation declined later and dreams fell into disrepute, I cannot tell you. The progress of learning cannot have had very much to do with it, for in the darkness of the middle ages things far more absurd than the ancient practice of the interpretation of dreams were faithfully retained. The fact remains that the interest in dreams gradually sank to the level of superstition and could hold its own only amongst the uneducated. In our day, there survive, as a final degradation of the art of dream-interpretation, the attempts to find out from dreams numbers destined to draw prizes in games of chance. On the other hand, exact science of the present day has repeatedly concerned itself with the dream, but always with the sole object of illustrating *physiological* theories. By medical men, naturally, a dream was never regarded as a mental process but as the mental expression of physical stimuli. Binz in 1876 pronounced the dream to be "a physical process, always useless and in many cases actually morbid, a process above which the conception of the world-soul and of immortality stands as high as does the blue sky above the most low-lying, weed-grown stretch of sand." Maury compares dreams with the spasmodic jerking of St. Vitus' dance, contrasted with the co-ordinated movements of the normal human being; in an old comparison a parallel is drawn between the content of a dream and

the sounds which would be produced if "some-one ignorant of music let his ten fingers wander over the keys of an instrument."

*Interpretation* means discovering a hidden meaning, but there can be no question of attempting this while such an attitude is maintained towards the dream-performance. Look up the description of dreams given in the writings of Wundt, Jodl and other recent philosophers: they are content with the bare enumeration of the divergences of the dream-life from waking thought with a view to depreciating the dreams: they emphasize the lack of connection in the associations, the suspended exercise of the critical faculty, the elimination of all knowledge, and other indications of diminished functioning. The single valuable contribution to our knowledge about dreams for which we are indebted to exact science relates to the influence upon the dream-content of physical stimuli operating during sleep. We have the work of a Norwegian author who died recently—J. Mourly Vold—two large volumes on experimental investigation of dreams (translated into German in 1910 and 1912), which are concerned almost entirely with the results obtained by change in the position of the limbs. These investigations have been held up to us as models of exact research in the subject of dreams. Now can you imagine what would be the comment of exact science on learning that we intend to try to find out the *meaning* of dreams? The comment that has perhaps been made already! However, we will not allow ourselves to be appalled at the thought. If it was possible for errors to have an underlying meaning, it is possible that dreams have one too; and errors have, in very many cases, a meaning which has eluded the researches of exact science. Let us adopt the assumption of the ancients and of simple folk, and follow in the footsteps of the dream-interpreters of old.

First of all, we must take our bearings in this enterprise and make a survey of the field of dreams. What exactly is a dream? It is difficult to define it in a single phrase. Yet we need not seek after a definition, when all we need is to refer to something familiar to everyone. Still we ought to pick out the essential features in dreams. How are we to discover these features? The boundaries of the region we are entering comprise such vast differences, differences whichever way we turn. That which we can show to be common to all dreams is probably what is essential.

Well then—the first common characteristic

of all dreams would be that we are asleep at the time. Obviously, the dream is the life of the mind during sleep, a life bearing certain resemblances to our waking life and, at the same time, differing from it widely. That, indeed, was Aristotle's definition. Perhaps dream and sleep stand in yet closer relationship to each other. We can be waked by a dream; we often have a dream when we wake spontaneously or when we are forcibly roused from sleep. Dreams seem thus to be an intermediate condition between sleeping and waking. Hence, our attention is directed to sleep itself: what then is sleep?

That is a physiological or biological problem concerning which much is still in dispute. We can come to no decisive answer, but I think we may attempt to define one psychological characteristic of sleep. Sleep is a condition in which I refuse to have anything to do with the outer world and have withdrawn my interest from it. I go to sleep by retreating from the outside world and warding off the stimuli proceeding from it. Again, when I am tired by that world I go to sleep. I say to it as I fall asleep: "Leave me in peace, for I want to sleep." The child says just the opposite: "I won't go to sleep yet; I'm not tired, I want more things to happen to me!" Thus the biological object of sleep seems to be recuperation, its psychological characteristic the suspension of interest in the outer world. Our relationship with the world which we entered so unwillingly seems to be endurable only with intermission; hence we withdraw again periodically into the condition prior to our entrance into the world: that is to say, into intra-uterine existence. At any rate, we try to bring about quite similar conditions—warmth, darkness and absence of stimulus—characteristic of that state. Some of us still roll ourselves tightly up into a ball resembling the intra-uterine position. It looks as if we grown-ups do not belong wholly to the world, but only by two-thirds; one third of us has never yet been born at all. Every time we wake in the morning it is as if we were newly born. We do, in fact, speak of the condition of waking from sleep in these very words: we feel "as if we were newly born,"—and in this we are probably quite mistaken in our idea of the general sensations of the new-born infant; it may be assumed on the contrary that it feels extremely uncomfortable. Again, in speaking of birth we speak of "seeing the light of day."

If this is the nature of sleep, then dreams do not come into its scheme at all, but seem rather

to be an unwelcome supplement to it; and we do indeed believe that dreamless sleep is the best, the only proper sleep. There should be no mental activity during sleep; if any such activity bestirs itself, then in so far have we failed to reach the true pre-natal condition of peace; we have not been able to avoid altogether some remnants of mental activity, and the act of dreaming would represent these remnants. In that event it really does seem that dreams do not need to have meaning. With errors it was different, for they were at least activities manifested in waking life; but if I sleep and have altogether suspended mental activity, with the exception of certain remnants which I have not been able to suppress, there is no necessity whatever that they should have any meaning. In fact, I cannot even make use of any such meaning, seeing that the rest of my mind is asleep. It can really then be a matter of spasmodic reactions only, of such mental phenomena only as have their origin in physical stimulation. Hence, dreams must be remnants of the mental activity of waking life disturbing sleep, and we might as well make up our minds forthwith to abandon a theme so unsuited to the purposes of psycho-analysis.

Superfluous as dreams may be, however, they do exist nevertheless, and we can try to account for their existence to ourselves. Why does not mental life go off to sleep? Probably because there is something that will not leave the mind in peace; stimuli are acting upon it and to these it is bound to react. Dreams therefore are the mode of reaction of the mind to stimuli acting upon it during sleep. We note here a possibility of access to comprehension of dreams. We can now endeavour to find out, in various dreams, what are the stimuli seeking to disturb sleep, the reaction to which takes the form of dreams. By doing this we should have worked out the first characteristic common to all dreams.

Is there any other common characteristic? Yes, there is another, unmistakable, and yet much harder to lay hold of and describe. The character of mental processes during sleep is quite different from that of waking processes. In dreams we go through many experiences, which we fully believe in, whereas in reality we are perhaps only experiencing the single disturbing stimulus. For the most part our experiences take the form of visual images; there may be feeling as well, thoughts, too, mixed up with them; and the other senses may be drawn in; but for the most part dreams consist

of visual images. Part of the difficulty of citing a dream comes from the fact that we have to translate these images into words. "I could draw it," the dreamer often says to us, "but I do not know how to put it into words." Now this is not exactly a diminution in the mental capacity, as seen in a contrast between a feeble-minded person and a man of genius. The difference is rather a qualitative one, but it is difficult to say precisely wherein it lies. G. T. Fechner once suggested that the stage whereon the drama of the dream (within the mind) is played out is other than that of the life of waking ideas. That is a saying which we really do not understand, nor do we know what it is meant to convey to us, but it does actually reproduce the impression of strangeness which most dreams make upon us. Again, the comparison of the act of dreaming with the performances of an unskilled hand in music breaks down here, for the piano will certainly respond with the same notes, though not with melodies, to a chance touch on its keys. We will keep this second common characteristic of dreams carefully in view, even though we may not understand it.

Are there any other qualities common to all dreams? I can think of none, but can see differences only, whichever way I look, differences too in every respect—in apparent duration, definiteness, the part played by affects, persistence in the mind, and so forth. This is really not what we should naturally expect in the case of a compulsive attempt, at once meagre and spasmodic, to ward off a stimulus. As regards the length of dreams, some are very short, containing only one image, or very few, or a single thought, possibly even a single word; others are peculiarly rich in content, enact entire romances and seem to last a very long time. There are dreams as distinct as actual experiences, so distinct that for some time after waking we do not realize that they were dreams at all; others, which are ineffably faint, shadowy and blurred; in one and the same dream, even, there may be some parts of extraordinary vividness alternating with others so indistinct as to be almost wholly elusive. Again, dreams may be quite consistent or at any rate coherent, or even witty or fantastically beautiful; others again are confused, apparently imbecile, absurd or often absolutely mad. There are dreams which leave us quite cold, others in which every affect makes itself felt—pain to the point of tears, terror so intense as to wake us, amazement, delight, and so on. Most

dreams are forgotten soon after waking; or they persist throughout the day, the recollection becoming fainter and more imperfect as the day goes on; others remain so vivid (as, for example, the dreams of childhood) that thirty years later we remember them as clearly as though they were part of a recent experience. Dreams, like people, may make their appearance once and never come back; or the same person may dream the same thing repeatedly, either in the same form or with slight alterations. In short, these scraps of mental activity at night-time have at command an immense repertory, can in fact create everything that by day the mind is capable of—only, it is never the same.

One might attempt to account for these diversities in dream by assuming that they correspond to different intermediate states between sleeping and waking, different levels of imperfect sleep. Very well; but then in proportion as the mind approached the waking state there should be not merely an increase in the value, content, and distinctness of the dream-performance, but also a growing perception that it *is* a dream; and it ought not to happen that side by side with a clear and sensible element in the dream there is one which is nonsensical or indistinct, followed again by a good piece of work. It is certain that the mind could not vary its depth of sleep so rapidly as that. This explanation therefore does not help; there is in fact no short cut to an answer.

For the present we will leave the *meaning* of the dream out of question, and try instead, by starting from the common element in dreams, to clear a path to a better understanding of their nature. From the relationship of dreams to sleep we have drawn the conclusion that dreams are the reaction to a stimulus disturbing sleep. As we have heard, this is also the single point at which exact experimental psychology can come to our aid; it affords proof of the fact that stimuli brought to bear during sleep make their appearance in dreams. Many investigations have been made on these lines, culminating in those of Mourly Vold whom I mentioned earlier; we have all, too, been in a position to confirm their results by occasional observations of our own. I will choose some of the earlier experiments to tell you. Maury had tests of this kind carried out on himself. Whilst dreaming, he was made to smell some eau de Cologne, whereupon he dreamt he was in Cairo, in the shop of Johann Maria Farina, and this was followed by some

crazy adventures. Again, someone gave his neck a gentle pinch, and he dreamt of the application of a blister and of a doctor who had treated him when he was a child. Again, they let a drop of water fall on his forehead and he was immediately in Italy, perspiring freely and drinking the white wine of Orvieto.

The striking feature about these dreams produced under experimental conditions will perhaps become still clearer to us in another series of *stimulus* dreams. These are three dreams of which we have an account by a clever observer, Hildebrandt, and all three are reactions to the sound of an alarm-clock:

"I am going for a walk on a spring morning, and I saunter through fields just beginning to grow green, till I come to a neighbouring village, where I see the inhabitants in holiday attire making their way in large numbers to the church, their hymn-books in their hands. Of course! it is Sunday and the morning service is just about to begin. I decide to take part in it, but first as I am rather overheated I think I will cool down in the churchyard which surrounds the church. Whilst reading some of the epitaphs there I hear the bell-ringer go up into the tower, where I now notice, high up, the little village bell which will give the signal for the beginning of the service. For some time yet it remains motionless, then it begins to swing, and suddenly the strokes ring out, clear and piercing—so clear and piercing that they put an end to my sleep. But the sound of the bell comes from the alarm-clock."

Here is another combination of images. "It is a bright winter day, and the roads are deep in snow. I have promised to take part in a sleighing expedition, but I have to wait a long time before I am told that the sleigh is at the door. Now follow the preparations for getting in, the fur rug is spread out and the foot-muff fetched and finally I am in my place. But there is still a delay while the horses wait for the signal to start. Then the reins are jerked and the little bells, shaken violently, begin their familiar janizary music, so loudly that in a moment the web of the dream is rent. Again it is nothing but the shrill of the alarm-clock."

Now for the third example! "I see a kitchen-maid with dozens of piled-up plates going along the passage to the dining-room. It seems to me that the pyramid of china in her arms is in danger of overbalancing. I call out a warning: 'Take care, your whole load will fall to the ground.' Of course I receive the usual answer: that they are accustomed to carrying

china in that way, and so on; meanwhile I follow her as she goes with anxious looks. I thought so—the next thing is a stumble on the threshold, the crockery falls, crashing and clattering in a hundred pieces on the ground. But—I soon become aware that that interminably prolonged sound is no real crash, but a regular ringing—and this ringing is due merely to the alarm-clock, as I realize at last on awakening.”

These dreams are very pretty, perfectly sensible, and by no means so incoherent as dreams usually are. We have no quarrel with them on those grounds. The thing common to them all is that in each case the situation arises from a noise, which the dreamer on waking recognizes as that of the alarm-clock. Hence we see here how a dream is produced, but we find out something more. In the dream there is no recognition of the clock, which does not even appear in it, but for the noise of the clock another noise is substituted; the stimulus which disturbs sleep is interpreted, but interpreted differently in each instance. Now why is this? There is no answer; it appears to be mere caprice. But to understand the dream we should be able to account for its choice of just this noise and no other to interpret the stimulus given by the alarm-clock. In analogous fashion we must object to Maury's experiments that, although it is clear that the stimulus brought to bear on the sleeper does appear in the dream, yet his experiments don't explain why it appears exactly in that form, which is one that does not seem explicable by the nature of the stimulus disturbing sleep. And further, in Maury's experiments there was mostly a mass of other dream-material attached to the direct result of the stimulus, for example, the crazy adventures in the eau de Cologne dream, for which we are at a loss to account.

Now will you reflect that the class of dreams which wake one up affords the best opportunity for establishing the influence of external disturbing stimuli. In most other cases it will be more difficult. We do not wake up out of all dreams, and if in the morning we remember a dream of the night before, how are we to assign it to a disturbing stimulus operating perhaps during the night? I once succeeded in subsequently establishing the occurrence of a sound-stimulus of this sort, but only, of course, because of peculiar circumstances. I woke up one morning at a place in the Tyrolese mountains knowing that I had dreamt that the Pope was dead. I could not explain the dream to

myself, but later my wife asked me: “Did you hear quite early this morning the dreadful noise of bells breaking out in all the churches and chapels?” No, I had heard nothing, my sleep is too sound, but thanks to her telling me this I understood my dream. How often may such causes of stimulus as this induce dreams in the sleeper without his ever hearing of them afterwards? Possibly very often: and possibly not. If we can get no information of any stimulus we cannot be convinced on the point. And apart from this we have given up trying to arrive at an estimation of the sleep-disturbing external stimuli, since we know that they only explain a fragment of the dream and not the whole dream-reaction.

We need not on that account give up this theory altogether; there is still another possible way of following it out. Obviously it is a matter of indifference what disturbs sleep and causes the mind to dream. If it cannot always be something external acting as a stimulus to one of the senses, it is possible that, instead, a stimulus operates from the internal organs—a so-called somatic stimulus. This supposition lies very close, and moreover it corresponds to the view popularly held with regard to the origin of dreams, for it is a common saying that they come from the stomach. Unfortunately, here again we must suppose that in very many cases information respecting a somatic stimulus operating during the night would no longer be forthcoming after waking, so that it would be incapable of proof. But we will not overlook the fact that many trustworthy experiences support the idea that dreams may be derived from somatic stimuli; on the whole it is indubitable that the condition of the internal organs can influence dreams. The relation of the content of many dreams to distention of the bladder or to a condition of excitation of the sex-organs is so plain that it cannot be mistaken. From these obvious cases we pass to others, in which, to judge by the content of the dream, we are at least justified in suspecting that some such somatic stimuli have been at work, since there is something in this content which can be regarded as elaboration, representation, or interpretation of these stimuli. Scherner, the investigator of dreams (1861), emphatically supported the view which traces the origin of dreams to organic stimuli, and contributed some excellent examples towards it. For instance, he sees in a dream “two rows of beautiful boys, with fair hair and delicate complexions, confronting each other

pugnaciously, joining in combat, seizing hold of one another, and again letting go their hold, only to take up the former position and go through the whole process again"; his interpretation of the two rows of boys as the teeth is in itself plausible and seems to receive full confirmation when after this scene the dreamer "pulls a long tooth from his jaw." Again, the interpretation of "long, narrow, winding passages" as being suggested by a stimulus originating in the intestine seems sound and corroborates Scherner's assertion that dreams primarily endeavour to represent, by like objects, the organ from which the stimulus proceeds.

We must therefore be prepared to admit that internal stimuli can play the same rôle in dreams as external ones. Unfortunately, evaluation of this factor is open to the same objections. In a great number of instances the attribution of dreams to somatic stimuli must remain uncertain or incapable of proof; not all dreams, but only a certain number of them, rouse the suspicion that stimuli from internal organs have something to do with their origin; and lastly, the internal somatic stimulus will suffice no more than the external sensory stimulus to explain any other part of the dream than the direct reaction to it. The origin of all the rest of the dream remains obscure.

Now, however, let us direct our attention to a certain peculiarity of the dream-life which appears when we study the operation of these stimuli. The dream does not merely reproduce the stimulus, but elaborates it, plays upon it, fits it into a context, or replaces it by something else. This is a side of the dream-work which is bound to be of interest to us because possibly it may lead us nearer to the true nature of dreams. The scope of a man's production is not necessarily limited to the circumstance which immediately gives rise to it. For instance, Shakespeare's *Macbeth* was written as an occasional drama on the accession of the king who first united in his person the crowns of the three kingdoms. But does this historical occasion cover the whole content of the drama, or explain its grandeur and its mystery? Perhaps in the same way the external and internal stimuli operating upon the sleeper are merely the occasion of the dream and afford us no insight into its true nature.

The other element common to all dreams, their peculiarity in mental life, is on the one hand very difficult to grasp and on the other seems to afford no clue for further inquiry.

Our experiences in dreams for the most part take the form of visual images. Can these be explained by the stimuli? Is it really the stimulus that we experience? If so, why is the experience visual, when it can only be in the very rarest instance that any stimulus has operated upon our eyesight? Or, can it be shown that when we dream of speech any conversation or sounds resembling conversation reached our ears during sleep? I venture to discard such a possibility without any hesitation whatever.

If we cannot get any further with the common characteristics of dreams as a starting-point, let us try beginning with their differences. Dreams are often meaningless, confused, and absurd, yet there are some which are sensible, sober, and reasonable. Let us see whether these latter sensible dreams can help to elucidate those which are meaningless. I will tell you the latest reasonable dream which was told to me, the dream of a young man: "I went for a walk in the Kärntnerstrasse and there I met Mr. X; after accompanying him for a short time I went into a restaurant. Two ladies and a gentleman came and sat down at my table. At first I was annoyed and refused to look at them, but presently I glanced across at them and found that they were quite nice." The dreamer's comment on this was that the evening before he had actually been walking in the Kärntnerstrasse, which is the way he usually goes, and that he had met Mr. X there. The other part of the dream was not a direct reminiscence, but only bore a certain resemblance to an occurrence of some time previously. Or here we have another prosaic dream, that of a lady. Her husband says to her: "Don't you think we ought to have the piano tuned?" and she replies: "It is not worth it, for the hammers need fresh leather anyhow." This dream repeats a conversation which took place in almost the same words between herself and her husband the day before the dream. What then do we learn from these two prosaic dreams? Merely that there occur in them recollections of daily life or of matters connected with it. Even that would be something if it could be asserted of all dreams without exception. But that is out of the question; this characteristic too belongs only to a minority of dreams. In most dreams we find no connection with the day before, and no light is thrown from this quarter upon meaningless and absurd dreams. All we know is that we have met with a new problem. Not only do we want to know what a dream is saying, but, if, as in our examples,

that is quite plain, we want to know further from what cause and to what end we repeat in dreams this which is known to us and has recently happened to us.

I think you would be as tired as I of continuing the kind of attempts we have made up to this point. It only shows that all the interest in the world will not help us with a problem unless we have also an idea of some path to adopt in order to arrive at a solution. Till now we have not found this path. Experimental psychology has contributed nothing but some (certainly very valuable) information about the significance of stimuli in the production of dreams. Of philosophy we have nothing to expect, unless it be a lofty repetition of the reproach that our object is intellectually contemptible; while from the occult sciences we surely do not choose to borrow. History and the verdict of the people tell us that dreams are full of meaning and importance, and of prophetic significance; but that is hard to accept and certainly does not lend itself to proof. So then our first endeavours are completely baffled.

But unexpectedly there comes a hint from a direction in which we have not hitherto looked. Colloquial speech, which is certainly no matter of chance but the deposit, as it were, of ancient knowledge—a thing which must not indeed be made too much of—our speech, I say, recognizes the existence of something to which, strangely enough, it gives the name of *day-dreams*. Day-dreams are phantasies (products of phantasy); they are very common phenomena, are observable in healthy as well as in sick persons, and they also can easily be studied by the subject himself. The most striking thing about these “phantastic” creations is that they have received the name of *day-dreams*, for they have nothing in common with the two universal characteristics of dreams. Their name contradicts any relationship to the condition of sleep and, as regards the second universal characteristic, no experience or hallucination takes place in them, we simply imagine something; we recognize that they are the work of phantasy, that we are not seeing but thinking. These day-dreams appear before puberty, often indeed in late childhood, and persist until maturity is reached when they are either given up or retained as long as life lasts. The content of these phantasies is dictated by a very transparent motivation. They are scenes and events which gratify either the egoistic cravings of ambition or thirst for power, or the erotic desires of

the subject. In young men, ambitious phantasies predominate; in women, whose ambition centres on success in love, erotic phantasies; but the erotic requirement can often enough in men too be detected in the background, all their heroic deeds and successes are really only intended to win the admiration and favour of women. In other respects these day-dreams show great diversity and their fate varies. All of them are either given up after a short time and replaced by a new one, or retained, spun out into long stories, and adapted to changing circumstances in life. They march with the times; and they receive as it were “date-stamps” upon them which show the influence of new situations. They form the raw material of poetic production; for the writer by transforming, disguising, or curtailing them creates out of his day-dreams the situations which he embodies in his stories, novels, and dramas. The hero of a day-dream is, however, always the subject himself, either directly imagined in the part or transparently identified with someone else.

Perhaps day-dreams are so called on account of their similar relation to reality, as an indication that their content is no more to be accepted as real than is that of dreams. But it is possible that they share the name of dreams because of some mental characteristic of the dream which we do not yet know but after which we are seeking. On the other hand, it is possible that we are altogether wrong in regarding this similarity of name as significant. That is a question which can only be answered later.

## SIXTH LECTURE

### PRELIMINARY HYPOTHESES AND TECHNIQUE OF INTERPRETATION

WE THUS realize our need of a new way of approach, a definite method, if we are to make any advance in our researches into dreams. I will now offer an obvious suggestion: let us accept as the basis of the whole of our further enquiry the following hypothesis—that dreams are not a somatic, but a mental, phenomenon. You know what this means; but what is our justification in making this assumption? We have none, but on the other hand there is nothing to prevent us. The position is this: if the dream is a somatic phenomenon, it does not concern us; it can only be of interest to us on the hypothesis that it is a mental phenomenon. So we will assume that this hypothesis is true, in order to see what happens if we do so. The

results of our work will determine whether we may adhere to the assumption, and uphold it in its turn as an inference fairly drawn. Now what exactly is the object of this enquiry of ours, or to what are we directing our efforts? Our object is that of all scientific endeavour—namely, to achieve an understanding of the phenomena, to establish a connection between them, and, in the last resort, wherever it is possible to increase our power over them.

So we continue our work on the assumption that dreams are a mental phenomenon. In that event, they are a performance and an utterance on the part of the dreamer, but of a kind that conveys nothing to us, and which we do not understand. Now supposing that I give utterance to something that you do not understand, what do you do? You ask me to explain, do you not? Why may not we do the same—ask the dreamer the meaning of the dream?

Remember, we have already found ourselves in a similar position. It was when we were enquiring into certain errors, and the instance we took was a slip of the tongue. Someone had said: "Then certain things were *re-filled*," and thereupon we asked—no, fortunately it was not *we* who asked, but other people who had nothing to do with psycho-analysis—they asked what he meant by this enigmatic expression. He answered at once that what he had intended to say was: "That was a filthy business," but had checked himself and substituted the milder words: "Things were revealed there." I explained to you then that this enquiry was the model for every psycho-analytic investigation, and you understand now that psycho-analytic technique endeavours as far as possible to let the persons being analysed give the answer to their own problems. The dreamer himself then should interpret his dream for us.

That is not so simple with dreams, however, as we all know. Where errors were concerned, this method proved possible in many cases; there were others where the person questioned refused to say anything and even indignantly repudiated the answer suggested to him. With dreams, instances of the first type are entirely lacking; the dreamer always says he knows nothing about it. He cannot very well repudiate our interpretation, since we have none to offer him. Shall we have to give up our attempt then? Since *he* knows nothing, and *we* know nothing, and a third person can surely know nothing either, there cannot be any prospect of finding the answer. Well, if you like, give up the attempt. But if you are not so minded, you can

accompany me. For I assure you that it is not only quite possible, but highly probable, that the dreamer really does know the meaning of his dream; *only he does not know that he knows, and therefore thinks that he does not.*

At this point you will probably call my attention to the fact that I am again introducing an assumption, the second in quite a short context, and that by so doing I greatly detract from the force of my claim to a trustworthy method of procedure. Given the hypothesis that dreams are a mental phenomenon, and given further the hypothesis that there are in the minds of men certain things which they know without knowing that they know them—and so forth! You have only to keep in view the intrinsic improbability of both these hypotheses, and you may with an easy mind abandon all interest in the conclusions to be drawn from them.

Well, I have not brought you here either to delude you or to conceal anything from you. True, I announced that I would give a course of lectures entitled "Introductory Lectures on Psycho-analysis"; but it was no part of my purpose to play the oracle, professing to show you an easy sequence of facts, whilst carefully concealing all difficulties, filling up gaps, and glossing over doubtful points, so that you might comfortably enjoy the belief that you have learnt something new. No, it is the very fact that you are beginners that makes me anxious to show you our science as it is, with all its excrescences and crudities, the claims that it makes and the criticism to which it may give rise. I know, indeed, that it is the same in every science and that, especially in the beginnings, it cannot be otherwise. I know too that, in teaching other sciences, an effort is made at first to hide these difficulties and imperfections from the learner. But that cannot be done in psycho-analysis. So I really have set up two hypotheses, the one within the other; and anyone who finds it all too laborious, or too uncertain, or who is used to higher degrees of certainty, or to more refined deductions, need go no further with me. Only I should advise him to leave psychological problems altogether alone, for it is to be feared that this is a field in which he will find no access to such exact and sure paths as he is prepared to tread. And further, it is quite superfluous for any science which can offer a real contribution to knowledge to strive to make itself heard and to win adherents. Its reception must depend upon its

results, and it can afford to wait until these have compelled attention.

But I may warn those of you who are not to be deterred in this way that my two assumptions are not of equal importance. The first, that dreams are a mental phenomenon, is the hypothesis which we hope to prove by the results of our work. The second has already been proved in a different field, and I am merely taking the liberty of transferring it thence to our problems.

Where, and in what connection, is it supposed to have been proved that a man can possess knowledge without knowing that he does so, which is the assumption we are making of the dreamer? Surely that would be a remarkable and surprising fact, which would change our conception of mental life and would have no need of concealment. Incidentally, it would be a fact belied in the very statement of it, which yet intends to be literally true—a contradiction in terms. There is not, however, any attempt at concealment. We cannot blame the fact for people's ignorance of it, or lack of interest in it, any more than we ourselves are to blame because all these psychological problems have been passed in judgment by persons who have held aloof from all the observations and experiments which alone can be conclusive.

The proof to which I refer was found in the sphere of hypnotic phenomena. In the year 1889 I was present at the remarkably impressive demonstrations by Liébault and Bernheim, in Nancy, and there I witnessed the following experiment. A man was placed in a condition of somnambulism, and then made to go through all sorts of hallucinatory experiences. On being awakened, he seemed at first to know nothing at all of what had taken place during his hypnotic sleep. Bernheim then asked him in so many words to tell him what had happened while he was under hypnosis. The man declared that he could not remember anything. Bernheim, however, insisted upon it, pressed him, and assured him that he did know and that he must remember, and lo and behold! the man wavered, began to reflect, and remembered in a shadowy fashion first one of the occurrences which has been suggested to him; then something else, his recollection growing increasingly clear and complete until finally it was brought to light without a single gap. Now, since in the end he had the knowledge without having learnt anything from any other quarter in the meantime, we are justified in concluding that these recollections were in his mind from the outset.

They were merely inaccessible to him; he did not know that he knew them but believed that he did not know. In fact, his case was exactly similar to what we assume the dreamer's to be.

I hope you are duly surprised that this fact is already established and that you will ask me: "Why did you not refer to this proof before, when we were considering errors and came to the point of ascribing to a man who had made a slip of the tongue intentions behind his speech, of which he knew nothing, and which he denied? If it is possible for a man to believe that he knows nothing of experiences of which nevertheless he does possess the recollection, it seems no longer improbable that there should be other mental processes going on within him about which also he knows nothing. We should certainly have been impressed by this argument and should have been in a better position to understand about errors." Certainly, I might have brought forward this proof then, but I reserved it for a later occasion when there would be more need for it. Some of the errors explained themselves, others suggested to us that, in order to understand the connection between the phenomena, it would be advisable to postulate the existence of mental processes of which the person is entirely ignorant. With dreams we are compelled to seek our explanations elsewhere, and besides, I am counting on your being more ready to accept in this connection a proof from the field of hypnosis. The condition in which we perform errors must seem to you normal and, as such, to bear no similarity to that of hypnosis. On the other hand, there exists a clear relationship between the hypnotic state and sleep, the essential condition of dreaming. Hypnosis is actually called *artificial sleep*; we say to the people whom we hypnotize: "Sleep," and the suggestions made to them are comparable to the dreams of natural sleep. The mental situation is really analogous in the two cases. In natural sleep we withdraw our interest from the whole outer world; so also in hypnotic sleep, with the exception of the one person who has hypnotized us and with whom we remain in rapport. Again, the so-called "nurse's sleep" in which the nurse remains in rapport with the child and can be awakened only by him is a normal counterpart of hypnotic sleep. So it does not seem so very audacious to carry over to natural sleep something which is a condition in hypnosis. The assumption that some knowledge about his dream exists in the dreamer and that this knowledge is merely inaccessible

sible to him, so that he himself does not believe he has it, is not a wild invention. Incidentally, we observe here that a third way of approaching the study of dreams is thus opened out for us; we may approach it by the avenue of sleep-disturbing stimuli, by that of day-dreams, and now by that of the dreams suggested during hypnosis.

Now perhaps we shall return to our task with greater confidence. We see it is very probable that the dreamer knows something about his dream; the problem is how to make it possible for him to get at his knowledge and impart it to us. We do not expect him immediately to tell us what his dream means, but we do think he will be able to discover its source, from what circle of thoughts and interests it is derived. With errors, you will remember the man was asked how the slip of the tongue "re-filled" had come about, and his first association gave us the explanation. The technique we employ in the case of dreams is very simple and is modelled on this example. Here again we shall ask the dreamer how he came to have the dream, and his next words must be regarded as giving the explanation in this case also. It makes no difference to us, therefore, whether he thinks that he does or does not know anything about it, and we treat both cases alike.

This technique is certainly very simple, nevertheless I am afraid it will provoke most strenuous opposition in you. You will say: "Another assumption, the third! And the most improbable of all! When I ask the dreamer what ideas come to him about the dream, do you mean to say that his very first association will give the desired explanation? But surely he might have no association at all, or heaven only knows what the association might be. We cannot imagine upon what grounds such an expectation is based. It really implies too much trust in Providence, and this at a point where rather more exercise of the critical faculty would better meet the case. Besides, a dream is not like a single slip of the tongue but is made up of many elements. That being so, upon which association is one to rely?"

You are right in all the unessentials. It is true that a dream differs from a slip of the tongue in the matter of its many elements as well as in other points. We must take account of that in our technique. So I suggest to you that we divide the dream up into its various elements, and examine each element separately; then we shall have re-established the analogy with a slip of the tongue. Again, you are right

in saying that the dreamer, when questioned on the single elements of the dream, may reply that he has no ideas about them. There are cases in which we accept this answer, and later I will tell you which these are; curiously enough, they are cases about which we ourselves may have certain definite ideas. But in general, when the dreamer declares that he has no ideas, we shall contradict him, press him to answer, assure him that he must have some idea and—shall find we are right. He will produce an association, any one, it does not matter to us what it is. He will be especially ready with information which we may term historical. He will say: "That is something which happened yesterday" (as in the instance of the two *prosaic* dreams quoted above) or: "That reminds me of something which happened recently," and in this way we shall come to notice that dreams are much more often connected with impressions of the day before than we thought at first. Finally, with the dream as his starting-point, he will recall events which happened less recently, and at last even some which lie very far back in the past.

In regard to the main issue, however, you are wrong. When you think it arbitrary to assume that the first association of the dreamer must give us just what we are looking for, or at any rate lead to it, and further, that the association is much more likely to be quite capricious and to have no connection with what we are looking for, and that it only shows my blind trust in Providence if I expect anything else—then you make a very great mistake. I have already taken the liberty of pointing out to you that there is within you a deeply rooted belief in psychic freedom and choice, that this belief is quite unscientific, and that it must give ground before the claims of a determinism which governs even mental life. I ask you to have some respect for the *fact* that that one association, and nothing else, occurs to the dreamer when he is questioned. Nor am I setting up one belief against another. It can be proved that the association thus given is not a matter of choice, nor indeterminate, and that it is not unconnected with what we are looking for. Indeed, I have recently learnt—not that I attach too much importance to the fact—that experimental psychology itself has brought forward similar proofs.

Because of the importance of the matter I ask you to pay special attention to this. When I ask a man to say what comes to his mind about any given element in a dream, I require

him to give himself up to the process of FREE ASSOCIATION *which follows when he keeps in mind the original idea*. This necessitates a peculiar attitude of the attention, something quite different from reflection, indeed, precluding it. Many people adopt this attitude without any difficulty, but others when they attempt to do so display an incredible inaptitude. There is a still higher degree of freedom in association which appears when I dispense with any particular stimulus-idea and perhaps only describe the kind and species of association that I want; for example, ask someone to let a proper name or a number occur to him. An association of this sort should, one would say, be even more subject to choice and unaccountable than the kind used in our technique. Nevertheless, it can be shown that in every instance it will be strictly determined by important inner attitudes of mind, which are unknown to us at the moment when they operate, just as much unknown as are the disturbing tendencies which cause errors, and those tendencies which bring about so-called "chance" actions.

I myself and many after me have repeatedly made an examination of names and numbers called up without any particular idea as a starting-point; some of these experiments have been published. The method is this: a train of associations is stirred up by the name which occurred, and these associations, as you see, are no longer quite free, but are attached just so far as the associations to the different elements of the dream are attached; this train of associations is then kept up until the thoughts arising from the impulse have been exhausted. By that time, however, you will have explained the motivation and significance of the free association with a name. The experiments yield the same result again and again; the information they give us often includes a wealth of material and necessitates going far afield into its ramifications. The associations to numbers that arise spontaneously are perhaps the most demonstrative; they follow upon one another so swiftly and make for a hidden goal with such astounding certainty that one is really quite taken aback. I will give you just one example of a name-analysis of this sort, because it happens to be one which does not involve the handling of a great mass of material.

Once, when I was treating a young man, I happened to say something on this subject and to assert that, in spite of our apparent freedom of choice in such matters, we cannot, in point of fact, think of any name which cannot be

shown to be narrowly determined by the immediate circumstances, the idiosyncrasies, of the person experimented with and his situation at the moment. As he was inclined to be sceptical, I proposed that he should make the experiment himself then and there. I knew that he had usually numerous relationships of all sorts with women and girls, so I told him that I thought he would have an exceptionally large number to choose from if he were to let the name of a woman occur to him. He agreed. To my surprise, or rather perhaps to his own, he did not overwhelm me with an avalanche of women's names, but remained silent for a time, and then confessed that the only name which came into his mind at all was "Albine." "How curious! What do you connect with this name? How many Albines do you know?" Strangely enough, he knew no one of the name of Albine, and he found no associations to the name. One might infer that the analysis had failed; but no, it was already complete, and no further association was required. The man himself was unusually fair in colouring, and whilst talking to him in analysis I had often jokingly called him an *albino*; moreover, we were just in the midst of tracing the *feminine* element in his nature. So it was he himself who was this female albino, the *woman* who interested him most at the moment.

In the same way, the tunes which suddenly come into a man's head can be shown to be conditioned by some train of thought to which they belong, and which for some reason is occupying his mind without his knowing anything about it. It is easy to show that the connection with the tune is to be sought either in the words which belong to it or in the source from which it comes: I must, however, make this reservation, that I do not maintain this in the case of really musical people of whom I happen to have had no experience; in them the musical value of the tune may account for its suddenly emerging into consciousness. The first case is certainly much more common; I know of a young man who for some time was absolutely haunted by the tune (a charming one, I admit) of the song of Paris in *Helen of Troy*, until his attention was drawn in analysis to the fact that at that time an "Ida" and a "Helen" were rivals in his interest.

If, then, the associations which arise quite freely are determined in this way and belong to some definite context, we are surely justified in concluding that associations attached to one single stimulus-idea must be equally narrow-

ly conditioned. Examination shows as a fact that they are not only attached in the first place to the stimulus-idea which we have provided for them, but that they are also dependent, in the second place, on circles of thoughts and interests of strong affective value (*complexes*, as we call them) of whose influence at the time nothing is known, that is to say, on unconscious activities.

Associations attached in this way have been made the subject of very instructive experiments, which have played a notable part in the history of psycho-analysis. Wundt's school originated the so-called *association-experiment*, in which the subject of the experiment is bidden to reply to a given *stimulus-word* as quickly as possible with whatever *reaction-word* occurs to him. The following points may then be noted: the interval which elapses between the utterance of the stimulus-word and of the reaction-word, the nature of the latter, and possibly any mistake which comes in when the same experiment is repeated later, and so on. The Zurich School, under the leadership of Bleuler and Jung, arrived at the explanation of the reactions to the association-experiment by asking the person experimented upon to throw light upon any associations which seemed at all remarkable, by means of subsequent associations. In this way it became clear that these unusual reactions were most strictly determined by the complexes of the person concerned. By this discovery Bleuler and Jung built the first bridge between experimental psychology and psycho-analysis.

Having heard this you may possibly say: "We admit now that free associations are subject to determination and not a matter of choice, as we thought at first, and we admit this also in the case of associations to the elements of dreams. But it is not this that we are bothering about. You maintain that the association to each element in the dream is determined by some mental background to this particular element, a background of which we know nothing. We cannot see that there is any proof of this: Naturally we expect that the association to the dream-element will be shown to be conditioned by one of the complexes of the dreamer, but what good is that to us? That does not help us to understand the dream; it merely leads to some knowledge of these so-called 'complexes,' as did the association-experiment; but what have these to do with the dream?"

You are right, but you are overlooking an

important point, the very thing which deterred me from choosing the association-experiment as a starting-point for this discussion. In this experiment, the stimulus-word, the single thing which determines the reaction, is chosen by us at will, and the reaction stands as intermediary between this stimulus-word and the complex aroused in the person experimented upon. In the dream, the stimulus-word is replaced by something derived from the mental life of the dreamer, from sources unknown to him, and hence may very probably be itself a *derivative of a complex*. It is not, therefore, altogether fantastic to suppose that the further associations connected with elements of the dream are determined by no other complex than that which has produced the particular element itself, and that they will lead to the discovery of that complex.

Let me give you another instance which may serve to show that, in the case of dreams, the facts bear out our expectations. The forgetting of proper names is really an excellent prototype of what happens in dream-analysis, only that in the former case one person alone is concerned, while in the interpretation of dreams there are two. When I forget a name temporarily, I am still certain that I know it, and by way of a *détour* through Bernheim's experiment, we are now in a position to achieve a similar certainty in the case of the dreamer. Now this name which I have forgotten, and yet really know, eludes me. Experience soon teaches me that no amount of thinking about it, even with effort, is any use. I can, however, always think of another or of several other names instead of the forgotten one. When such a substitute name occurs to me spontaneously, only then is the similarity between this situation and that of dream-analysis evident. The dream-element also is not what I am really looking for; it is only a substitute for something else, for the real thing which I do not know and am trying to discover by means of dream-analysis. Again the difference is that when I forget a name I know perfectly well that the substitute is not the right one, whereas we only arrived at this conception of the dream-element by a laborious process of investigation. Now there also is a way in which, when we forget a name, we can by starting from the substitute, arrive at the real thing eluding our consciousness at the moment, i.e., the forgotten name. If I turn my attention to these substitute names and let further associations to them come into my mind, I arrive after a short or

a long way around at the name I have forgotten, and in so doing I discover that the substitutes I have spontaneously produced had a definite connection with, and were determined by, the forgotten name.

I will give you an instance of an analysis of this sort: One day I found that I could not call to mind the name of the small country on the Riviera, of which Monte Carlo is the capital. It was most annoying, but so it was. I delved into all my knowledge about the country; I thought of Prince Albert of the House of Lusignan, of his marriages, of his passion for deep-sea exploration—in fact of everything I could summon up, but all to no purpose. So I gave up trying to think and, instead of the name I had lost, let substitute names come into my mind. They came quickly: Monte Carlo itself, then Piedmont, Albania, Montevideo, Colico. Albania was the first to attract my attention; it was immediately replaced by Montenegro, probably because of the contrast between black and white. Then I noticed that four of the substitute names have the same syllable “mon,” and immediately I recalled the forgotten word and cried out “Monaco.” You see the substitutes really originated in the forgotten name; the four first came from the first syllable and the last gave the sequence of the syllables and the whole of the final syllable. Incidentally, I could quite easily find out what had made me forget the name for the time being. Monaco is the Italian name for Munich, and it was some thoughts connected with this town which had acted as an inhibition.

Now that is a very pretty example, but it is too simple. In other cases you might have to take a longer succession of associations to the substitute name, and then the analogy to dream-analysis would be clearer. I have had experiences of that sort, too. A stranger once invited me to drink some Italian wine with him, and in the inn he found he had forgotten the name of the wine which he had meant to order on account of his very pleasant recollections of it. A number of dissimilar substitute names occurred to him, and from these I was able to infer that the thought of someone called Hedwig had made him forget the name of the wine. Sure enough, not only did he tell me that there had been a Hedwig with him on the occasion when he first tasted the wine, but this discovery brought back to him the name he wanted. He was now happily married, and Hedwig belonged to earlier days which he did not care to recall.

What is possible in the case of forgotten names must be also possible in the interpretation of dreams: starting from the substitute, we must be able to arrive at the real object of our search by means of a train of associations; and further, arguing from what happens with forgotten names, we may assume that the associations to the dream-element will have been determined not only by that element but also by the real thought which is not in consciousness. If we could do this, we should have gone some way towards justifying our technique.

## SEVENTH LECTURE

### MANIFEST CONTENT AND LATENT THOUGHTS

YOU see that our study of errors has not been fruitless. Thanks to our exertions in that direction, we have—reasoning from the hypotheses with which you are familiar—secured two results: a conception of the nature of the dream-element and a technique of dream-interpretation. The conception of the dream-element is as follows: it is not in itself a primary and essential thing, a *thought proper*, but a substitute for something else unknown to the person concerned, just as is the underlying intention of the error, a substitute for something the knowledge of which is indeed possessed by the dreamer but is inaccessible to him. We hope to be able to carry over the same conception on to the dream as a whole, which consists of a number of such elements. Our method is to allow other substitute-ideas, from which we are able to divine that which lies hidden, to emerge into consciousness by means of free association to the said elements.

I am now going to propose that we introduce an alteration in our nomenclature in order to make our terminology more flexible. Instead of using the words *hidden*, *inaccessible* or *proper*, let us give a more precise description and say *inaccessible to the consciousness of the dreamer* or *unconscious*. By that we mean nothing more than was implied in the case of the forgotten word, or the underlying intention responsible for the error; that is to say, *unconscious at the moment*. It follows that in contradistinction we may call the dream-elements themselves, and those substitute-ideas arrived at by the process of association, *conscious*. No theoretical implication is so far contained in these terms; no exception can be taken to the use of the word *unconscious* as a description at once applicable and easy to understand.

Now, transferring our conception from the single element to the dream as a whole, it follows that the latter is the distorted substitute for something else, something unconscious, and that the task of dream interpretation is to discover these unconscious thoughts. Hence are derived three important rules which should be observed in the work of dream-interpretation:

1. We are not to trouble about the surface meaning of the dream, whether it be reasonable or absurd, clear or confused; in no case does it constitute the unconscious thoughts we are seeking. (An obvious limitation of this rule will force itself upon us later.)

2. We are to confine our work to calling up substitute-ideas for every element and not to ponder over them and try to see whether they contain something which fits in, nor to trouble ourselves about how far they are taking us from the dream-element.

3. We must wait until the hidden unconscious thoughts which we are seeking appear of their own accord, just as in the case of the missing word "Monaco" in the experiment which I described.

Now we understand also how entirely indifferent it is whether we remember much or little of our dreams, above all whether we remember them accurately or not. The dream as remembered is not the real thing at all, but a *distorted substitute* which, by calling up other substitute-ideas, provides us with a means of approaching the thought proper, of bringing into consciousness the unconscious thoughts underlying the dream. If our recollection was at fault, all that has happened is that a further distortion of the substitute has taken place, and this distortion itself cannot be without motivation.

We can interpret our own dreams as well as those of others; indeed, we learn more from our own and the process carries more conviction. Now if we experiment in this direction, we notice that something is working against us. Associations come, it is true, but we do not admit them all; we are moved to criticize and to select. We say to ourselves of one association: "No, that does not fit in—it is irrelevant," and of another: "That is too absurd," and of a third: "That is quite beside the point"; and then we can observe further that in making such objections we stifle, and in the end actually banish, the associations before they have become quite clear. So on the one hand we tend to hold too closely to the initial idea, that is, the dream-element itself, and on the other,

by allowing ourselves to select, we vitiate the results of the process of free association. If we are not attempting the interpretation by ourselves, but are allowing someone else to interpret, we shall clearly perceive another motive impelling us to this selection, forbidden as we know it to be. We find ourselves thinking at times: "No, this association is too unpleasant; I cannot, or will not, tell it to him."

Clearly these objections threaten to spoil the success of our work. We must guard against them when we are interpreting our own dreams by resolving firmly not to yield to them, and, in interpreting those of someone else, by laying down the hard and fast rule that he must not withhold any association, even if one of the four objections I have named rises up against it, namely, that it is too unimportant, too absurd, too irrelevant or too unpleasant to speak of. He promises to keep this rule, and we may well feel annoyed when we find how badly he fulfils his promise later on. At first we account for this by imagining that, in spite of our authoritative assurance, he is not convinced that the process of free association will be justified by its results; and perhaps our next idea will be to win him over first to our theory, by giving him books to read or sending him to lectures so that he may be converted to our views on the subject. But we shall be saved from any such false steps by observing that the same critical objections against certain associations arise even in ourselves, whom we surely cannot suspect of doubt, and can only subsequently, on second thoughts as it were, be overcome.

Instead of being annoyed at the dreamer's disobedience, we can turn this experience to good account as a means of learning something new, something which is the more important the more unprepared we were for it. We realize that the work of dream-interpretation is encountering opposition by a *resistance* which expresses itself in this very form of critical objections. This resistance is independent of the theoretical conviction of the dreamer. We learn even more than this. Experience shows that a critical objection of this nature is never justified. On the contrary, the associations which people wish to suppress in this way prove *without exception* to be the most important, to be decisive for the discovery of the unconscious thought. When an association is accompanied by an objection of this sort it positively calls for special notice.

This resistance is something entirely new; a phenomenon which we have found by following out our hypotheses, although it was not included in them. We are not altogether agreeably surprised by this new factor which we have to reckon with, for we suspect already that it will not make our work any easier: it might almost tempt us to give up the effort with dreams altogether. To take such a trivial subject and then to have so much trouble, instead of spinning along smoothly with our technique! But we might, on the other hand, find these difficulties fascinating and be led to suspect that the work will be worth the trouble. Resistances invariably confront us when we try to penetrate to the hidden unconscious thought from the substitute offered by the dream-element. We may suppose, therefore, that something very significant must be concealed behind the substitute; for, if not, why should we meet with such difficulties, the purpose of which is to keep up the concealment? When a child will not open his clenched fist to show what is in it, we may be quite certain that it is something which he ought not to have.

As soon as we introduce into our subject the dynamic conception of resistance, we must bear in mind that this factor is something quantitatively variable. There are greater and lesser resistances, and we are prepared to find these differences showing themselves in the course of our work. Perhaps we can connect with this another experience also met with in the process of dream-interpretation. I mean that sometimes only a few associations—perhaps not more than one—suffice to lead us from the dream-element to the unconscious thought behind it, whilst on other occasions long chains of associations are necessary and many critical objections have to be overcome. We shall probably think that the number of associations necessary varies with the varying strength of the resistances, and very likely we shall be right. If there is only a slight resistance, the substitute is not far removed from the unconscious thought; a strong resistance on the other hand causes great distortions of the latter, and thereby entails a long journey back from the substitute to the unconscious thought itself.

Perhaps this would be a good moment to select a dream and try our technique upon it, to see whether the expectations we have entertained are realized. Very well, but what dream shall we choose? You do not know how difficult it is for me to decide, nor can I make it clear to you yet what the difficulties are. Obviously

there must be dreams in which on the whole there is very little distortion, and one would think it would be best to begin with these. But which are the least distorted dreams? Those which make good sense and are not confused, of which I have already given you two examples? In assuming this, we should make a great mistake, for examination shows that these dreams have undergone an exceptionally high degree of distortion. Supposing, then, that I make no special condition but take any dream at random, you would probably be very much disappointed. We might have to observe and record such a vast number of associations to the single dream-elements that it would be quite impossible to gain any clear view of the work as a whole. If we write the dream down and compare with it all the associations which it produces, we are likely to find that they have multiplied the length of the text of the dream many times. So the most practical method would seem to be that of selecting for analysis several short dreams, each of which can at least convey some idea to us or confirm some supposition. This will be the course we shall decide to take, unless experience gives us a hint where we ought really to look for slightly distorted dreams.

But I can suggest another means of simplifying matters, one which lies right before us. Instead of attempting the interpretation of whole dreams, let us confine ourselves to single dream elements and find out by taking a series of examples how the application of our technique explains them:

(a) A lady related that as a child she very often dreamt that *God had a pointed paper cap on his head*. How are you going to understand that without the help of the dreamer? It sounds quite nonsensical; but the absurdity disappears when the lady says that as a little girl she used to have a cap like that put on her head at table, because she wouldn't give up looking at the plates of her brothers and sisters to see whether any of them had been given more than she. Evidently the cap was meant to serve the purpose of blinkers; this piece of historical information was given, by the way, without any difficulty. The interpretation of this element and, with it, of the whole short dream becomes easy enough with the help of a further association of the dreamer's: "As I had been told that God knew everything and saw everything, the dream could only mean that I knew and saw everything as God did, even when they tried to prevent me." This example is perhaps too simple.

(b) A sceptical patient had a longer dream, in which certain people were telling her about my book on *Wit* and praising it very highly. Then something else came in about a *canal*; *it might have been another book in which the word canal occurred, or something else to do with a canal . . . she did not know . . . it was quite vague.*

Now you will certainly be inclined to suppose that the *canal* in the dream will defy interpretation on account of its vagueness. You are right in expecting difficulty, but the difficulty is not caused by the vagueness; on the contrary, the difficulty in interpretation is caused by something else, by the same thing that makes the element vague. The dreamer had no association to the word *canal*; naturally I did not know what to say either. Shortly afterwards, to be accurate, on the next day, she told me that an association had occurred to her which *perhaps* had something to do with it. It was in fact a witty remark which some one had told her. On board ship between Dover and Calais a well-known author was talking to an Englishman who in some particular context quoted the words: "*Du sublime au ridicule il n'y a qu'un pas.*" The author answered: "*Oui, le Pas-de-Calais,*" meaning that he regarded France as sublime and England as ridiculous. Of course, the Pas-de-Calais is a *canal*—that is to say, the Canal la Manche—the English Channel. Now, you ask, do I think that this association had anything to do with the dream? Certainly I think so: it gives the true meaning of the puzzling dream-element. Or are you inclined to doubt that the joke already existed before the dream and was the unconscious thought behind the element *canal*, and to maintain that it was a subsequent invention? The association reveals the scepticism disguised under the obtrusive admiration, and resistance was no doubt the cause both of the association being so long in occurring to her, and of the corresponding dream-element being so vague. Observe here the relation between the dream-element and the unconscious thought underlying it: it is, as it were, a fragment of the thought, an allusion to it; by being isolated in that way it became quite incomprehensible.

(c) A patient had a fairly long dream, part of which was as follows: *Several members of his family were seated at a table of a particular shape . . . etc.* This table reminded the dreamer that he had seen one of the same sort when he was visiting a certain family. From that his thoughts ran on thus: in this family the rela-

tion between father and son was a peculiar one, and the patient presently added that his own relations with his father were, as a matter of fact, of the same nature. So the table was introduced into the dream to indicate this parallelism.

It happened that this dreamer had long been familiar with the demands of dream-interpretation; otherwise he might have taken exception to the idea of investigating so trivial a detail as the shape of a table. We do literally deny that anything in the dream is a matter of chance or of indifference, and it is precisely by enquiring into such trivial and (apparently) unmotivated details that we expect to arrive at our conclusion. You may perhaps still be surprised that the dream-work should happen to choose the table, in order to express the thought "Our relationship is just like theirs." But even this is explicable when you learn that the family in question was named *Tischler*. (*Tisch* = table.) In making his relations sit at this table the dreamer's meaning was that they too were *Tischler*. And notice another thing: that in relating dream-interpretations of this sort one is forced into indiscretion. There you have one of the difficulties I alluded to in the matter of choosing examples. I could easily have given you another example instead of this one, but probably I should have avoided this indiscretion only to commit another in its place.

This seems to me a good point at which to introduce two new terms which we might have used already. Let us call the dream as related *the manifest dream-content*, and the hidden meaning, which we should come by in following out the associations, *the latent dream-thoughts*. Then we must consider the relation between the manifest content and the latent thoughts, as shown in the above examples. There are many varieties of these relations. In examples (a) and (b) the manifest dream-element is also an integral part of the latent thoughts, but only a fragment of them. A small piece of a great, composite, mental structure in the unconscious dream-thoughts has made its way into the manifest dream also, in the form of a fragment or in other cases as an allusion, like a catch-word or an abbreviation in a telegraphic code. The interpretation has to complete the whole to which this scrap or allusion belongs, which it did most successfully in example (b). One method of the distorting process in which the dream-work consists is, therefore, that of substituting for something else a

fragment or an allusion. In example (c) we notice, moreover, another possible relation between manifest content and latent thought, a relation which is even more plainly and distinctly expressed in the following examples:

(d) *The dreamer was pulling a certain lady of his acquaintance out of a ditch.* He himself found the meaning of this dream-element by means of the first association. It meant: he picked her out, preferred her.<sup>1</sup>

(e) Another man dreamt *that his brother was digging up his garden all over again.* The first association was to deep-trenching for vegetables, the second gave the meaning. The brother was *retrenching*. (Retrenching his expenses).<sup>2</sup>

(f) *The dreamer was climbing a mountain from which he had a remarkably wide view.* This sounds most reasonable; perhaps no interpretation is called for and we have only to find out what recollection is referred to in the dream, and what had aroused it. No, you are mistaken; it comes out that this dream needed interpretation just as much as any other, more confused. For the dreamer remembers nothing about mountain-climbing himself; instead, it occurs to him that an acquaintance is publishing a *Rundschau* (Review), on the subject of our relations with the most distant parts of the earth: hence, the latent thought is one in which the dreamer identifies himself with the *reviewer* (lit. one who takes a survey).

Here you come across a new type of relation between the manifest and the latent element in dreams. The former is not so much a distortion of the latter as a representation—a plastic, concrete piece of imagery, originating in the sound of a word. It is true that this amounts in effect to a distortion, for we have long forgotten from what concrete image the word sprang, and hence fail to recognize it when that image is substituted for it. When you consider that the manifest dream consists of visual images in by far the greatest number of cases, and less frequently of thoughts and words, you will easily realize that this kind of relation between the manifest and the latent has a special significance in the structure of dreams. You see too that in this way it becomes possible for a long series of abstract thoughts to create substitute-images in the manifest dream which do indeed serve the purpose of concealment. This

is how our picture-puzzles are made up. The source of the semblance of wit which goes with this type of representation is a special question which we need not touch on here.

There is a fourth kind of relation between the manifest and the latent elements which I will say nothing about until the time comes for it in my account of our technique. Even then I shall not have given you a full list of these possible relations, but we shall have sufficient for our purpose.

Now do you think you can summon up courage to venture on the interpretation of a whole dream? Let us see whether we are adequately equipped for the task. I shall not, of course, choose one of the most obscure, but all the same it shall be one which shows the characteristics of dreams in a well-marked form.

A young woman who had already been married for a number of years dreamt as follows: *She was at the theatre with her husband, and one side of the stalls was quite empty. Her husband told her that Elise L and her fiancé also wanted to come, but could only get bad seats, three for a florin and a half, and of course they could not take those. She replied that in her opinion they did not lose much by that.*

The first thing stated by the dreamer is that the occasion giving rise to the dream is alluded to in the manifest content: her husband had really told her that Elise L, an acquaintance of about her own age, had become engaged, and the dream is the reaction to this piece of news. We know already that in many dreams it is easy to point to some such occasion occurring on the day before, and that this is often traced by the dreamer without any difficulty. This dreamer supplies us with further information of the same sort about other elements in the manifest dream. To what did she trace the detail of one side of the stalls being empty? It was an allusion to a real occurrence of the week before, when she had meant to go to a certain play and had therefore booked seats *early*, so early that she had to pay extra for the tickets. On entering the theatre it was evident that her anxiety had been quite superfluous, for one side of the stalls was almost empty. It would have been time enough if she had bought the tickets on the actual day of the performance and her husband did not fail to tease her about having been in *too great a hurry*. Next, what about the one florin and a half (1 fl. 50)? This was traced to quite another context which had nothing to do with the former, but it again refers

<sup>1</sup> This example has been altered in translation to bring in the play upon words in English.—TR.

<sup>2</sup> See note on preceding example.—T.

to some news received on the previous day. Her sister-in-law had had a present of 150 florins from her husband and had rushed off *in a hurry*, like a silly goose, to jeweller's shop and spent it all on a piece of jewellery. What about the number three? She knew nothing about that unless this idea could be counted an association, that the engaged girl, Elise L, was only three months younger than she herself who had been married ten years. And the absurdity of taking three tickets for two people? She had nothing to say to this and refused to give any more associations or information whatever.

Nevertheless, her few associations have provided us with so much material that it is possible to discover the latent dream-thoughts. We are struck by the fact that in her statements references to time are noticeable at several points, which form a common basis for the different parts of this material. She had got the theatre tickets *too soon*, taken them in *too great a hurry*, so that she had to pay extra for them; in the same way her sister-in-law had *hurried* off to the jeweller's with her money to buy an ornament with it, as though she might *miss something*. If the strongly emphasized points: *too early*, *too great a hurry*, are connected with the occasion for the dream (namely, the news that her friend, only three months *younger* than herself, had now found a good husband after all) and with the criticism expressed in her asperity about her sister-in-law, that it was *folly* to be so precipitate, there occurs to us almost spontaneously the following construction of the latent dream-thoughts, for which the manifest dream is a highly distorted substitute:

"It was really *foolish* of me to be in such a hurry to marry! Elise's example shows me that I too could have found a husband later on." (The over-haste is represented by her own conduct in buying the tickets and that of her sister-in-law in buying the jewellery. Going to the theatre is substituted for getting married.) This would be the main thought; perhaps we may go on, though with less certainty because the analysis in these passages ought not to be unsupported by statements of the dreamer: "And I might have had one a hundred times better for the money!" (150 florins is 100 times more than one florin and a half.) If we may substitute the dowry for the money, it would mean that the husband is bought with the dowry: both the jewellery and the bad seats would stand for the husband. It would be still

more desirable if we could see some connection between the element *three tickets* and a husband; but our knowledge does not as yet extend to this. We have only found out that the dream expresses *depreciation* of her own husband and regret at having *married so early*.

In my opinion we shall be more surprised and confused by the result of this our first attempt at dream-interpretation than satisfied with it. Too many ideas force themselves upon us at once, more than as yet we can master. We see already that we shall not come to the end of what the interpretation of this dream can teach us. Let us immediately single out those points in which we can definitely see some new knowledge.

In the first place: we note that in the latent thoughts the chief emphasis falls upon the element of hurry; in the manifest dream that is exactly a feature about which we find nothing. Without analysis we could have had no suspicion that this thought entered in at all. It seems possible, therefore, that precisely the main point round which the unconscious thoughts centre does not appear in the manifest dream at all. This fact must radically change the impression made upon us by the whole dream. In the second place: in the dream there is a nonsensical combination of ideas (three for one florin and a half); in the dream-thoughts we detect the opinion: "It was folly (to marry so early)." Can one reject the conclusion that this thought, "It was *folly*," is represented by the introduction into the manifest dream of an *absurd* element? In the third place: comparison shows us that the relation between manifest and latent elements is no simple one, certainly not of such a kind that a manifest always replaces a latent element. The relation between the two is of the nature of a relation between two different groups, so that a manifest element can represent several latent thoughts or a latent thought be replaced by several manifest elements.

As regards the meaning of the dream and the dreamer's attitude towards it, here again we might find many surprising things to say. The lady certainly admitted the interpretation, but she wondered at it; she had not been aware that she had such disparaging thoughts of her husband; she did not even know why she should so disparage him. So there is still much that is incomprehensible about it. I really think that as yet we are not properly equipped for interpreting a dream and that we need further instruction and preparation first.

## EIGHTH LECTURE

## CHILDREN'S DREAMS

WE HAD the impression that we had advanced too rapidly; let us therefore retrace our steps a little. Before we made our last experiment in which we tried to overcome the difficulty of dream-distortion by means of our technique, we said that it would be best to circumvent it by confining our attention to dreams in which distortion is absent or occurs only to a very slight extent, if there are any such dreams. In doing this, we are again departing from the actual course of development of our knowledge; for in reality it was only after consistently applying our method of interpretation, and after exhaustive analysis of dreams in which distortion occurred, that we became aware of the existence of those in which it is lacking.

The dreams we are looking for are met with in children: short, clear, coherent, and easy to understand, they are free from ambiguity and yet are unmistakable dreams. You must not think, however, that all dreams in children are of this type. Distortion in dreams begins to appear very early in childhood, and there are on record dreams of children between five and eight years old which already show all the characteristics of the dreams of later life. But, if you confine yourselves to those occurring in the period between the dawn of recognizable mental activity and the fourth or fifth year of life, you will discover a series which we should characterize as infantile, and, in the later years of childhood, you may find single dreams of the same type; indeed, even in grown up people under certain conditions dreams appear which in no way differ from the typically infantile.

Now from these children's dreams it is possible to obtain without any difficulty trustworthy information about the essential nature of dreams, which we hope will prove to be decisive and universally valid.

1. In order to understand these dreams there is no need for any analysis nor for the employment of any technique. It is not necessary to question the child who relates his dream. But we must know something about his life; in every instance there is some experience from the previous day which explains the dream. The dream is the mind's reaction in sleep to the experience of the previous day.

Let us consider some examples in order to base our further conclusions upon them:

(a) A boy of a year and ten months old had to present someone with a basket of cherries as

a birthday gift. He plainly did it very unwillingly, although he had been promised some of them for himself. The next morning he told his dream: "Hermann eaten all the cherries."

(b) A little girl of three and a quarter years went for the first time for a trip on the lake. When they came to land, she did not wish to leave the boat and cried bitterly; the time on the water had evidently gone too quickly for her. Next morning she said: "Last night I was sailing on the lake." We may probably infer that this trip lasted longer.

(c) A boy five and a quarter years old was taken on an excursion to the Escherntal near Hallstatt. He had heard that Hallstatt lay at the foot of the Dachstein and had shown great interest in that mountain. From the lodgings in Aussee there was a fine view of the Dachstein, and with a telescope it was possible to make out the Simony Hut on top. The child had repeatedly endeavoured to see the hut through the telescope, but nobody knew whether he had succeeded. The excursion began in a mood of joyful expectation. Whenever a new mountain came into sight, the little boy asked: "Is that the Dachstein?" Every time his question was answered in the negative he grew more out of spirits and presently became silent and refused to climb a little way up to the waterfall with the others. He was thought to be overtired, but the next morning he said quite happily: "Last night I dreamt that we were in the Simony Hut." So it was with this expectation that he had taken part in the excursion. The only detail he gave was one he had heard before: "You have to climb up steps for six hours."

These three dreams will be enough to give us all the information we need at this point.

2. We see that these childhood dreams are not meaningless; they are complete, comprehensible mental acts. Remember the medical verdict about dreams, which I told you, and the comparison with unskilled fingers wandering over the keys of the piano. You cannot fail to notice how sharply this conception is contradicted by the children's dreams I have quoted. Now it would surely be most extraordinary if a child were able to achieve the performance of complete mental acts during sleep, and the grown-up person in the same situation contented himself with spasmodic reactions. Besides, we have every reason for attributing better and deeper sleep to a child.

3. In these dreams there is no distortion and therefore they need no interpretation: the

manifest and the latent content is here identical. From this we conclude that *distortion is not essential to the nature of the dream*. I expect that this statement will take a weight off your minds. Nevertheless, closer consideration forces us to admit that even in these dreams distortion is present, though in a very slight degree, that there is a certain difference between the manifest content and the latent dream-thought.

4. The child's dream is a reaction to an experience of the previous day, which has left behind a regret, a longing, or an unsatisfied wish. *In the dream we have the direct, undisguised fulfilment of this wish*. Now consider our discussion as to the part played by the external or internal somatic stimuli as disturbers of sleep and begetters of dreams. We learnt certain quite definite facts on this point, but this explanation only held good in a small number of dreams. In these children's dreams there is nothing to indicate the influence of such somatic stimuli; we can make no mistake about it, for the dreams are perfectly comprehensible and each can easily be grasped as a whole. But we need not on that account give up our notion of the stimulus as causing the dream. We can only ask why we forget from the outset that there are *mental* as well as bodily sleep-disturbing stimuli; surely we know that it is these which are mainly responsible for disturbing the sleep of the grown-up person, in that they hinder him from bringing about in himself the mental condition essential for sleep, i.e., the withdrawal of interest from the outside world. He wishes not to have any interruption in his life; he would prefer to continue working at whatever occupies him, and that is the reason why he does not sleep. The mental stimulus which disturbs sleep is therefore for a child the unsatisfied wish, and his reaction to this is a dream.

5. This takes us by a very short step to a conclusion about the function of dreams. If dreams are the reaction to a mental stimulus their value must lie in effecting a discharge of the excitation so that the stimulus is removed and sleep can continue. We do not yet know how this discharge through the dream is effected dynamically, but we notice already that dreams are not disturbers of sleep (the accusation commonly brought against them), but are guardians and deliverers of it from disturbing influences. True, we are apt to think we should have slept better if we had not dreamed, but there we are wrong: the truth is that without

the help of the dream we should not have slept at all, and we owe it to the dream that we slept as well as we did. It could not help disturbing us a little, just as a policeman often cannot avoid making a noise when driving off disturbers of the peace who would wake us.

6. That dreams are brought about by a wish and that the content of the dream expresses this wish is one main characteristic of dreams. The other equally constant feature is that the dream does not merely give expression to a thought, but represents this wish as fulfilled, in the form of an hallucinatory experience. "I should like to sail on the lake," runs the wish which gives rise to the dream; the content of the dream itself is: "I am sailing on the lake." So that even in these simple dreams belonging to childhood there is still a difference between the latent and the manifest dream, and still a distortion of the latent dream-thought, *in the translation of the thought into an experience*. In interpreting a dream, we must first of all undo this process of alteration. If this is to be regarded as one of the most universal characteristics of all dreams, we then know how to translate the dream-fragment I quoted before: "I see my brother digging" does not mean "my brother is retrenching," but "I wish my brother would retrench, he is to retrench." Of the two universal characteristics here mentioned the second is obviously more likely to be acknowledged without opposition than the first.

It is only by extensive investigations that we can make sure that what produces the dream must always be a *wish* and cannot sometimes be a preoccupation, a purpose, or reproach; but the other characteristic remains unaffected, namely, that the dream does not merely reproduce this stimulus, but, by a kind of living it through, removes it, sets it aside, relieves it.

7. In connection with these characteristics of dreams we may take up again our comparison between dreams and errors. In the latter we distinguished between a disturbing tendency and one which is disturbed, the error being a compromise between the two. Dreams fall into the same category; the disturbed tendency can only, of course, be the tendency to sleep, while the disturbing tendency resolves itself into the mental stimulus which we may call the *wish* (clamouring for gratification), since at present we know of no other mental stimulus disturbing sleep. Here again the dream is the result of a compromise; we sleep, and yet we experience the satisfaction of a wish; we gratify a wish and at the same time continue to

sleep. Each achieves part-success and part-failure.

8. You will remember that at one point we hoped to find a path to an understanding of the problems presented by dreams in the fact that certain very transparent phantasy-formations are called *day-dreams*. Now these day-dreams are literally wish-fulfilments, fulfilments of ambitious or erotic wishes, which we recognize as such; they are, however, carried out in thought, and, however vividly imagined, they never take the form of hallucinatory experiences. Here, therefore, the less certain of the two main characteristics of the dream is retained, whereas the other, to which the condition of sleep is essential and which cannot be realized in waking life, is entirely lacking. So in language we find a hint that a wish-fulfilment is a main characteristic of dreams. And further, if the experience we have in dreams is only another form of imaginative representation, a form which becomes possible under the peculiar conditions of the sleeping state—a *nocturnal day-dream*, as we might call it—we understand at once how it is that the process of dream-formation can abrogate the stimulus operating at night and can bring gratification; for day-dreaming also is a mode of activity closely linked up with gratification, which is in fact the only reason why people practise it.

Again, there are other linguistic expressions, besides this, which imply the same thing. We are familiar with the proverbs: "The pig dreams of acorns and the goose of maize." "What do chickens dream of? Of millet." The proverb, you see, goes even lower in the scale than we do, beyond the child to the animal, and asserts that the content of dreams is the satisfaction of a want. And there are many phrases which seem to point to the same thing: we say "as beautiful as a dream." "I should never have dreamt of such a thing." "I never imagined that in my wildest dreams." Here colloquial speech is clearly partial in its judgment. Of course there are also anxiety-dreams and dreams the content of which is painful or indifferent, but these have not given rise to any special phrases. We do indeed speak of *bad* dreams, but by a *dream* pure and simple common usage always understands some sort of exquisite wish-fulfilment. Nor is there any proverb which attempts to assert that pigs or geese dream of being slaughtered!

It is, of course, inconceivable that this wish-fulfilling character of dreams should have escaped the notice of writers on the subject. On

the contrary, they have very often remarked upon it; but it has not occurred to any of them to recognize this characteristic as universal, and to take it as the key to the explanation of dreams. We can easily imagine what may have deterred them, and later we will discuss the question.

Now see how much information we have gained, and that with hardly any trouble, from our study of children's dreams! We have learnt that the function of dreams is to protect sleep; that they arise out of two conflicting tendencies, of which the one, the desire for sleep, remains constant, whilst the other endeavours to satisfy some mental stimulus; that dreams are proved to be mental acts, rich in meaning; that they have two main characteristics, i.e., they are wish-fulfilments and hallucinatory experiences. And meanwhile we could almost have forgotten that we were studying psycho-analysis. Apart from the connection we have made between dreams and errors our work has not borne any specific stamp. Any psychologist knowing nothing of the assumptions of psycho-analysis could have given this explanation of children's dreams. Why has no one done so?

If only all dreams were of the infantile type the problem would be solved and our task already achieved, and that without questioning the dreamer, referring to the unconscious or having recourse to the process of free association. Clearly it is in this direction that we must continue our work. We have already repeatedly found that characteristics alleged to be universally valid have afterwards proved to hold good only for a certain kind and a limited number of dreams. So the question we now have to decide is whether the common characteristics revealed by children's dreams are any more stable than these, and whether they hold also for those dreams whose meaning is not obvious and in whose manifest content we can recognize no reference to a wish remaining from the day before. Our idea is that these other dreams have undergone a good deal of distortion and on that account we must refrain from immediate judgment. We suspect too that to unravel this distortion we shall need the help of psycho-analytic technique, which we could dispense with while learning, as we have just now done, the meaning of children's dreams.

There is yet one other class of dreams at least in which no distortion is present and which, like children's dreams, we easily recognize to be wish-fulfilments. These are dreams which are occasioned all through life by im-

perative physical needs—hunger, thirst, sexual desire—and are wish-fulfilments in the sense of being reactions to internal somatic stimuli. Thus I have on record the dream of a little girl, one year and seven months old, which consisted of a kind of menu, together with her name (Anna F . . . , strawberries, bilberries, egg, pap), the dream being a reaction to a day of fasting, enforced on account of indigestion due to eating the fruit which appeared twice in the dream. At the same time her grandmother—their combined ages totalled seventy—was obliged, owing to a floating kidney, to go without food for a day and dreamt that night that she had been invited out and had had the most tempting delicacies set before her. Observations on prisoners who are left to go hungry, and on people who suffer privations whilst traveling or on expeditions, show that in these circumstances they regularly dream about the satisfaction of their wants. Thus Otto Nordenskjöld in his book on the Antarctic (1904) tells us of the band of men in whose company he spent the winter (Vol. I, p. 336): “Our dreams showed very clearly the direction our thoughts were taking. Never had we dreamt so frequently and so vividly as at that time. Even those of our comrades who usually dreamt but rarely had now long stories to tell in the mornings when we exchanged our latest experiences in this realm of phantasy. All the dreams were about that outside world now so far away, but often they included a reference to our condition at the time . . . eating and drinking were, incidentally, the pivot on which our dreams most often turned. One of us, who was particularly good at going out to large dinners in his sleep, was delighted when he could tell us in the morning that he had had a three-course dinner. Another dreamt of tobacco, whole mountains of tobacco; another of a ship which came full sail over the water, at last clear of ice. Yet another dream deserves mention: the postman came with the letters and gave a long explanation of why they were so late; he said he had made a mistake in delivering them, and had had great trouble in getting them back again. Of course, things even more impossible occupied our minds in sleep, but the lack of imagination in almost all the dreams which I dreamt myself or heard the others tell was quite striking. It would certainly be of great psychological interest if we had a record of all these dreams. You can imagine how we longed for sleep, when it offered each one of us all that he most eagerly desired.” Another quota-

tion, this time from Du Prel: “Mungo Park, when nearly dying of thirst on a journey in Africa, dreamt continually of the well-watered hills and valleys of his home. So Trenck, tormented with hunger in the redoubt at Magdebourg, saw himself in his dream surrounded by sumptuous meals; and George Back, who took part in Franklin’s first expedition, when on the point of dying of hunger owing to their terrible privations, dreamt regularly of abundant food to eat.”

Anyone who has made himself thirsty at night by eating highly seasoned dishes at supper is likely to dream of drinking. Of course it is not possible to relieve acute hunger or thirst by dreaming; in that case we awake thirsty and are obliged to drink real water. The service of the dream is here of little practical account, but it is none the less clear that it was called up for the purpose of protecting sleep from the stimulus impelling us to wake up and act. Where the intensity of the desire is less, *satisfaction-dreams* do often answer the purpose.

In the same way, when the stimulus is that of sexual desire, the dream provides satisfaction, but of a kind which shows peculiarities worthy of mention. Since it is a characteristic of the sexual impulse that it is a degree less dependent on its object than are hunger and thirst, the satisfaction in a pollution-dream can be real; and, in consequence of certain difficulties in the relation to the object (which will be discussed later), it particularly often happens that the real satisfaction is yet connected with a vague or distorted dream-content. This peculiarity of pollution-dreams makes them, as O. Rank has observed, suitable objects for the study of dream-distortion. Moreover, with adults, dreams of desire usually contain besides the satisfaction something else, springing from a purely mental source and requiring interpretation if it is to be understood.

We do not maintain, by the way, that wish-fulfilment dreams of the infantile type occur in adults solely as reactions to the imperative desires I have mentioned. We are equally familiar with short clear dreams of this type, occasioned by certain dominating situations and unquestionably produced by mental stimuli. For example, there are *impatience-dreams* in which someone making preparations for a journey, for a theatrical performance in which he is specially interested, or for a lecture or a visit, has his expectations prematurely realized in a dream, and finds himself the night before the actual experience already at his journey’s

end, at the theatre, or talking to the friend he is going to visit. Or again, there is the *comfort-dream*, rightly so-called, in which someone who wants to go on sleeping dreams that he has already got up, that he is washing, or is at school, while all the time he is really continuing his sleep, meaning that he would rather dream of getting up than do so in reality. In these dreams the desire for sleep, which we have recognized as regularly participating in dream-formation, expresses itself plainly and appears as their actual originator. The need for sleep ranks itself quite rightly with the other great physical needs.

I would refer you at this point to . . . a picture by Schwind in the Schack Gallery at Munich and would ask you to notice how correctly the artist has realized the way in which a dream arises out of a dominating situation. The picture is called *The Prisoner's Dream*, and the subject of the dream must undoubtedly be his escape. It is a happy thought that the prisoner is to escape by the window, for it is through the window that the ray of light has entered and roused him from sleep. The gnomes standing one above the other no doubt represent the successive positions he would have to assume in climbing up to the window; and, if I am not mistaken and do not attribute too much intentional design to the artist, the features of the gnome at the top, who is filing the grating through (the very thing the prisoner himself would like to do), resemble the man's own.

I have said that in all dreams, other than those of children and such as conform to the infantile type, we encounter the obstacle of distortion. We cannot immediately say whether they too are wish-fulfilments, as we are inclined to suppose, nor can we guess from their manifest content in what mental stimulus they originate, or prove that they, like the others, endeavour to remove or relieve the stimulus. They must, in fact, be interpreted, i.e., translated; the process of distortion must be reversed, and the manifest content replaced by the latent thought, before we can make any definite pronouncement whether what we have found out about infantile dreams may claim to hold good for all dreams alike.

## NINTH LECTURE

### THE DREAM-CENSORSHIP

Our study of children's dreams has taught us how dreams originate, what their essential

character is, and what their function. Dreams are the means of removing, by hallucinatory satisfaction, mental stimuli that disturb sleep. It is true that with the dreams of adults we have been able to explain one group only, those which we termed dreams of the infantile type. We do not yet know how it may be with others, neither do we understand them. The result we have arrived at already is one, however, of which the significance is not to be underestimated. Every time that we fully understand a dream it proves to be a wish-fulfilment; and this coincidence cannot be accidental or unimportant.

Dreams of another type are assumed by us to be distorted substitutes for an unknown content, which first of all has to be traced; we have various grounds for this assumption, amongst others the analogy to our conception of errors. Our next task is to investigate and understand this *dream-distortion*.

It is dream-distortion which makes dreams seem strange and incomprehensible. There are several things we want to know about it: first, whence it comes (its dynamics), secondly, what it does, and finally, how it does it. Further, we can say that distortion is the production of the *dream-work*. Let us describe the dream-work and trace out the forces in it.

Now let me tell you a dream recorded by a lady well-known in psycho-analytical circles,<sup>1</sup> who said that the dreamer was an elderly woman, highly cultivated and held in great esteem. The dream was not analysed and our informant observed that for psycho-analysts it needed no interpreting. Nor did the dreamer herself interpret it, but she criticized it and condemned it in such a way as though she knew what it meant. "Imagine," she said, "such abominable nonsense being dreamt by a woman of fifty, whose only thought day and night is concern for her child."

I will now tell you the dream, which is about "love service in war-time."<sup>2</sup> "She went to the First Military Hospital and said to the sentinel at the gate that she must speak to the physician-in-chief (giving a name which she did not know), as she wished to offer herself for service in the hospital. In saying this, she emphasized the word service in such a way that the sergeant at once perceived that she was speaking of 'love service.' As she was an old lady, he let her pass after some hesitation,

<sup>1</sup> Frau Dr. von Hug-Hellmuth.

<sup>2</sup> *Liebesdienst* = "love service," a popular expression adapted from "military service."—TR.

but instead of finding the chief physician, she came to a large gloomy room, where a number of officers and army doctors were standing or sitting around a long table. She turned to a staff doctor and told him her proposal; he soon understood her meaning. The words she said in her dream were: 'I and countless other women and girls of Vienna are ready for the soldiers, officers or men, to . . .' This ended in a murmur. She saw, however, by the half-embarrassed, half-malicious expressions of the officers that all of them grasped her meaning. The lady continued: 'I know our decision sounds odd, but we are in bitter earnest. The soldier on the battlefield is not asked whether he wishes to die or not.' There followed a minute of painful silence; then the staff doctor put his arm round her waist and said: 'Madam, supposing it really came to this, that . . . (murmur).'

She withdrew herself from his arm, thinking: 'They are all alike,' and replied: 'Good heavens, I am an old woman and perhaps it won't happen to me. And one condition must be observed: age must be taken into account, so that an old woman and a young lad may not . . . (murmur); that would be horrible.' The staff doctor said: 'I quite understand'; but some of the officers, amongst them one who as a young man had made love to her, laughed loudly, and the lady asked to be taken to the physician-in-chief, whom she knew, so that everything might be put straight. It then struck her, to her great consternation, that she did not know his name. The staff doctor, however, with the utmost respect and courtesy, showed her the way to the second floor, up a very narrow iron spiral staircase leading direct from the room where they were to the upper storeys. As she went up, she heard an officer say: 'That is a tremendous decision, no matter whether she is young or old; all honour to her!' With the feeling that she was simply doing her duty, she went up an endless staircase."

This dream was repeated twice within a few weeks, with alterations here and there which, as the lady remarked, were quite unimportant and entirely meaningless.

The way in which this dream progresses corresponds to the course of a day-dream; there are only a few places where an interruption occurs, and many individual points in its content might have been cleared up by enquiry: this, however, as you know, was not undertaken. But the most striking and to us the most interesting thing about it is the occurrence of many gaps, not in the recollection, but

in the content. In three places the latter is, as it were, blotted out; where these gaps occur the speeches are interrupted by a *murmur*. As we did not analyse the dream, we have, strictly speaking, no right to say anything about its meaning; but there are certain indications from which we may draw conclusions, e.g., the words *love service*; and, above all, the broken speeches immediately preceding the murmurs require completion of a kind which admits of only one construction. If we do so complete them a phantasy results, in which the content is that the dreamer is ready at the call of duty to offer herself to gratify the sexual needs of the troops, irrespective of rank. This is certainly shocking, a model of a shamelessly libidinous phantasy, but—the dream says nothing about this. Just where the context demands this confession, there is in the manifest dream an indistinct murmur: something has been lost or suppressed.

I hope you recognize how obvious is the inference that it is just the shocking nature of these passages which has led to their suppression. Now where will you find a parallel to what has taken place here? In these times you have not far to seek. Take up any political paper and you will find that here and there in the text something is omitted and in its place the blank white of the paper meets your eye: you know that this is the work of the press censor. Where these blank spaces occur, there originally stood something of which the official censors disapproved and which has been deleted on that account. You probably think it a pity, for that must have been the most interesting part, the *cream* of the news.

On other occasions the official censor has not dealt with the sentence in its completed form; for the writer, foreseeing which passages were likely to be objected to by the censor, has forestalled him by softening them down, making some slight modification or contenting himself with hints and allusions to what he really wants to write. In this case there are no blanks, but from the roundabout and obscure mode of expression you can detect the fact that, at the time of writing, the author had the censorship in mind.

Now keeping to this parallel we say that those speeches in the dream which were omitted or disguised by a murmur have also been sacrificed to some form of censorship. We actually use the term DREAM-CENSORSHIP, and ascribe part of the distortion to its agency. Wherever there are gaps in the manifest dream we know

that the censorship is responsible; and indeed we should go further and recognize that wherever, amongst other more clearly defined elements, one appears which is fainter, more indefinite or more dubious in recollection, it is evidence of the work of the censorship. It is, however, seldom that it takes a form so undisguised, so naïve, as we might say, as it does in the case of the dream about *love service*; far more often the censorship makes itself felt in the second way I mentioned: by effecting modifications, hints, and allusions in place of the true meaning.

There is a third way in which the dream-censorship works, to which the ordinances of the press censorship supply no parallel; but it happens that I can demonstrate to you this particular mode of activity on the part of the dream-censorship in the only dream hitherto analysed by us. You will remember the dream of the "three bad theatre-tickets, costing one florin and a half." In the latent thoughts underlying this dream, the element *too great a hurry, too early* was in the foreground; the meaning was: "It was folly to marry so *early*, it was foolish also to take the tickets so *early*, it was ridiculous of the sister-in-law to spend her money so *hurriedly* on a piece of jewellery." Nothing of this central element of the dream-thoughts appeared in the manifest content, where everything was focussed on going to the theatre and taking tickets. By this displacement of the accent and regrouping of the dream-elements, the manifest content was made so unlike the latent thoughts that nobody would suspect the presence of the latter behind the former. This *displacement of accent* is one of the principal means employed in distortion, and it is this which gives the dream that character of strangeness which makes the dreamer himself reluctant to recognize it as the product of his own mind.

Omission, modification, regrouping of material—these then are the modes of the dream-censorship's activity and the means employed in distortion. The censorship itself is the originator, or one of the originators, of distortion, the subject of our present enquiry. Modification and alteration in arrangement are commonly included under the term *displacement*.

After these remarks on the activities of the dream-censorship, let us turn our attention to its dynamics. I hope you are not taking the expression *censorship* in too anthropomorphic a sense, picturing to yourselves the censor as a

stern little manikin or a spirit, who lives in a little chamber of the brain and there discharges the duties of his office; and neither must you localize it too exactly, so that you imagine a *brain-centre* whence there emanates a censorial influence, liable to cease with the injury or disappearance of that centre. For the present we may regard it merely as a useful term by which to express a dynamic relationship. This need not hinder us from asking what sort of tendencies exercise this influence and is it exercised upon; and further, we must not be surprised to discover that we have already come across the censorship, perhaps without recognizing it.

Indeed this has actually happened. Remember a surprising experience we had when we began to apply our method of free association: we discovered that our efforts to penetrate from the dream-element to the unconscious thought proper for which the former is a substitute encountered a certain *resistance*. The strength of this resistance, we said, varies, being sometimes enormous and at other times very slight. In the latter case we need only a few connecting-links for the work of interpretation; but where there is great resistance we are compelled to go through long chains of associations, which carry us far from the initial idea, and on the way we have to overcome all the difficulties of professedly critical objections to associations arising. That which we encountered as resistance in the work of interpretation we now meet again as the censorship in the dream-work: the resistance is simply the censorship objectified; it proves to us that the power of the censorship is not exhausted in effecting distortion, being thereby extinguished, but that the censorship remains as a permanent institution, the object of which is to maintain the distortion when once it has been achieved. Moreover, just as the strength of the resistance encountered during interpretation varies with each element, so too the degree of distortion effected by the censorship is different for each element of a whole dream. A comparison of the manifest and the latent dream shows that certain latent elements are completely eliminated, others more or less modified, and others again appear in the manifest dream-content unaltered or perhaps even intensified.

Our purpose, however, was to find out which are the tendencies exercising the censorship and upon which tendencies it is exercised. Now this question, which is fundamental for the understanding of dreams and perhaps of human life altogether, is easy to answer when we survey

the series of dreams which we have succeeded in interpreting. The tendencies which exercise the censorship are those which are acknowledged by the waking judgment of the dreamer and with which he feels himself to be at one. You may be sure that when you repudiate any correctly found interpretation of a dream of your own, you do so from the same motives as cause the censorship to be exercised and distortion effected, and make interpretation necessary. Consider the dream of our lady of fifty: her dream, although it had not been interpreted, struck her as shocking and she would have been even more outraged if Dr. von Hug-Hellmuth had told her something of its unmistakable meaning; it was just this attitude of condemnation which caused the offensive passages in the dream to be replaced by a murmur.

Those tendencies against which the dream-censorship is directed must next be described from the point of view of this inner critical standard. When we do this, we can only say that they are invariably of an objectionable nature, offensive from the ethical, aesthetic or social point of view, things about which we do not dare to think at all, or think of only with abhorrence. Above all are these censored wishes, which in dreams are expressed in a distorted fashion, manifestations of a boundless and ruthless egoism; for the dreamer's own ego makes its appearance in every dream, and plays the principal part, even if it knows how to disguise itself completely as far as the manifest content is concerned. This *sacro egoismo* of dreams is certainly not unconnected with the attitude of mind essential to sleep: the withdrawal of interest from the whole outside world.

The ego which has discarded all ethical bonds feels itself at one with all the demands of the sexual impulse, those which have long been condemned by our aesthetic training and those which are contrary to all the restraints imposed by morality. The striving for pleasure—the libido, as we say—chooses its objects unchecked by any inhibition, preferring indeed those which are forbidden: not merely the wife of another man, but, above all, the incestuous objects of choice which by common consent humanity holds sacred—the mother and the sister of men, the father and the brother of women. (Even the dream of our fifty-year-old lady is an incestuous one, the libido being unmistakably directed towards the son.) Desires which we believe alien to human nature show themselves powerful enough to give rise to dreams. Hate, too, rages unrestrainedly; wishes

for revenge, and death-wishes, against those who in life are nearest and dearest—parents, brothers and sisters, husband or wife, the dreamer's own children—are by no means uncommon. These censored wishes seem to rise up from a veritable hell; when we know their meaning, it seems to us in our waking moments as if no censorship of them could be severe enough. Dreams themselves, however, are not to blame for this evil content; you surely have not forgotten that their harmless, nay, useful, function is to protect sleep from disturbance. Depravity does not lie in the nature of dreams; in fact, you know that there are dreams which can be recognized as gratifying justifiable desires and urgent bodily needs. It is true that there is no distortion in these dreams, but then there is no need for it, they can perform their function without offending the ethical and aesthetic tendencies of the ego. Remember, too, that the degree of distortion is proportionate to two factors: on the one hand, the more shocking the wish that must be censored, the greater will be the distortion; but it is also great in proportion as the demands of the censorship are severe. Hence in a strictly brought up and prudish young girl, a rigid censorship will distort dream-excitations which we medical men would have recognized as permissible and harmless libidinous desires, and which the dreamer herself would judge in the same way ten years later.

Besides, we are still not nearly far enough advanced to allow ourselves to be outraged at the result of our work of interpretation. I think we still do not understand it properly; but first of all it is incumbent upon us to secure it against certain possible attacks. It is not at all difficult to detect weak points in it. Our interpretations were based on hypotheses which we adopted earlier: that there really is some meaning in dreams; that the idea of mental processes being unconscious for a time, which was first arrived at through hypnotic sleep, may be applied also to normal sleep; and that all associations are subject to determination. Now if, reasoning from these hypotheses, we had obtained plausible results in our dream-interpretation we should have been justified in concluding that these hypotheses were correct. But what if these discoveries are of the kind I have described? In that case, surely it seems natural to say: "These results are impossible, absurd, at the very least highly improbable, so there must have been something wrong about the hypotheses. Either the dream is, after all,

not a mental phenomenon, or there is nothing which is unconscious in our normal condition, or there is a flaw somewhere in our technique. Is it not simpler and more satisfactory to assume this than to accept all the abominable conclusions which we profess to have deduced from our hypotheses?"

Both! It is both simpler and more satisfactory, but not on that account necessarily more correct. Let us give ourselves time: the matter is not yet ripe for judgment. First of all, we can make the case against our interpretations even stronger. The fact that our results are so unpleasant and repellent would not perhaps weigh so very heavily with us; a stronger argument is the emphatic and well-grounded repudiation by dreamers of the wish-tendencies which we try to foist upon them after interpreting their dreams. "What," says one, "you want to prove to me from my dream that I grudge the money I have spent on my sister's dowry and my brother's education? But it is out of the question; I spend my whole time working for my brothers and sisters and my only interest in life is to do my duty by them, as, being the eldest, I promised our dead mother I would." Or a woman says: "I am supposed to wish that my husband were dead? Really that is outrageous nonsense! Not only is our married life very happy, though perhaps you won't believe that, but if he died I should lose everything I possess in the world." Or someone else will reply: "Do you mean to suggest that I entertain sexual desires towards my sister? The thing is ludicrous; she is nothing to me; we get on badly with one another, and for years I have not exchanged a word with her." We still might not be much impressed if these dreamers neither admitted nor denied the tendencies attributed to them; we might say that these are just the things of which they are quite unconscious. But when they detect in their own minds the exact opposite of such a wish as is interpreted to them, and when they can prove to us by their whole conduct in life that the contrary desire predominates, surely we must be nonplussed. Is it not about time now for us to discard our whole work of dream-interpretation as something which has led to a *reductio ad absurdum*?

No, not even now. Even this stronger argument falls to pieces when subjected to a critical attack. Assuming that unconscious tendencies do exist in mental life, the fact that the opposite tendencies predominate in conscious life goes to prove nothing. Perhaps there is room in

the mind for opposite tendencies, for contradictions, existing side by side; indeed, possibly the very predominance of the one tendency conditions the unconscious nature of the opposite. So the first objections raised only amount to the statement that the results of dream-interpretation are not simple and are very disagreeable. To the first charge we may reply that, however much enamoured of simplicity you may be, you cannot thereby solve one of the problems of dreams; you have to make up your mind at the outset to accept the fact of complicated relations. And, as regards the second point, you are manifestly wrong in taking the fact that something pleases or repels yourself as the motive for a scientific judgment. What does it matter if you do find the results of dream-interpretation unpleasant, or even mortifying and repulsive? *Ça n'empêche pas d'exister*<sup>1</sup>—as I, when a young doctor, heard my chief, Charcot, say in a similar case. We must be humble and put sympathies and antipathies honourably in the background if we would learn to know reality in this world. If a physicist could prove to you that organic life on the earth was bound to become extinct before long, would you venture to say to him also: "That cannot be so; I dislike the prospect too much." I think you would say nothing until another physicist came along and convicted the first of a mistake in his premises or his calculations. If you repudiate whatever is distasteful to you, you are repeating the mechanism of a dream structure rather than understanding and mastering it.

Perhaps, then, you will undertake to overlook the offensive nature of the censored dream-wishes and will fall back upon the argument that it is surely very improbable that we ought to concede so large a part in the human constitution to what is evil. But do your own experiences justify you in this statement? I will say nothing of how you may appear in your own eyes, but have you met with so much goodwill in your superiors and rivals, so much chivalry in your enemies and so little envy amongst your acquaintances, that you feel it incumbent on you to protest against the idea of the part played by egoistic baseness in human nature? Do you not know how uncontrolled and unreliable the average human being is in all that concerns sexual life? Or are you ignorant of the fact that all the excesses and aberrations of which we dream at night are crimes actually committed every day by men who are wide

<sup>1</sup> It won't kill you.—ED.

awake? What does psycho-analysis do in this connection but confirm the old saying of Plato that the good are those who content themselves with dreaming of what others, the wicked, actually do?

And now look away from individuals to the great war still devastating Europe: think of the colossal brutality, cruelty and mendacity which is now allowed to spread itself over the civilized world. Do you really believe that a handful of unprincipled place-hunters and corrupters of men would have succeeded in letting loose all this latent evil, if the millions of their followers were not also guilty? Will you venture, even in these circumstances, to break a lance for the exclusion of evil from the mental constitution of humanity?

You will accuse me of taking a one-sided view of war, and tell me that it has also called out all that is finest and most noble in mankind, heroism, self-sacrifice, and public spirit. That is true; but do not now commit the injustice, from which psycho-analysis has so often suffered, of reproaching it that it denies one thing because it affirms another. It is no part of our intention to deny the nobility in human nature, nor have we ever done anything to disparage its value. On the contrary, I show you not only the evil wishes which are censored but also the censorship which suppresses them and makes them unrecognizable. We dwell upon the evil in human beings with the greater emphasis only because others deny it, thereby making the mental life of mankind not indeed better, but incomprehensible. If we give up the one-sided ethical valuation then, we are sure to find the truer formula for the relation of evil to good in human nature.

Here the matter rests. We need not give up the results of our work of dream-interpretation, even though we cannot fail to find them strange. Perhaps later we shall be able to come nearer to understanding them by another path. For the present let us hold fast to this: dream-distortion is due to the censorship exercised, by certain recognized tendencies of the ego, over desires of an offensive character which stir in us at night during sleep. Obviously, when we ask ourselves why it is just at night that they appear and what is the origin of these reprehensible wishes, we find that there is still much to investigate and many questions to answer.

It would, however, be wrong if we neglected to give due prominence at this point to another result of these investigations. The dream-wishes

which would disturb our sleep are unknown to us; we first learn about them by dream-interpretation; they are therefore to be designated *unconscious at the moment* in the sense in which we have used the term. But we must recognize that they are also more than unconscious at the moment; for the dreamer denies them, as we have so frequently found, even after he has learnt of them through the interpretation of his dream. Here we have a repetition of the case which we first met with when interpreting the slip of the tongue "hic-cough," where the after-dinner speaker indignantly assured us that neither then nor at any time had he been conscious of any feeling of disrespect towards his chief. We ventured even then to doubt the value of this assertion and assumed instead that the speaker was permanently ignorant of the existence of this feeling within him. We meet with the same situation every time we interpret a dream in which there is a high degree of distortion, and this lends an added significance to our conception. We are now prepared to assume that there are processes and tendencies in mental life, of which we know nothing; have known nothing; have, for a very long time, perhaps even never, known anything about at all. This gives the term *unconscious* a fresh meaning for us: the qualification *at the moment* or *temporary* is seen to be no essential attribute, the term may also mean *permanently unconscious*, not merely *latent at the moment*. You see that later on we shall have to discuss this point further.

## TENTH LECTURE

### SYMBOLISM IN DREAMS

WE HAVE found out that the distortion in dreams which hinders our understanding of them is due to the activities of a censorship, directed against the unacceptable, unconscious wish-impulses. But of course we have not asserted that the censorship is the only factor responsible for the distortion, and as a matter of fact a further study of dreams leads to the discovery that there are yet other causes contributing to this effect; that is as much as to say, if the censorship were eliminated we should nevertheless be unable to understand dreams, nor would the manifest dream be identical with the latent dream-thoughts.

This other cause of the obscurity of dreams, this additional contribution to distortion, is revealed by our becoming aware of a gap in our technique. I have already admitted to you

that there are occasions when persons being analysed really have no associations to single elements in their dreams. To be sure, this does not happen so often as they declare that it does; in very many instances the association may yet be elicited by perseverance; but still there remain a certain number of cases where association fails altogether or, if something is finally extorted, it is not what we need. If this happens during psycho-analytic treatment, it has a certain significance which does not concern us here; but it also occurs in the course of interpretation of dreams in normal people, or when we are interpreting our own. When we are convinced, in such circumstances, that no amount of pressing is of any use, we finally discover that this unwelcome contingency regularly presents itself where special dream-elements are in question; and we begin to recognize the operation of some new principle, whereas at first we thought we had only come across an exceptional case in which our technique had failed.

In this way it comes about that we try to interpret these *silent* elements, and attempt to translate them by drawing upon our own resources. It cannot fail to strike us that we arrive at a satisfactory meaning in every instance in which we venture on this substitution, whereas the dream remains meaningless and disconnected as long as we do not resolve to use this method. The accumulation of many exactly similar instances then affords us the required certainty, our experiment having been tried at first with considerable diffidence.

I am presenting all this somewhat in outline, but that is surely allowable for purposes of instruction, nor is it falsified by so doing, but merely made simpler.

We arrive in this way at constant translations for a series of dream-elements, just as in popular books on dreams we find such translations for everything that occurs in dreams. You will not have forgotten that, when we employ the method of free association, such constant substitutions for dream-elements never make their appearance.

Now you will at once say that this mode of interpretation seems to you far more uncertain and open to criticism than even the former method of free association. But there is still something more to be said: when we have collected from actual experience a sufficient number of such constant translations, we eventually realize that we could actually have filled in these portions of the interpretation from our

own knowledge, and that they really could have been understood without using the dreamer's associations. How it is that we are bound to know their meaning is a matter which will be dealt with in the second half of our discussion.

We call a constant relation of this kind between a dream-element and its translation a *symbolic* one, and the dream-element itself a *symbol* of the unconscious dream-thought. You will remember that some time ago, when we were examining the different relations which may exist between dream-elements and the thoughts proper underlying them, I distinguished three relations: substitution of the part for the whole, allusion, and imagery. I told you then that there was a fourth possible relation, but I did not tell you what it was. This fourth relation is the symbolic, which I am now introducing; there are connected with it certain very interesting points for discussion, to which we will turn attention before setting forth our special observations on this subject. Symbolism is perhaps the most remarkable part of our theory of dreams.

First of all: since the relation between a symbol and the idea symbolized is an invariable one, the latter being as it were a translation of the former, symbolism does in some measure realize the ideal of both ancient and popular dream-interpretation, one from which we have moved very far in our technique. Symbols make it possible for us in certain circumstances to interpret a dream without questioning the dreamer, who indeed in any case can tell us nothing about the symbols. If the symbols commonly appearing in dreams are known, and also the personality of the dreamer, the conditions under which he lives, and the impressions in his mind after which his dream occurred, we are often in a position to interpret it straightaway; to translate it at sight, as it were. Such a feat flatters the vanity of the interpreter and impresses the dreamer; it is in pleasing contrast to the laborious method of questioning the latter. But do not let this lead you away: it is no part of our task to perform tricks nor is that method of interpretation which is based on a knowledge of symbolism one which can replace, or even compare with, that of free association. It is complementary to this latter, and the results it yields are only useful when applied in connection with the latter. As regards our knowledge of the dreamer's mental situation, moreover, you must reflect that you have not only to interpret dreams of people whom you know well; that, as a rule,

you know nothing of the events of the previous day which stimulated the dream; and that the associations of the person analysed are the very source from which we obtain our knowledge of what we call the mental situation.

Further, it is especially remarkable, particularly with reference to certain considerations upon which we shall touch later, that the most strenuous opposition has manifested itself again here, over this question of the existence of a symbolic relation between the dream and the unconscious. Even persons of judgment and standing, who in other respects have gone a long way with psycho-analysis, have renounced their adherence at this point. This behaviour is the more remarkable when we remember two things: first, that symbolism is not peculiar to dreams, nor exclusively characteristic of them; and, in the second place, that the use of symbolism in dreams was not one of the discoveries of psycho-analysis, although this science has certainly not been wanting in surprising discoveries. If we must ascribe priority in this field to anyone in modern times, the discoverer must be recognized in the philosopher K. A. Scherner (1861); psycho-analysis has confirmed his discovery, although modifying it in certain important respects.

Now you will wish to hear something about the nature of dream-symbolism and will want some examples. I will gladly tell you what I know, but I confess that our knowledge is less full than we could wish.

The symbolic relation is essentially that of a comparison, but not any kind of comparison. We must suspect that this comparison is subject to particular conditions, although we cannot say what these conditions are. Not everything with which an object or an occurrence can be compared appears in dreams as symbolic of it, and, on the other hand, dreams do not employ symbolism for anything and everything, but only for particular elements of latent dream-thoughts; there are thus limitations in both directions. We must admit also that we cannot at present assign quite definite limits to our conception of a symbol; for it tends to merge into substitution, representation, etc., and even approaches closely to allusion. In one set of symbols the underlying comparison may be easily apparent, but there are others in which we have to look about for the common factor, the *tertium comparationis* contained in the supposed comparison. Further reflection may then reveal it to us, or on the other hand it may remain definitely hidden from us. Again,

if the symbol is really a comparison, it is remarkable that this comparison is not exposed by the process of free association, and also that the dreamer knows nothing about it, but makes use of it unawares; nay, more, that he is actually unwilling to recognize it when it is brought to his notice. So you see that the symbolic relation is a comparison of a quite peculiar kind, the nature of which is as yet not fully clear to us. Perhaps some indication will be found later which will throw some light upon this unknown quantity.

The number of things which are represented symbolically in dreams is not great. The human body as a whole, parents, children, brothers and sisters, birth, death, nakedness—and one thing more. The only typical, that is to say, regularly occurring, representation of the human form as a whole is that of a *house*, as was recognized by Scherner, who even wanted to attribute to this symbol an overwhelming significance which is not really due to it. People have dreams of climbing down the front of a house, with feelings sometimes of pleasure and sometimes of dread. When the walls are quite smooth, the house means a man; when there are ledges and balconies which can be caught hold of, a woman. Parents appear in dreams as *emperor* and *empress*, *king* and *queen* or other exalted personages; in this respect the dream attitude is highly dutiful. Children and brothers and sisters are less tenderly treated, being symbolized by *little animals* or *vermin*. Birth is almost invariably represented by some reference to *water*: either we are falling into water or clambering out of it, saving someone from it or being saved by them, i.e., the relation between mother and child is symbolized. For dying we have setting out upon a *journey* or *travelling* by train, while the state of death is indicated by various obscure and, as it were, timid allusions; *clothes* and *uniforms* stand for nakedness. You see that here the dividing line between the symbolic and the allusive kinds of representation tends to disappear.

In comparison with the poverty of this enumeration, it cannot fail to strike us that objects and matters belonging to another range of ideas are represented by a remarkably rich symbolism. I am speaking of what pertains to the sexual life—the genitals, sexual processes and intercourse. An overwhelming majority of symbols in dreams are sexual symbols. A curious disproportion arises thus, for the matters dealt with are few in number, whereas the symbols for them are extraordinarily numerous,

so that each of these few things can be expressed by many symbols practically equivalent. When they are interpreted, therefore, the result of this peculiarity gives universal offense, for, in contrast to the multifarious forms of its representation in dreams, the interpretation of the symbols is very monotonous. This is displeasing to everyone who comes to know of it: but how can we help it?

As this is the first time in the course of these lectures that I have touched upon the sexual life, I owe you some explanation of the manner in which I propose to treat this subject. Psycho-analysis sees no occasion for concealments or indirect allusions, and does not think it necessary to be ashamed of concerning itself with material so important; it is of the opinion that it is right and proper to call everything by its true name, hoping in this way the more easily to avoid disturbing suggestions. The fact that I am speaking to a mixed audience can make no difference in this. No science can be treated in *usum delphini*, or in a manner adapted to school-girls; the women present, by appearing in this lecture-room, have tacitly expressed their desire to be regarded on the same footing as the men.

The male genital organ is symbolically represented in dreams in many different ways, with most of which the common idea underlying the comparison is easily apparent. In the first place, the sacred number *three* is symbolic of the whole male genitalia. Its more conspicuous and, to both sexes, more interesting part, the penis, is symbolized primarily by objects which resemble it in form, being long and upstanding, such as *sticks, umbrellas, poles, trees* and the like; also by objects which, like the thing symbolized, have the property of penetrating, and consequently of injuring, the body,—that is to say, pointed weapons of all sorts: *knives, daggers, lances, sabres*; fire-arms are similarly used: *guns, pistols and revolvers*, these last being a very appropriate symbol on account of their shape. In the anxiety-dreams of young girls, pursuit by a man armed with a knife or rifle plays a great part. This is perhaps the most frequently occurring dream-symbol: you can now easily translate it for yourselves. The substitution of the male organ by objects from which water flows is again easily comprehensible: *taps, watering-cans, or springs*; and by other objects which are capable of elongation, such as *pulley lamps, pencils which slide in and out of a sheath*, and so on. *Pencils, penholders, nail-files, hammers* and

other *implements* are undoubtedly male sexual symbols, based on an idea of the male organ which is equally easily perceived.

The peculiar property of this member of being able to raise itself upright in defiance of the law of gravity, part of the phenomenon of erection, leads to symbolic representation by means of *balloons, aeroplanes*, and, just recently, *Zeppelins*. But dreams have another, much more impressive, way of symbolizing erection; they make the organ of sex into the essential part of the whole person, so that the *dreamer himself flies*. Do not be upset by hearing that dreams of flying, which we all know and which are often so beautiful, must be interpreted as dreams of general sexual excitement, dreams of erection. One psycho-analytic investigator, P. Federn, has established the truth of this interpretation beyond doubt; but, besides this, Mourly Vold, a man highly praised for his sober judgment, who carried out the experiments with artificial postures of the arms and legs, and whose theories were really widely removed from those of psycho-analysis (indeed he may have known nothing about it), was led by his own investigations to the same conclusion. Nor must you think to object to this on the ground that women can also have dreams of flying; you should rather remind yourselves that the purpose of dreams is wish-fulfilment, and that the wish to be a man is frequently met with in women, whether they are conscious of it or not. Further, no one familiar with anatomy will be misled by supposing that it is impossible for a woman to realize this wish by sensations similar to those of a man, for the woman's sexual organs include a small one which resembles the penis, and this little organ, the clitoris, does actually play during childhood and in the years before sexual intercourse the same part as the large male organ.

Male sexual symbols less easy to understand are certain *reptiles and fishes*: above all, the famous symbol of the *serpent*. Why *hats and cloaks* are used in the same way is certainly difficult to divine, but their symbolic meaning is quite unquestionable. Finally, it may be asked whether the representation of the male organ by some other member, such as the *hand* or the *foot*, may be termed symbolic. I think the context in which this is wont to occur, and the female counterparts with which we meet, force this conclusion upon us.

The female genitalia are symbolically represented by all such objects as share with them the property of enclosing a space or are capa-

ble of acting as receptacles: such as *pits, hollows and caves*, and also *jars and bottles*, and *boxes* of all sorts and sizes, *chests, coffers, pockets*, and so forth. *Ships* too come into this category. Many symbols refer rather to the uterus than to the other genital organs: thus *cupboards, stoves* and, above all, *rooms*. Room symbolism here links up with that of houses, whilst *doors and gates* represent the genital opening. Moreover, material of different kinds is a symbol of woman—*wood, paper*, and objects made of these, such as *tables and books*. From the animal world, *snails and mussels* at any rate must be cited as unmistakable female symbols; of the parts of the body, the *mouth* as a representation of the genital opening, and, amongst buildings, *churches and chapels* are symbols of a woman. You see that all these symbols are not equally easy to understand.

The breasts must be included amongst the organs of sex; these, as well as the larger hemispheres of the female body, are represented by *apples, peaches and fruit* in general. The pubic hair in both sexes is indicated in dreams by *woods and thickets*. The complicated topography of the female sexual organs accounts for their often being represented by a *landscape* with rocks, woods and water, whilst the imposing mechanism of the male sexual apparatus lends it to symbolization by all kinds of complicated and indescribable *machinery*.

Yet another noteworthy symbol of the female genital organ is a *jewel case*, whilst *jewel* and *treasure* are used also in dreams to represent the beloved person,<sup>1</sup> and *sweetmeats* frequently stand for sexual pleasures. Gratification derived from a person's own genitals is indicated by any kind of *play*, including playing the piano. The symbolic representation of onanism by *sliding or gliding* and also by *pulling off a branch* is very typical. A particularly remarkable dream-symbol is the *falling out or extrac-tion of teeth*; the primary significance of this is certainly castration as a punishment for onanism. Special representations of sexual intercourse are less frequent in dreams than we should expect after all this, but we may mention in this connection rhythmical activities such as *dancing, riding and climbing*, and also *experiencing some violence*, e.g., being run over. To these may be added certain manual occupations, and of course being threatened with weapons.

You must not imagine that these symbols are either employed or translated quite simply: on

<sup>1</sup> Cf. sweetheart, sweetest.—TR.

all sides we meet with what we do not expect. For instance, it seems hardly credible that there is often no sharp discrimination of the different sexes in these symbolic representations. Many symbols stand for sexual organs in general, whether male or female: for instance, a *little child*, or a *little son or daughter*. At another time a symbol which is generally a male one may be used to denote the female sexual organ, or vice versa. This is incomprehensible until we have acquired some knowledge of the development of conceptions about sexuality amongst human beings. In many cases this ambiguity of the symbols may be apparent rather than real; and moreover, the most striking amongst them, such as weapons, pockets and chests, are never used bisexually in this way.

I will now give a brief account, beginning with the symbols themselves instead of with the objects symbolized, to show you from what spheres the sexual symbols have for the most part been derived, and I will add a few remarks relating particularly to those in which the attribute in common with the thing symbolized is hard to detect. An instance of an obscure symbol of this kind is the *hat*, or perhaps head-coverings in general; this usually has a masculine significance, though occasionally a feminine one. In the same way a *cloak* betokens a man, though perhaps sometimes without special reference to the organs of sex. It is open to you to ask why this should be so. A *tie*, being an object which hangs down and is not worn by women is clearly a male symbol, whilst *underlinen* and *linen* in general stands for the female. *Clothes and uniforms*, as we have heard, represent nakedness or the human form; *shoes and slippers* symbolize the female genital organs. *Tables and wood* we have mentioned as being puzzling, but nevertheless certain, female symbols; the *act of mounting ladders, steep places or stairs* is indubitably symbolic of sexual intercourse. On closer reflection we shall notice that the rhythmic character of this climbing is the point in common between the two, and perhaps also the accompanying increase in excitation—the shortening of the breath as the climber ascends.

We have already recognized that *landscapes* represent the female sexual organs; mountains and rocks are symbols of the male organ; *gardens*, a frequently occurring symbol of the female genitalia. *Fruit* stands for the breasts, not for a child. *Wild animals* denote human beings

whose senses are excited, and, hence, evil impulses or passions. *Blossoms and flowers* represent the female sexual organs, more particularly, in virginity. In this connection you will recollect that the blossoms are really the sexual organs of plants.

We already know how rooms are used symbolically. This representation may be extended, so that *windows and doors* (entrances and exits from rooms) come to mean the openings of the body; the fact of rooms being *open or closed* also accords with this symbolism: the *key*, which opens them, is certainly a male symbol.

This is some material for a study of dream-symbolism. It is not complete, and could be both extended and made deeper. However, I think it will seem to you more than enough; perhaps you may dislike it. You will ask: "Do I then really live in the midst of sexual symbols? Are all the objects round me, all the clothes I wear, all the things I handle, always sexual symbols and nothing else?" There really is good reason for surprised questions, and the first of these would be: How do we profess to arrive at the meaning of these dream-symbols, about which the dreamer himself can give us little or no information.

My answer is that we derive our knowledge from widely different sources: from fairy tales and myths, jokes and witticisms, from folklore, i.e., from what we know of the manners and customs, sayings and songs, of different peoples, and from poetic and colloquial usage of language. Everywhere in these various fields the same symbolism occurs, and in many of them we can understand it without being taught anything about it. If we consider these various sources individually, we shall find so many parallels to dream-symbolism that we are bound to be convinced of the correctness of our interpretations.

The human body is, we said, according to Scherner frequently symbolized in dreams by a house; by an extension of this symbolism, windows, doors and gates stand for the entrances to cavities in the body, and the façades may either be smooth or may have balconies and ledges to hold on to. The same symbolism is met with in colloquialisms; for instance, we speak of *a thatch of hair*, or *a tile hat*, or say of someone that he is not right *in the upper storey*. In anatomy, too, we speak of the openings of the body as its *portals*.

We may at first find it surprising that parents appear in our dreams as kings and emperors

and their consorts, but we have a parallel to this in fairy tales. Does it not begin to dawn upon us that the many fairy tales which begin with the words "Once upon a time there were a king and queen" simply mean: "Once upon a time there were a father and mother"? In family life the children are sometimes spoken of jestingly as *princes*, and the eldest son as the *crown prince*. The king himself is called the *father* of his people. Again, in some parts, little children are often playfully spoken of as *little animals*, e.g., in Cornwall, as *little toad*, or in Germany as *little worm*, and, in sympathizing with a child, Germans say *poor little worm*.

Now let us return to the house symbolism. When in our dreams we make use of the projections of houses as supports, does that not suggest a well-known, popular German saying, with reference to a woman with a markedly developed bust: "She has something for one to hold on to" (*Die hat etwas zum Anhalten*), whilst another colloquialism in the same connection is: "She has plenty of wood in front of her house" (*Die hat viel Holz vor dem Hause*), as though our interpretation were to be borne out by this when we say that wood is a female maternal symbol.

There is still something to be said on the subject of wood. It is not easy to see why wood should have come to represent a woman or mother, but here a comparison of different languages may be useful to us. The German word *Holz* (wood) is said to be derived from the same root as the Greek *ύλη*, which means *stuff*, raw material. This would be an instance of a process which is by no means rare, in that a general name for material has come finally to be applied to a particular material only. Now, in the Atlantic Ocean, there is an island named Madeira, and this name was given to it by the Portuguese when they discovered it, because at that time it was covered with dense forests; for in Portuguese the word for wood is *madeira*. But you cannot fail to notice that this *madeira* is merely a modified form of the Latin *materia*, which again signifies material in general. Now *materia* is derived from *mater* = mother, and the material out of which anything is made may be conceived of as giving birth to it. So, in the symbolic use of wood to represent woman or mother, we have a survival of this old idea.

Birth is regularly expressed by some connection with water: we are plunging into or emerging from water, that is to say, we give birth or are being born. Now let us not forget that this

symbol has a twofold reference to the actual facts of evolution. Not only are all land mammals, from which the human race itself has sprung, descended from creatures inhabiting the water—this is the more remote of the two considerations—but also every single mammal, every human being, has passed the first phase of existence in water—that is to say, as an embryo in the amniotic fluid of the mother's womb—and thus, at birth, emerged from water. I do not maintain that the dreamer knows this; on the other hand, I contend that there is no need for him to know it. He probably knows something else from having been told it as a child, but even this, I will maintain, has contributed nothing to symbol-formation. The child is told in the nursery that the stork brings the babies, but then where does it get them? Out of a pond or a well—again, out of the water. One of my patients who had been told this as a child (a little count, as he was then) afterwards disappeared for a whole afternoon, and was at last found lying at the edge of the castle lake, with his little face bent over the clear water, eagerly gazing to see whether he could catch sight of the babies at the bottom of the water.

In the myths of the births of heroes, a comparative study of which has been made by O. Rank—the earliest is that of King Sargon of Akkad, about 2800 B.C.—exposure in water and rescue from it play a major part. Rank perceived that this symbolizes birth in a manner analogous to that employed in dreams. When anyone in his dream rescues somebody from the water, he makes that person into his mother, or at any rate *a* mother; and in mythology, whoever rescues a child from water confesses herself to be its real mother. There is a well-known joke in which an intelligent Jewish boy, when asked who was the mother of Moses, answers immediately: "The Princess." He is told: "No, she only took him out of the water." "That's what *she* said," he replies, showing that he had hit upon the right interpretation of the myth.

Going away on a journey stands in dreams for dying; similarly, it is the custom in the nursery, when a child asks questions as to the whereabouts of someone who has died and whom he misses, to tell him that that person has "gone away." Here again, I deprecate the idea that the dream-symbol has its origin in this evasive reply to the child. The poet uses the same symbol when he speaks of the other side as "the undiscovered country from whose

bourne *no traveller* returns." Again, in everyday speech it is quite usual to speak of the "last journey," and everyone who is acquainted with ancient rites knows how seriously the idea of a journey into the land of the dead was taken, for instance, in ancient Egyptian belief. In many cases the *Book of the Dead* survives, which was given to the mummy, like a Baedeker, to take with him on the last journey. Since burial grounds have been placed at a distance from the houses of the living, the last journey of the dead has indeed become a reality.

Nor does sexual symbolism belong only to dreams. You will all know the expression *a baggage* as applied contemptuously to a woman, but perhaps people do not know that they are using a genital symbol. In the New Testament we read: "The woman is the weaker vessel." The sacred writings of the Jews, the style of which so closely approaches that of poetry, are full of expressions symbolic of sex, which have not always been correctly interpreted and the exegesis of which, e.g., in the Song of Solomon, has led to many misunderstandings.<sup>1</sup> In later Hebrew literature the woman is very frequently represented by a house, the door standing for the genital opening; thus a man complains, when he finds a woman no longer a virgin, that "he has found the door open." The symbol *table* for a woman also occurs in this literature; the woman says of her husband "I spread the table for him, but he overturned it." Lame children are said to owe their infirmity to the fact that the man "overturned the table." I quote here from a treatise by L. Levy in Brünn: *Sexual Symbolism in the Bible and the Talmud*.

That ships in dreams signify women is a belief in which we are supported by the etymologists, who assert that *ship* (*Schiff*) was originally the name of an earthen vessel and is the same word as *Schaff* (a tub or wooden vessel). That an oven stands for a woman or the mother's womb is an interpretation confirmed by the Greek story of Periander of Corinth and his wife Melissa. According to the version of Herodotus, the tyrant adjured the shade of his wife, whom he had loved passionately but had murdered out of jealousy, to tell him something about herself, whereupon the dead woman identified herself by reminding him that he, Periander, "had put his bread into a cold oven," thus expressing in a disguised form a circumstance of which everyone else was ignorant. In the *Anthropophyteia*, edited by F. S. Kraus, a work which is an indispensable textbook on

<sup>1</sup> e. g., Song of Sol. 8. 10.

everything concerning the sexual life of different peoples, we read that in a certain part of Germany people say of a woman who is delivered of a child that "her oven has fallen to pieces." The kindling of fire and everything connected with this is permeated through and through with sexual symbolism, the flame always standing for the male organ, and the fire-place or the hearth for the womb of the woman.

If you have chanced to wonder at the frequency with which landscapes are used in dreams to symbolize the female sexual organs, you may learn from mythologists how large a part has been played in the ideas and cults of ancient times by *Mother Earth* and how the whole conception of agriculture was determined by this symbolism. The fact that in dreams a room represents a woman you may be inclined to trace to the German colloquialism by which *Frauenzimmer* (lit. woman's room) is used for *Frau*, that is to say, the human person is represented by the place assigned for her occupation. Similarly we speak of the *Porte*, meaning thereby the Sultan and his government, and the name of the ancient Egyptian ruler, Pharaoh, merely means *great court*. (In the ancient Orient the courts between the double gates of the city were places of assembly, like the market-place in classical times.) But I think this derivation is too superficial, and it strikes me as more probable that the room came to symbolize woman on account of its property of enclosing within it the human being. We have already met with the house in this sense; from mythology and poetry we may take towns, citadels, castles and fortresses to be further symbols for women. It would be easy to decide the point by reference to the dreams of people who neither speak nor understand German. Of late years I have mainly treated foreign patients, and I think I recollect that in their dreams rooms stand in the same way for women, even though there is no word analogous to our *Frauenzimmer* in their language. There are other indications that symbolism may transcend the boundaries of language, a fact already maintained by the old dream-investigator, Schubert, in 1862. Nevertheless, none of my patients were wholly ignorant of German, so that I must leave this question to be decided by those analysts who can collect instances in other countries from persons who speak only one language.<sup>1</sup>

Amongst the symbols for the male sexual organ, there is scarcely one which does not appear in jests, or in vulgar or poetic phrases,

especially in the old classical poets. Here, however, we meet not only with such symbols as occur in dreams but also with new ones, e.g., the *implements* employed in various kinds of work, first and foremost, the *plough*. Moreover, when we come to male symbols, we tread on very extensive and much-contested ground which, in order not to waste time, we will avoid. I should just like to devote a few remarks to the one symbol which stands, as it were, by itself; I refer to the number *three*. Whether this number does not in all probability owe its sacred character to its symbolic significance is a question which we must leave undecided, but it seems certain that many tripartite natural objects, e.g., the clover-leaf, are used in coats-of-arms and as emblems on account of their symbolism. The so-called "French" lily with its three parts and, again, the *triskeles*, that curious coat-of-arms of two such widely separated islands as Sicily and the Isle of Man (a figure consisting of three bent legs projecting from a central point), are supposed to be merely disguised forms of the male sexual organ, images of which were believed in ancient times to be the most powerful means of warding off evil influences (*apotropaëa*); connected with this is the fact that the lucky *charms* of our own time may all be easily recognized as genital or sexual symbols. Let us consider a collection of such charms in the form of tiny silver pendants: a four-leaved clover, a pig, a mushroom, a horse-shoe, a ladder and a chimney-sweep. The four-leaved clover has taken the place of that with three leaves, which was really more appropriate for the purpose of symbolism; the pig is an ancient symbol of fruitfulness; the mushroom undoubtedly symbolizes the penis, there are mushrooms which derive their name from their unmistakable resemblance to that organ (*Phallus impudicus*); the horseshoe reproduces the contour of the female genital opening; while the chimney-sweep with his ladder belongs to this company because his occupation is one which is vulgarly compared with sexual intercourse. (Cf. *Anthropophyteia*.) We have learnt to recognize his ladder in dreams as a sexual symbol: expressions in language show what a completely sexual significance the word *steigen* (to mount) has, as in the phrases: *Den Frauen nachsteigen* (to run after women) and *ein alter Steiger* (an old roué). So, in French, where the word for *step* is *la marche*, we find the quite analogous expression for an old rake: *un vieux marcheur*. Probably the fact that with many of the larger animals sexual intercourse necessi-

<sup>1</sup> This is certainly so with English patients.—TR.

tates a mounting or *climbing upon* the female has something to do with this association of ideas.

Pulling off a branch to symbolize onanism is not only in agreement with vulgar descriptions of that act, but also has far-reaching parallels in mythology. But especially remarkable is the representation of onanism, or rather of castration as the punishment for onanism, by the falling-out or extraction of teeth; for we find in folk-lore a counterpart to this which could only be known to very few dreamers. I think that there can be no doubt that circumcision, a practice common to so many peoples, is an equivalent and replacement of castration. And recently we have learnt that certain aboriginal tribes in Australia practice circumcision as a rite to mark the attaining of puberty (at the celebration of the boy's coming of age), whilst other tribes living quite near have substituted for this practice that of knocking out a tooth.

I will end my account with these examples. They are only examples; we know more about this subject and you can imagine how much richer and more interesting a collection of this sort might be made, not by dilettanti like ourselves, but by real experts in mythology, anthropology, philology and folk-lore. We are forced to certain conclusions, which cannot be exhaustive, but nevertheless will give us plenty to think about.

In the first place, we are confronted with the fact that the dreamer has at his command a symbolic mode of expression of which he knows nothing, and does not even recognize, in his waking life. This is as amazing as if you made the discovery that your housemaid understood Sanscrit, though you know that she was born in a Bohemian village and had never learnt that language. It is not easy to bring this fact into line with our views on psychology. We can only say that the dreamer's knowledge of symbolism is unconscious and belongs to his unconscious mental life, but even this assumption does not help us much. Up till now we have only had to assume the existence of unconscious tendencies which are temporarily or permanently unknown to us; but now the question is a bigger one and we have actually to believe in unconscious knowledge, thought-relations, and comparisons between different objects, in virtue of which one idea can constantly be substituted for another. These comparisons are not instituted afresh every time, but are ready to hand, perfect for all time; this we infer from their

identity in different persons, even probably in spite of linguistic differences.

Whence is our knowledge of this symbolism derived? The usages of speech cover only a small part of it, whilst the manifold parallels in other fields are for the most part unknown to the dreamer; we ourselves had to collate them laboriously in the first instance.

In the second place, these symbolic relations are not peculiar to the dreamer or to the dream-work by which they are expressed, for we have discovered that the same symbolism is employed in myths and fairy tales, in popular sayings and songs, in colloquial speech and poetic phantasy. The province of symbolism is extraordinarily wide: dream-symbolism is only a small part of it; it would not even be expedient to attack the whole problem from the side of dreams. Many of the symbols commonly occurring elsewhere either do not appear in dreams at all or appear very seldom; on the other hand, many of the dream-symbols are not met with in every other department, but, as you have seen, only here and there. We get the impression that here we have to do with an ancient but obsolete mode of expression, of which different fragments have survived in different fields, one here only, another there only, a third in various spheres perhaps in slightly different forms. At this point I am reminded of the phantasy of a very interesting insane patient, who had imagined a *primordial language* (*Grundsprache*) of which all these symbols were survivals.

In the third place, it must strike you that the symbolism occurring in the other fields I have named is by no means confined to sexual themes, whereas in dreams the symbols are almost exclusively used to represent sexual objects and relations. This again is hard to account for. Are we to suppose that symbols originally of sexual significance were later employed differently and that perhaps the decline from symbolic to other modes of representation is connected with this? It is obviously impossible to answer these questions by dealing only with dream-symbolism; all we can do is to hold fast to the supposition that there is a specially close relation between true symbols and sexuality.

An important clue in this connection has recently been given to us in the view expressed by a philologist (H. Sperber, of Upsala, who works independently of psycho-analysis), that sexual needs have had the largest share in the origin and development of language. He says

that the first sounds uttered were a means of communication, and of summoning the sexual partner, and that, in the later development, the elements of speech were used as an accompaniment to the different kinds of work carried on by primitive man. This work was performed by associated efforts, to the sound of rhythmically repeated utterances, the effect of which was to transfer a sexual interest to the work. Primitive man thus made his work agreeable, so to speak, by treating it as the equivalent of and substitute for sexual activities. The word uttered during the communal work had therefore two meanings, the one referring to the sexual act, the other to the labour which had come to be equivalent to it. In time the word was dissociated from its sexual significance and its application confined to the work. Generations later the same thing happened to a new word with a sexual signification, which was then applied to a new form of work. In this way a number of root-words arose which were all of sexual origin but had all lost their sexual meaning. If the statement here outlined be correct, a possibility at least of understanding dream-symbolism opens out before us. We should comprehend why it is that in dreams, which retain something of these primitive conditions, there is such an extraordinarily large number of sexual symbols; and why weapons and tools in general stand for the male, and materials and things worked on for the female. The symbolic relations would then be the survival of the old identity in words; things which once had the same name as the genitalia could now appear in dreams as symbolizing them.

Further, our parallels to dream-symbolism may assist you to appreciate what it is in psycho-analysis which makes it a subject of general interest, in a way that was not possible to either psychology or psychiatry; psycho-analytic work is so closely intertwined with so many other branches of science, the investigation of which gives promise of the most valuable conclusions: with mythology, philology, folk-lore, folk psychology and the study of religion. You will not be surprised to hear that a publication has sprung from psycho-analytic soil, of which the exclusive object is to foster these relations. I refer to *Imago*, first published in 1912 and edited by Hans Sachs and Otto Rank. In its relation to all these other subjects, psycho-analysis has in the first instance given rather than received. True, analysis reaps the advantage of receiving confirmation of its own results, seemingly so strange,

again in other fields; but on the whole it is psycho-analysis which supplies the technical methods and the points of view, the application of which is to prove fruitful in these other provinces. The mental life of the human individual yields, under psycho-analytic investigation, explanations which solve many a riddle in the life of the masses of mankind or at any rate can show these problems in their true light.

I have still given you no idea of the circumstances in which we may arrive at the deepest insight into that hypothetical *primordial language*, or of the province in which it is for the most part retained. As long as you do not know this you cannot appreciate the true significance of the whole subject. I refer to the province of neurosis; the material is found in the symptoms and other modes of expression of nervous patients, for the explanation and treatment of which psycho-analysis was indeed devised.

My fourth point of view takes us back to the place from which we started and leads into the track we have already marked out. We said that even if there were no dream-censorship we should still find it difficult to interpret dreams, for we should then be confronted with the task of translating the symbolic language of dreams into the language of waking life. SYMBOLISM, then, is a second and independent factor in dream-distortion, existing side by side with the censorship. But the conclusion is obvious that it suits the censorship to make use of symbolism, in that both serve the same purpose: that of making the dream strange and incomprehensible.

Whether a further study of the dream will not introduce us to yet another contributing factor in the distortion, we shall soon see. But I must not leave the subject of dream-symbolism without once more touching on the puzzling fact that it has succeeded in rousing such strenuous opposition amongst educated persons, although the prevalence of symbolism in myth, religion, art and language is beyond all doubt. Is it not probable that, here again, the reason is to be found in its relation to sexuality?

## ELEVENTH LECTURE

### THE DREAM WORK

When you have successfully grasped the dream-censorship and symbolic representation, you will not, it is true, have mastered dream-distortion in its entirety, but you will nevertheless be in a position to understand most dreams.

To do so, you will make use of the two complementary methods: you will call up the dreamer's associations till you have penetrated from the substitute to the thought proper for which it stands, and you will supply the meaning of the symbols from your own knowledge of the subject. We will speak later of certain doubtful points which may arise in the process.

We can now return to a task which we attempted earlier with inadequate equipment, when we were studying the relations between dream-elements and the thoughts proper underlying them. We then determined the existence of four such main relations: substitution of the part for the whole, hints or allusions, symbolic connection, and plastic word-representation (images). We will now try to deal with this subject on a larger scale, by a comparison of the *manifest* dream-content as a whole with the *latent* dream as laid bare by our interpretation.

I hope you will never again confuse these two things. If you succeed in distinguishing between them, you will have advanced further towards an understanding of dreams than in all probability most of the readers of my *Interpretation of Dreams* have done. Let me again remind you that *the process by which the latent dream is transformed into the manifest dream is called THE DREAM-WORK*; while the reverse process, which seeks to progress from the manifest to the latent thoughts, is our work of interpretation; the work of interpretation therefore aims at demolishing the dream-work. In dreams of the infantile type in which the obvious wish-fulfilments are easily recognized, the process of dream-work has nevertheless been operative to some extent, for the wish has been transformed into a reality and, usually, the thoughts also into visual images. Here no interpretation is necessary; we only have to retrace both these transformations. The further operations of the dream-work, as seen in the other types of dreams, we call *dream-distortion*, and here the original ideas have to be restored by our interpretative work.

Having had the opportunity of comparing many dream-interpretations, I am in a position to give you a comprehensive account of the manner in which the dream-work deals with the material of the latent dream-thoughts. But please do not expect to understand too much: it is a piece of description which should be listened to quietly and attentively.

The first achievement of the dream-work is **CONDENSATION**; by this term we mean to con-

vey the fact that the content of the manifest dream is less rich than that of the latent thoughts, is, as it were, a kind of abbreviated translation of the latter. Now and again condensation may be lacking, but it is present as a rule and is often carried to a very high degree. It never works in the opposite manner, i.e., it never happens that the manifest dream is wider in range or richer in content than is the latent dream. Condensation is accomplished in the following ways: (1) certain latent elements are altogether omitted; (2) of many complexes in the latent dream only a fragment passes over into the manifest content; (3) latent elements sharing some common characteristic are in the manifest dream put together, blended into a single whole.

If you prefer to do so, you can reserve the term "condensation" for this last process, the effects of which are particularly easy to demonstrate. Taking your own dreams, you will be able without any trouble to recall instances of the condensation of different persons into a single figure. Such a composite figure resembles A in appearance, but is dressed like B, pursues some occupation which recalls C, and yet all the time you know that it is really D. The composite picture serves, of course, to lay special emphasis upon some characteristic common to the four people. And it is possible also for a composite picture to be formed with objects or places, as with persons, provided only that the single objects or places have some common attribute upon which the latent dream lays stress. It is as though a new and fugitive concept were formed, of which the common attribute is the kernel. From the superimposing of the separate parts which undergo condensation there usually results a blurred and indistinct picture, as if several photographs had been taken on the same plate.

The formation of such composite figures must be of great importance in the dream-work, for we can prove that the common properties necessary to their formation are purposely manufactured where at first sight they would seem to be lacking, as, for example, by the choice of some particular verbal expression for a thought. We have already met with instances of condensation and composite-formation of this sort; they played an important part in originating many slips of the tongue. You will remember the case of the young man who wished to "insort": a lady (*beleidigen* = "insult," *begleiten* = "escort," composite word *be-gleitigen*). Besides, there are jokes in which the

technique is traceable to condensation of this sort. Apart from this, however, we may venture to assert that this process is something quite unusual and strange. It is true that in many a creation of phantasy we meet with counterparts to the formation of the composite persons of our dreams, component parts which do not belong to one another in reality being readily united into a single whole by phantasy, as, for instance, in the centaurs and fabulous animals of ancient mythology or of Boecklin's pictures. *Creative phantasy* can, in fact, invent nothing new, but can only regroup elements from different sources. But the peculiar thing about the way in which the dream-work proceeds is this: its material consists of thoughts, some of which may be objectionable and disagreeable, but which nevertheless are correctly formed and expressed. The dream-work transmutes these thoughts into another form, and it is curious and incomprehensible that in this process of translation—of rendering them, as it were, into another script or language—the means of blending and combining are employed. The translator's endeavour in other cases must surely be to respect the distinctions observed in the text, and especially to differentiate between things which are similar but not the same; the dream-work, on the contrary, strives to condense two different thoughts by selecting, after the manner of wit, an ambiguous word which can suggest both thoughts. We must not expect to understand this characteristic straightaway, but it may assume great significance for our conception of the dream-work.

Although condensation renders the dream obscure, yet it does not give the impression of being an effect of the dream-censorship. Rather we should be inclined to trace it to mechanical or economic factors; nevertheless the censorship's interests are served by it.

What condensation can achieve is sometimes quite extraordinary: by this device it is at times possible for two completely different latent trains of thought to be united in a single manifest dream, so that we arrive at an apparently adequate interpretation of a dream and yet overlook a second possible meaning.

Moreover, one of the effects of condensation upon the relationship between the manifest and the latent dream is that the connection between the elements of the one and of the other nowhere remains a simple one; for by a kind of interlacing a manifest element represents simultaneously several latent ones and, conversely, a latent thought may enter into several

manifest elements. Again, when we come to interpret dreams, we see that the associations to a single manifest element do not commonly make their appearance in orderly succession; we often have to wait until we have the interpretation of the whole dream.

The dream-work, then, follows a very unusual mode of transcription for the dream-thoughts; not a translation, word for word, or sign for sign; nor yet a process of selection according to some definite rule, for instance, as though the consonants only of the words were reproduced and the vowels omitted; nor again what one might call a process of representation, one element being always picked out to represent several others. It works by a different and much more complicated method.

The second achievement of the dream-work is *DISPLACEMENT*. Fortunately here we are not breaking perfectly fresh ground; indeed, we know that it is entirely the work of the dream-censorship. Displacement takes two forms; first, a latent element may be *replaced*, not by a part of itself, but by something more remote, something of the nature of an allusion; and, secondly, the *accent* may be transferred from an important element to another which is unimportant, so that the centre of the dream is shifted as it were, giving the dream a foreign appearance.

Substitution by allusion is familiar to us in our waking thoughts also, but with a difference; for it is essential in the latter that the allusion should be easily comprehensible, and that the content of the substitute should be associated to that of the thought proper. Allusion is also frequently employed in wit, where the condition of association in content is dispensed with and replaced by unfamiliar external associations, such as similarity of sound, ambiguity of meaning, etc. The condition of comprehensibility, however, is observed: the joke would lose all its point if we could not recognize without any effort what is the actual thing to which the allusion is made. But in dreams allusion by displacement is unrestricted by either limitation. It is connected most superficially and most remotely with the element for which it stands, and for that reason is not readily comprehensible; and, when the connection is traced, the interpretation gives the impression of an unsuccessful joke or of a *forced*, far-fetched and *dragged* in explanation. The object of the dream-censorship is only obtained when it has succeeded in making it impossible to trace the thought proper back from the allusion.

Displacement of accent is not a legitimate device, if our object be the expression of thought; though we do sometimes admit it in waking life in order to produce a comic effect. I can to some extent convey to you the impression of confusion which then results, by reminding you of an anecdote, according to which there was in a certain village a smith who had committed a capital offence. The court decided that the smith was guilty; but, since he was the only one of his trade in the village and therefore indispensable, whereas there were three tailors living there, one of these three was hanged in his place!

The third achievement of the dream-work is the most interesting from the psychological point of view. It consists in the transformation of thoughts into *visual images*. Let us be quite clear that not everything in the dream-thoughts is thus transformed; much keeps its original form and appears also in the manifest dream as thought or knowledge, on the part of the dreamer; again, translation of them into visual images is not the only possible transformation of thoughts. But it is nevertheless the essential feature in the formation of dreams, and, as we know, this part of the dream-work is, if we except one other case, the least subject to variation; for single dream-elements, moreover, *plastic word-representation* is a process already familiar to us.

Obviously this achievement is by no means an easy one. In order to get some idea of its difficulty, imagine that you had undertaken to replace a political leading article in a newspaper by a series of illustrations; you would have to abandon alphabetic characters in favour of hieroglyphics. The people and concrete objects mentioned in the article could be easily represented, perhaps even more satisfactorily, in pictorial form; but you would expect to meet with difficulties when you came to the portrayal of all the abstract words and all those parts of speech which indicate relations between the various thoughts, e.g., particles, conjunctions, and so forth. With the abstract words you would employ all manner of devices: for instance, you would try to render the text of the article into other words, more unfamiliar perhaps, but made up of parts more concrete and therefore more capable of such representation. This will remind you of the fact that most abstract words were originally concrete, their original significance having faded; and therefore you will fall back on the original concrete meaning of these words wherever possible. So

you will be glad that you can represent the *possessing* of an object as a literal, physical *sitting upon* it (possess = *potis* + *sedeo*). This is just how the dream-work proceeds. In such circumstances you can hardly demand great accuracy of representation, neither will you quarrel with the dream-work for replacing an element which is difficult to reduce to pictorial form, such as the idea of breaking marriage vows, by some other kind of breaking, e.g., that of an arm or leg.<sup>1</sup> In this way you will to some extent succeed in overcoming the awkwardness of rendering alphabetic characters into hieroglyphs.

When you come to represent those parts of speech which indicate thought-relations, e.g., *because, therefore, but*, and so on, you have no such means as those described to assist you; so that these parts of the text must be lost, so far as your translation into pictorial form is concerned. Similarly, the content of the dream-

<sup>1</sup> Whilst correcting these pages, my eye happened to fall upon a newspaper paragraph which I reproduce here as affording unexpected confirmation of the above words.

## DIVINE RETRIBUTION

### A BROKEN ARM FOR A BROKEN MARRIAGE-VOW

Frau Anna M., the wife of a soldier in the reserve, accused Frau Clementine K. of unfaithfulness to her husband. In her accusation she stated that Frau K. had had an illicit relationship with Karl M. during her husband's absence at the front, while he was sending her as much as 70 crowns a month. Besides this, she had already received a large sum of money from her (Frau M.'s) husband, while his wife and children had to live in hunger and misery. Some of her husband's comrades had informed her that he and Frau K. had visited public-houses together and remained there drinking late into the night. The accused woman had once actually asked the husband of the accuser, in the presence of several soldiers, whether he would not soon leave his "old woman" and come to her, and the caretaker of the house where Frau K. lived had repeatedly seen the plaintiff's husband in Frau K.'s room, in a state of complete undress.

Yesterday, before a magistrate in the Leopoldstadt, Frau K. denied knowing M. at all: any intimate relations between them were out of the question, she said.

Albertine M., a witness, however, gave evidence of having surprised Frau K. in the act of kissing the accuser's husband.

M., who had been called as a witness in some earlier proceedings, had then denied any intimate relations with the accused. Yesterday, a letter was handed to the magistrate, in which the witness retracted his former denial and confessed that up to the previous June he had carried on illicit relations with Frau K. In the earlier proceedings he had denied his relations with the accused only because she had come to him: before the action came into court and begged him on her knees to save her and say nothing. "To-day," wrote the witness, "I feel compelled to lay a full confession before the court, for I have broken my left arm and regard this as God's punishment for my offence."

The judge decided that the penal offence had been committed too long ago for the action to stand, whereupon the accuser withdrew her accusation and the accused was discharged.

thoughts is resolved by the dream-work into its "raw material," consisting of objects and activities. You may be satisfied if there is any possibility of indicating somehow, by a more minute elaboration of the images, certain relations which cannot be represented in themselves. In a precisely similar manner, the dream-work succeeds in expressing much of the content of the latent thoughts by means of peculiarities in the *form* of the manifest dream, by its distinctness or obscurity, its division into various parts, etc. The number of parts into which a dream is divided corresponds as a rule with the number of its main themes, the successive trains of thought in the latent dream; a short preliminary dream often stands in an introductory or casual relation to the subsequent detailed main dream; whilst a subordinate dream-thought is represented by the interpolation into the manifest dream of a change of scene, and so on. The form of dreams, then, is by no means unimportant in itself, and itself demands interpretation. Several dreams in the same night often have the same meaning, and indicate an endeavour to control more and more completely a stimulus of increasing urgency. In a single dream, a specially difficult element may be represented by *doubling* it, i.e., by more than one symbol.

If we continue the comparison of dream-thoughts with the manifest dreams representing them, we discover in all directions things we should never have expected, e.g., that even nonsense and absurdity in dreams have their meaning; in fact, at this point the contrast between the medical and the psycho-analytic view of dreams becomes more marked than ever before. According to the medical view, the dream is absurd because while dreaming our mental activity has renounced its functions; according to our view, on the other hand, the dream becomes absurd when it has to represent a criticism implicit in the latent thoughts—the opinion: "It is absurd." The dream I told you, about the visit to the theatre ("three tickets for one florin and a half") is a good example of this: the opinion thus expressed was as follows: "It was *absurd* to marry so early."

Similarly, we find out when we interpret dreams what is the real meaning of the doubts and uncertainties, so frequently mentioned by dreamers, whether a certain element did actually appear in the dream, whether it was really this and not rather something else. As a rule, there is nothing in the latent thoughts corresponding with these doubts and uncertainties; they origi-

nate wholly through the operation of the censorship and are comparable to a not entirely successful attempt at erasure.

One of our most surprising discoveries is the manner in which *opposites* in the latent dream are dealt with by the dream-work. We know already that points of agreement in the latent material are replaced by condensation in the manifest dream. Now contraries are treated in just the same way as similarities, with a marked preference for expression by means of the *same* manifest element. An element in the manifest dream which admits of an opposite may stand simply for itself, or for its opposite, or for both together; only the sense can decide which translation is to be chosen. It accords with this that there is no representation of a *No* in dreams, or at least none which is not ambiguous.

A welcome analogy to this strange behaviour of the dream-work is furnished in the development of language. Many philologists have maintained that in the oldest languages opposites such as: strong—weak, light—dark, large—small, were expressed by the same root word (*antithetical sense of primal words*). Thus, in old Egyptian *ken* stood originally for both "strong" and "weak." In speaking, misunderstanding was guarded against in the use of such ambivalent words by the intonation and accompanying gestures; in writing, by the addition of a so-called "determinative," that is to say, of a picture which was not meant to be expressed orally. Thus, *ken*—"strong" was written in such a way that after the letters there was a picture of a little man standing upright; when *ken* meant "weak," there was added the picture of a man in a slack, crouching attitude. Only at a later period did the two opposite meanings of the same primal word come to be designated in two different ways by slight modifications of the original. Thus, from *ken* meaning "strong—weak" were derived two words: *ken*—"strong" and *kan*—"weak." Nor is it only the oldest languages, in the last stages of their development, which have retained many survivals of these early words capable of meaning either of two opposites, but the same is true of much younger languages, even those which are today still living. I will quote some illustrations of this taken from the work of C. Abel (1884):

In Latin, such ambivalent words are:

*altus*=high or deep. *sacer*=sacred or accursed.

As examples of modifications of the original root, I quote:

*clamare*==to shout. *clam*=quietly, silently, secretly.

*siccus*=dry. *succus*=juice.

and, in German: *Stimme*=voice. *stumm*=dumb.

A comparison of kindred languages yields a large number of examples:

English: lock==to shut. German: *Lock*=hole.

*Lücke*=gap.

English: cleave.<sup>1</sup> German: *kleben*=to stick, adhere.

The English word "without," originally carrying with it both a positive and a negative connotation, is today used in the negative sense only, but it is clear that "with" has the signification, not merely of "adding to," but of "depriving of," from the compounds "withdraw," "withhold" (cf. the German *wieder*).

Yet another peculiarity of the dream-work has its counterpart in the development of language. In ancient Egyptian, as well as in other later languages, the sequence of sounds was transposed so as to result in different words for the same fundamental idea. Examples of this kind of parallels between English and German words may be quoted:

*Topf* (pot)—pot. Boat—tub. Hurry—*Ruhe* (rest).

*Balken* (beam)—*Kloben* (club). wait—*täueren* (to wait).

Parallels between Latin and German:

*capere*—*packen* (to seize). *ren*—*Niere* (kidney).

Such transpositions as have taken place here in the case of single words are made by the dream-work in a variety of ways. The inversion of the meaning, i.e., substitution by the opposite, is a device with which we are already familiar; but, besides this, we find in dreams inversion of situations or of the relations existing between two persons, as though the scene were laid in a "topsy-turvy" world. In dreams often enough the hare chases the hunter. Again, inversion is met with in the sequence of events, so that in dreams cause follows effect, which reminds us of what sometimes happens in a third-rate theatrical performance, when first the hero falls and then the shot which kills him is fired from the wings. Or there are dreams in which the whole arrangement of the elements is inverted, so that in interpreting them the

last must be taken first, and the first last, in order to make sense at all. You remember that we also found this in our study of dream-symbolism, in which the act of plunging or falling into water has the same meaning as that of emerging from water, namely, giving birth or being born and going up steps or a ladder means the same as coming down them. We cannot fail to recognize the advantage reaped for dream-distortion by this freedom from restrictions in representing the dream-thoughts.

These features of the dream-work may be termed *archaic*. They cling to the primitive modes of expression of languages or scripts, and yield the same difficulties, which we shall touch upon later in the course of some critical observations on this topic.

Now let us consider some other aspects of the subject. Clearly what has to be accomplished by the dream-work is the transformation of the latent thoughts, as expressed in words, into perceptual forms, most commonly into visual images. Now our thoughts originated in such perceptual forms; their earliest material and the first stages in their development consisted of sense-impressions, or, more accurately, of memory-pictures of these. It was later that words were attached to these pictures and then connected so as to form thoughts. So that the dream-work subjects our thoughts to a *regressive* process and retraces the steps in their development; in the course of this regression all new acquisitions won during this development of memory-pictures into thoughts must necessarily fall away.

This then is what we mean by the dream-work. Besides what we have learnt of its processes our interest in the manifest dream is bound to recede far into the background; I will, however, devote still a few more remarks to the manifest dream, for, after all, that is the only part of the dream with which we have any direct acquaintance.

It is natural that the manifest dream should lose some of its importance in our eyes. It must strike us as a matter of indifference whether it is carefully composed or split up into a succession of disconnected pictures. Even when the outward form of the dream is apparently full of meaning, we know that this appearance has been arrived at by the process of dream-distortion, and can have as little organic connection with the inner content of the dream as exists between the *façade* of an Italian church and its general structure and ground-plan. At times, however, this *façade* of the dream has a

<sup>1</sup> Both senses of cleave are still alive in English: to cleave (= separate) and to cleave to (= adhere).—TR.

meaning too, reproducing an important part of the latent thoughts with little or no distortion. But we cannot know this until we have interpreted the dream and thus arrived at an opinion with regard to the degree of distortion present. A similar doubt obtains where two elements seem to be closely connected; such connection may contain a valuable hint that the corresponding elements in the latent dream are similarly related, but at other times we can convince ourselves that what is connected in reality has become widely separated in the dream.

In general we must refrain from attempting to explain one part of the manifest dream by another part, as though the dream were a coherent conception and a pragmatic representation. It is in most cases comparable rather to a piece of Breccia stone, composed of fragments of different kinds of stone cemented together in such a way that the markings upon it are not those of the original pieces contained in it. There is, as a matter of fact, one mechanism in the dream-work, known as secondary elaboration, the object of which is to combine the immediate results of the work into a single and fairly coherent whole; during this process the material is often so arranged as to give rise to total misunderstanding, and for this purpose any necessary interpolations are made.

On the other hand, we should not overrate the dream-work or attribute to it more than is its due. Its activity is limited to the achievements here enumerated; condensation, displacement, plastic representation and secondary elaboration of the whole dream; these are all that it can effect. Such manifestations of judgment, criticism, surprise, or deductive reasoning, as are met with in dreams are not brought about by the dream-work and are only very rarely the expression of subsequent reflection about the dream; but are for the most part fragments of the latent thoughts introduced into the manifest dream with more or less modification and in a form suited to the context. Again, the dream-work cannot create conversation in dreams; save in a few exceptional cases, it is imitated from, and made up of, things heard or even said by the dreamer himself on the previous day, which have entered into the latent thoughts as the material or incitement of his dream. Neither do mathematical calculations come into the province of the dream-work; anything of the sort appearing in the manifest dream is generally a mere combination of numbers, a pseudo-calculation, quite

absurd as such, and again only a copy of some calculation comprised in the latent thoughts. In these circumstances it is not surprising that the interest which was felt in the dream-work soon becomes directed instead towards the latent thoughts which disclose themselves in a more or less distorted form through the manifest dream. We are not justified, however, in a theoretical consideration of the subject, in letting our interest stray so far that we altogether substitute the latent thoughts for the dream as a whole, and make some pronouncement on the latter which is only true of the former. It is strange that the findings of psycho-analysis could be so misused as to result in confusion between the two. The term *dream* can only be applied to the *results of the dream-work*, i.e., to the *form* into which the latent thoughts have been rendered by the dream-work.

This work is a process of a quite peculiar type; nothing like it has hitherto been known in mental life. This kind of condensation, displacement, and regressive translation of thoughts into images, is a novelty, the recognition of which in itself richly rewards our efforts in the field of psycho-analysis. You will again perceive, from the parallels to dream-work, the connections revealed between psycho-analytic and other research, especially in the fields of the development of speech and thought. You will only realize the further significance of the insight so acquired when you learn that the mechanism of the dream-work is a kind of model for the formation of neurotic symptoms.

I know, too, that it is not possible for us yet to grasp the full extent of the fresh gain accruing to psychology from these labours. We will only hint at the new proofs thereby afforded of the existence of unconscious mental activities—for this indeed is the nature of the latent dream-thoughts—and at the promise dream-interpretation gives of an approach, wider than we ever guessed at, to the knowledge of the unconscious life of the mind.

Now, however, I think the time has come to give you individual examples of various short dreams, which will illustrate the points for which I have already prepared you.

## TWELFTH LECTURE

### EXAMPLES OF DREAMS AND ANALYSIS OF THEM

YOU must not be disappointed if I present you once more with fragments of dream-interpretations, instead of inviting you to participate in the interpretation of one fine long dream. You

will say that after so much preparation you surely have a right to expect that; and you will express your conviction that, after successful interpretations of so many thousands of dreams, it should long ago have been possible to collect a number of striking examples by which the truth of all our assertions about the dream-work and dream-thoughts could be demonstrated. Yes, but there are too many difficulties in the way of fulfilling this wish of yours.

In the first place, I must confess that there is nobody who makes the interpretation of dreams his main business. In what circumstances then, do we come to interpret them? At times we may occupy ourselves, for no particular purpose, with the dreams of a friend, or we may work out our own dreams over a period of time in order to train ourselves for psycho-analytic work; but chiefly we have to do with the dreams of nervous patients who are undergoing psycho-analytic treatment. These last dreams provide splendid material and are in no respect inferior to those of healthy persons, but the technique of the treatment obliges us to subordinate dream-interpretation to therapeutic purposes and to desist from the attempt to interpret a large number of the dreams as soon as we have extracted from them something of use for the treatment. Again, many dreams which occur during the treatment elude full interpretation altogether; since they have their origin in the whole mass of material in the mind which is as yet unknown to us, it is not possible to understand them until the completion of the cure. To relate such dreams would necessarily involve revealing all the secrets of a neurosis; this will not do for us, since we have taken up the problem of dreams in preparation for the study of the neuroses.

Now I expect you would willingly dispense with this material and would prefer to listen to the explanation of dreams of healthy persons or perhaps of your own. But the content of these dreams makes that impossible. One cannot expose oneself, nor anyone whose confidence has been placed in one, so ruthlessly as a thorough interpretation of a dream would necessitate; for, as you already know, they touch upon all that is most intimate in the personality. Apart from the difficulty arising out of the nature of the material, there is another difficulty as regards relating the dreams. You are aware that the dream seems foreign and strange to the dreamer himself;

how much more so to an outsider to whom his personality is unknown. The literature of psycho-analysis shows no lack of good and detailed dream-analyses; I myself have published some which formed part of the history of certain pathological cases. Perhaps the best example of a dream-interpretation is that published by O. Rank, consisting of the analysis of two mutually related dreams of a young girl. These cover about two pages of print, while the analysis of them runs into 76 pages. It would need almost a whole term's lectures in order to take you through a work of this magnitude. If we selected some fairly long and considerably distorted dream we should have to enter into so many explanations, to adduce so much material in the shape of associations and recollections, and to go down so many sidetracks, that a single lecture would be quite inadequate and would give no clear idea of it as a whole. So I must ask you to be content if I pursue a less difficult course, and relate some fragments from dreams of neurotic patients, in which this or that isolated feature may be recognized. Symbols are the easiest features to demonstrate and, after them, certain peculiarities of the regressive character of dream-representation. I will tell you why I regard each of the following dreams as worth relating.

1. A dream consisting only of two short pictures: *The dreamer's uncle was smoking a cigarette, although it was Saturday. A woman was fondling and caressing the dreamer as though he were her child.*

With reference to the first picture, the dreamer (a Jew) remarked that his uncle was a very pious man who never had done, and never would do, anything so sinful as smoking on the Sabbath. The only association to the woman in the second picture was that of the dreamer's mother. These two pictures or thoughts must obviously be related to one another; but in what way? Since he expressly denied that his uncle would in reality perform the action of the dream, the insertion of the conditional *if* will at once suggest itself. "If my uncle, that deeply religious man, were to smoke a cigarette on the Sabbath, then I myself might be allowed to let my mother fondle me." Clearly, that is as much as to say that being fondled by the mother was something as strictly forbidden as smoking on the Sabbath is to the pious Jew. You will remember my telling you that in the dream-work all relations among the dream-thoughts disappear; the thoughts are broken up into their raw material,

and our task in interpreting is to reinsert these connections which have been omitted.

2. My writings on the subject of dreams have placed me to some extent in the position of public consultant on the question, and for many years now I have received letters from the most diverse quarters communicating dreams to me or asking for my opinion. Naturally I am grateful to all those who have given me sufficient material with their dreams to make an interpretation possible, or have themselves volunteered one. The following dream of a medical student in Munich dating from 1910, belongs to this category; and I quote it because it may prove to you how hard it is, generally speaking, to understand a dream until the dreamer has given us what information he can about it. For I have a suspicion that in the bottom of your hearts you think that the translating of the symbols is the ideal method of interpretation and that you would like to discard that of free association; I want, therefore, to clear your minds of so pernicious an error.

"July 13th, 1910. Towards morning I had the following dream: *I was bicycling down a street in Tübingen, when a brown dachshund came rushing after me and caught hold of one of my heels. I rode a little further and then dismounted, sat down on a step and began to beat the creature off, for it had set its teeth fast in my heel.* (The dog's biting me and the whole scene roused no unpleasant sensations.) *Two elderly ladies were sitting opposite, watching me with grinning faces. Then I woke up and, as has frequently happened before, with the transition to waking consciousness the whole dream was clear to me.*"

In this instance symbolism cannot help us much, but the dreamer goes on to tell us: "I recently fell in love with a girl, just from seeing her in the street; but I had no means of introduction to her. I should have liked best to make her acquaintance through her dachshund, for I am a great animal-lover myself and was attracted by seeing she was one too." He adds that several times he had separated fighting dogs very skilfully, often to the amazement of the onlookers. Now we learn that the girl who had taken his fancy was always seen walking with this particular dog. She, however, has been eliminated from the manifest dream; only the dog associated with her has remained. Possibly the elderly ladies who grinned at him represented her, but the rest of what he tells us does not clear up this point. The fact that he was riding a bicycle in the dream was a direct repe-

tition of the situation as he remembered it, for he had not met the girl with the dog except when he was bicycling.

3. When a man has lost someone dear to him, for a considerable period afterwards he produces a special type of dream, in which the most remarkable compromises are effected between his knowledge that that person is dead and his desire to call him back to life. Sometimes the deceased is dreamt of as being dead, and yet still alive because he does not know that he is dead, as if he would only really die if he did know it; at other times he is half dead and half alive, and each of these conditions has its distinguishing marks. We must not call these dreams merely nonsensical, for to come to life again is no more inadmissible in dreams than in fairy-tales, in which it is quite a common fate. As far as I have been able to analyse such dreams, it appeared that they were capable of a reasonable explanation, but that the pious wish to recall the departed is apt to manifest itself in the strangest ways. I will submit a dream of this sort to you, which certainly sounds strange and absurd enough, and the analysis of which will demonstrate many points already indicated in our theoretical discussions. The dreamer was a man who had lost his father some years previously:

*My father was dead but had been exhumed and looked ill. He went on living, and I did all I could to prevent his noticing it.* Then the dream goes on to other matters, apparently very remote.

That the father was dead we know to be a fact; but the exhumation had not taken place in reality; indeed, the question of real fact has nothing to do with anything that follows. But the dreamer went on to say that after he returned from his father's funeral one of his teeth began to ache. He wanted to treat it according to the Jewish precept: "If thy tooth offend thee, pluck it out," and, accordingly, went to the dentist. The latter, however, said that that was not the way to treat a tooth; one must have patience with it. "I will put something in it," he said, "to kill the nerve, and you must come back in three days' time, when I will take it out again." "This 'taking out,'" said the dreamer suddenly, "is the exhuming."

Now was he right? True, the parallel is not exact, for it was not the tooth which was taken out, but only a dead part of it. As a result of experience, however, we can well credit the dream-work with inaccuracies of this sort. We

must suppose that the dreamer had, by a process of condensation, combined the dead father with the tooth, which was dead and which he yet retained. No wonder then that an absurdity was the result in the manifest dream, for obviously not all that was said about the tooth could apply to the father. What then are we to regard as the *tertium comparationis* between the father and the tooth, what common factor makes the comparison possible?

Such a factor must have existed, for the dreamer went on to observe that he knew the saying that if one dreams of losing a tooth it means that one is about to lose a member of his family.

We know that this popular interpretation is incorrect or at least correct only in a very distorted sense. We shall therefore be the more surprised actually to discover the subject thus touched upon behind the other elements of the dream-content.

Without being pressed further, the dreamer then began to talk of his father's illness and death, and of the relations which had existed between father and son. The illness had been a long one, and the care and treatment of the invalid had cost the son a large sum of money. Yet it never seemed too much to him, nor did his patience ever fail or the wish occur to him that the end should come. He prided himself on his true Jewish filial piety and on his strict observance of the Jewish law. Does not a certain contradiction strike us here in the thoughts relating to the dream? He had identified the tooth with the father. He wanted to treat the former according to the Jewish law which commanded that a tooth which causes pain and annoyance should be plucked out. His father he also wanted to treat according to the precepts of the law, but here the command was that he must pay no heed to expense and annoyance, must take the whole burden upon himself, and not allow any hostile intention to arise against the cause of the trouble. Would not the agreement between the two situations be much more convincing if he had really gradually come to have the same feelings towards his sick father as he had towards his diseased tooth, that is to say, if he had wished for death to put a speedy end to his father's superfluous, painful and costly existence?

I have no doubt that this was, in reality, his attitude towards his father during the protracted illness and that his ostentatious assertions of filial piety were designed to divert his mind from any recollections of the sort. Under

conditions such as these it is no uncommon thing for the death-wish against the father to be roused, and to mask itself with some ostensibly compassionate reflection, such as: "It would be a blessed release for him." But I want you particularly to notice that here in the latent thoughts themselves a barrier has been broken down. The first part of the thoughts was, we may be sure, only temporarily unconscious, that is, during the actual process of the dream-work; the hostile feelings towards the father, on the other hand, had probably been permanently so, possibly dating from childhood and having at times, during the father's illness, crept as it were timidly and in a disguised form into consciousness. We can maintain this with even greater certainty of other latent thoughts which have unmistakably contributed to the content of the dream. There are, it is true, no indications in it of hostile feelings towards the father; but when we enquire into the origin of such hostility in the life of the child we remember that fear of the father arises from the fact that in the earliest years of life it is he who opposes the sexual activity of the boy, as he is usually compelled to do again, after puberty, from motives of social expediency. This was the relation in which our dreamer stood to his father; his affection for him had been tinged with a good deal of respect and dread, the source of which was early sexual intimidation.

We can now explain the further phrases in the dream from the onanism complex. "*He looked ill*" was an allusion to another remark of the dentist's—that it did not look well for a tooth to be missing just there—but it also refers at the same time to the "*looking ill*" by which the young man, during the period of puberty, betrays, or fears lest he might betray, his excessive sexual activity. It was with a lightening of his own heart that in the manifest dream the dreamer transferred the look of illness from himself to his father, an inversion with which you are familiar as a device of the dream-work. "*He went on living*" accords both with the wish to recall the father to life and the promise of the dentist to save the tooth. The phrase "*I did everything I could to prevent his noticing*" is extremely subtly designed to lead us to complete it with the words "that he was dead." The only completion of them that really makes sense, however, is again to be traced to the onanism complex, where it is a matter of course that the young man should do all he can to conceal his sexual life from his father. Finally, I would remind you that the

so-called "tooth-ache dreams" always refer to onanism, and the punishment for it that is feared.

You see how this incomprehensible dream is built up by a piece of remarkable and misleading condensation, by omitting from it all the thoughts that belong to the core of the latent train of thought, and by the creation of ambiguous substitute-formations to represent those thoughts which were deepest and most remote in time.

4. We have already tried repeatedly to get to the bottom of those prosaic and banal dreams which have nothing absurd or strange in them, but which suggest the question: Why should we dream about such trivialities at all? I will therefore quote a fresh example of this sort in the shape of three dreams connected with one another and dreamt by a young lady in the course of a single night.

(a) *She was going through the hall in her house and struck her head on a low-hanging chandelier with such force as to draw blood.* This episode d'd not remind her of anything that had actually happened; her remarks led in quite another direction: "You know how terribly my hair is coming out. Well, yesterday my mother said to me: 'My dear child, if it goes on like this, your head will soon be as bald as your buttocks.'" We see here that the head stands for the other end of the body. No further assistance is required to understand the symbolism of the chandelier: all objects capable of elongation are symbols of the male organ. The real subject of the dream then is a bleeding at the lower end of the body, caused by contact with the penis. This might still have other meanings; the dreamer's further associations show that the dream has to do with the belief that menstruation results from sexual intercourse with a man, a notion about sexual matters which is by no means uncommon amongst immature girls.

(b) *The dreamer saw in a vineyard a deep hole which she knew had been caused by the uprooting of a tree.* Her remark on this point was that "the tree was missing," meaning that she did not see the tree in the dream; but the same phrase serves to express another thought, which leaves us in no doubt as to the symbolic interpretation. The dream refers to another infantile notion on the subject of sex, to the belief that girls originally had the same genital organ as boys and that the later conformation of this organ has been brought about by castration (uprooting the tree).

(c) *The dreamer was standing in front of her writing-table drawer which she knows so well that, if anyone touched it, she would immediately be aware of it.* The writing-table drawer, like all drawers, chests and boxes, is a symbol of the female genital. She knew that when sexual intercourse (or, as she thought, any contact at all) has taken place the genital shows certain indications of the fact, and she had long had a fear of being convicted of this. I think that in all three dreams the main emphasis lies on the idea of *knowing*. She had in mind the time of childish investigations into sexual matters, of the results of which she had been very proud at the time.

5. Here is another example of symbolism. But this time I must preface it with a short account of the mental situation in which the dream occurred. A man and a woman who were in love had spent a night together; he described her nature as maternal, she was one of those women whose desire to have a child comes out irresistibly during caresses. The conditions of their meeting, however, made it necessary to take precautions to prevent the semen from entering the womb. On waking the next morning, the woman related the following dream:

*An officer with a red cap was pursuing her in the street. She fled from him and ran up the staircase, with him after her. Breathless, she reached her rooms and slammed and locked the door behind her. The man remained outside and, peeping through the keyhole in the door, she saw him sitting on a bench outside, weeping.*

In the pursuit by the officer with the red cap and the breathless climbing of the stairs you will recognize the representation of the sexual act. That the dreamer shuts her pursuer out may serve as an example of the device of inversion so frequently employed in dreams, for in reality it was the man who withdrew before the completion of the sexual act. In the same way, she has projected her own feeling of grief on to her partner, for it is he who weeps in the dream, his tears at the same time alluding to the seminal fluid.

You will certainly have heard it said at some time or other that psycho-analysis maintains that all dreams have a sexual meaning. You are now in a position yourselves to form an opinion as to the falseness of this reproach. You have learnt of wish fulfilment dreams, dealing with the gratification of the most obvious needs—hunger, thirst, and the longing for liberty—comfort-dreams, and impatient-dreams, as well as those which are frankly

avaricious and egoistical. You may, however, certainly bear it in mind that, according to the results of psycho-analysis, dreams in which a marked degree of distortion is present *mainly* (but here again not exclusively) give expression to sexual desires.

6. I have a special motive in giving many instances of the use of symbols in dreams. In our first lecture I complained of the difficulty of demonstrating my statements in such a way as to carry conviction with regard to the findings of psycho-analysis, and since then you have doubtless agreed with me. Now the separate propositions of psycho-analysis are nevertheless so intimately related that conviction on a single point easily leads to acceptance of the greater part of the whole theory. It might be said of psycho-analysis that if you give it your little finger it will soon have your whole hand. If you accept the explanation of errors as satisfactory, you cannot logically stop short of belief in all the rest. Now dream-symbolism provides another, equally good, approach to such acceptance. I will recount to you a dream, which has already been published, of a woman of the poorer classes, whose husband was a watchman and of whom we may be sure that she had never heard of dream-symbolism and psycho-analysis. You can then judge for yourselves whether the interpretation arrived at with the help of sexual symbols can justly be called arbitrary or forced.

*"... Then someone broke into the house and in terror she cried for a watchman. But the watchman, accompanied by two tramps, had gone into a church, which had several steps leading up to it. Behind the church there was a mountain and, up above, a thick wood. The watchman wore a helmet, gorget and cloak, and had a full brown beard. The two tramps, who had gone along peaceably with him, had aprons twisted round their hips like sacks. A path led from the church to the mountain and was overgrown on both sides with grass and bushes which grew denser and denser, and at the top of the mountain there was a regular wood."*

You will recognize without any trouble the symbols here employed: the male organ is represented by the trinity of *three* persons appearing, whilst the female sexual organs are symbolized by a landscape with a chapel, a mountain and a wood, and once more you have the act of going up steps as symbolic of the sexual act. The part of the body called in the dream a *mountain* is similarly termed in anatomy the *mons veneris*.

7. I will tell you another dream which is to be explained in the light of symbolism, a dream, moreover, which is noteworthy and convincing from the fact that the dreamer himself translated all the symbols, though he brought no previous theoretical knowledge to the interpretation. This is a very unusual circumstance and we have no accurate idea of the conditions which give rise to it.

*He was walking with his father in a place which must have been the Prater, for they saw the Rotunda with a little building in front of it, to which was made fast a captive balloon which looked rather slack. His father asked him what it was all for; the son wondered at his asking, but explained it nevertheless. Then they came to a court-yard, where a large sheet of metal lay spread out. His father wanted to break off a big piece, but looked round first in case anyone should notice him. He said to his son that all the same he need only tell the overseer and then he could take it straightaway. Some steps led down from this court to a shaft, the sides of which were upholstered with some soft stuff, something like a leather armchair. At the bottom of this shaft was a rather long platform and, beyond it, another shaft.*

The following is the dreamer's own interpretation: "The Rotunda stands for my genitals and the captive balloon in front of it for the penis, which I have had to complain of for being limp." A more detailed translation would then run thus: the rotunda stands for the buttocks (regularly included by children amongst the genitals), the smaller structure in front is the scrotum. In the dream, his father asks him what all this is, i.e., what are the purpose and function of the genitals. To invert this situation so that the son asks the questions is an obvious idea, and, since these questions were never asked in reality, we must construe the dream-thoughts as a wish or take them in a conditional sense: "If I had asked my father to explain . . ." The sequel to this thought we shall find presently.

The court-yard where the sheet-metal lay is not in the first place to be explained symbolically, but is a reference to the father's place of business. From motives of discretion I have substituted *sheet-metal* for the actual material dealt with by him, but otherwise I have made no alteration in the words of the dream. The dreamer had entered his father's business and had been much scandalized by the extremely questionable practices upon which the high

profits largely depended. Hence the sequel to the dream-thought mentioned above would run: "(If I had asked him), he would have deceived me as he deceives his customers." The dreamer himself gives a second explanation for the pulling off the piece of metal which serves to represent commercial dishonesty: it means, he says, the practice of masturbation. Not only is this an explanation with which we have long been familiar, but it is well in accordance with this interpretation that the secret practice of masturbation should be expressed by the opposite idea ("*We may do it openly*"). So the fact that this practice is imputed to the father, as was the questioning in the first scene of the dream, is exactly what we should expect. The dreamer immediately interpreted the shaft, on account of the soft upholstering of the walls, as the vagina, and I, on my own account, offer the remark that going-down as well as going-up stands for sexual intercourse.

The details of the long platform at the bottom of the first shaft, and beyond that the second shaft, were explained by the dreamer himself from his own history. He had practised intercourse for some time and then given it up on account of inhibitions, but hoped to be able to resume it by the help of the treatment.

8. I quote the two following dreams, dreamt by a foreigner with marked polygamous tendencies, because they may serve to illustrate the statement that the dreamer's own person is present in every dream, even when it is disguised in the manifest content. The trunks in the dreams are female symbols.

(a) *The dreamer was going on a journey and his luggage was being taken to the station on a carriage. There were a number of trunks piled one on the top of the other, and amongst them two large black boxes like those of a commercial traveller. He said consolingly to someone: "You see those are only going as far as the station."*

He does, as a matter of fact, travel with a great deal of luggage, and he also brings many stories about women to the treatment. The two black trunks stand for two dark women who at the moment are playing the principal part in his life. One of them wanted to follow him to Vienna, but on my advice he had telegraphed to put her off.

(b) *A scene at a customs house: A fellow-traveller opened his trunk and said nonchalantly, smoking a cigarette: "There is nothing to declare in that." The customs official seemed*

*to believe him, but felt in the trunk again and found a strictly prohibited article. The traveller then said in a resigned way: "Well it can't be helped."* The dreamer himself is the traveller and I am the official. He is generally very straightforward with me, but had made up his mind to conceal from me a relation which he had recently formed with a lady, for he assumed quite correctly, that I knew her. He dis-places on to a stranger the embarrassing situation of being detected, so that he himself does not seem to come into the dream at all.

9. Here we have an example of a symbol which I have not yet mentioned:

*The dreamer met his sister with two friends who were themselves sisters. He shook hands with these two, but not with his sister.*

There was no real episode connected with this in his mind. Instead, his thoughts went back to a time when his observations led him to wonder why a girl's breasts are so late in developing. The two sisters, therefore, stand for the breasts; he would have liked to grasp them with his hand, if only it had not been his sister.

10. Here is an example of death symbolism in dreams: *The dreamer was crossing a very high, steep, iron bridge, with two people whose names he knew but forgot on waking. Suddenly both of them had vanished and he saw a ghostly man in a cap and an overall. He asked him whether he were the telegraph messenger . . . "No." Or the coachman? . . . "No." He then went on, and in the dream, had a feeling of great dread; on waking, he followed it up with the phantasy that the iron bridge suddenly broke and that he fell into the abyss.*

When stress is laid upon the fact that people in a dream are unknown to the dreamer, or that he has forgotten their names, they are, as a rule, persons with whom he is intimately connected. The dreamer was one of a family of three children; if he had ever wished for the death of the other two, it would be only just that he should be visited with the fear of death. With reference to the telegraph messenger, he remarked that they always bring bad news. From his uniform, the man in the dream might have been a lamplighter, who also puts out the lights, as the spirit of death extinguishes the torch of life. With the coachman he associated Uhland's poem of the voyage of King Karl, and recalled a dangerous sail on a lake with two companions, when he played the part of the king in the poem. The iron bridge suggested

to him a recent accident, also the stupid saying: "Life is a suspension bridge."

11. The following may be regarded as another example of a death dream:

*An unknown gentleman was leaving a black-edged visiting card on the dreamer.*

12. I give another dream which will interest you from several points of view; it is to be traced partly, however, to a neurotic condition in the dreamer:

*He was in a train which stopped in the open country. He thought there was going to be an accident and that he must make his escape, so he went through all the compartments, killing everyone he met—driver, guard, and so on.*

This dream recalls a story told him by a friend. On a certain Italian line, an insane man was being conveyed in a small compartment, but by some mistake a passenger was allowed to get in with him. The madman murdered the other traveller. Thus, the dreamer identified himself with this insane man, his reason being that he was at times tormented by an obsession that he must make away with "everyone who shared his knowledge." Then he himself found a better motivation for the dream. The day before, he had seen at the theatre a girl he had meant to marry but had given up because she gave him cause for jealousy. Knowing the intensity which jealousy could assume in him, he would really have been mad to want to marry her. That is to say, he thought her so unreliable that his jealousy would have led him to murder everyone who got in his way. The going through a number of rooms, or, as here, compartments, we have already learnt to know as a symbol of marriage (the expression of monogamy according to the rule of opposites).

With reference to the train's stopping in the open country and the fear of an accident, he told the following story:

Once when such a sudden halt occurred on the line outside a station, a young lady who was in the carriage said that perhaps there was going to be a collision, and that the best thing to do was to raise the legs high. This phrase "raise the legs" had associations with many walks and excursions into the country, which he had shared with the girl mentioned above in the happy early days of their love. Here was a new argument for the contention that he would be mad to marry her now; nevertheless, my knowledge of the situation led me to regard it as certain that there existed in him all the

same the desire to fall a victim to this form of madness.

### THIRTEENTH LECTURE

#### ARCHAIC AND INFANTILE FEATURES IN DREAMS

LET us start afresh from our conclusion that, under the influence of the censorship, the dream-work translates the latent dream-thoughts into another form. These thoughts are of the same nature as the familiar, conscious thoughts of waking life; the new form in which they are expressed is, owing to many peculiar characteristics, incomprehensible to us. We have said that it goes back to phases in our intellectual development which we have long outgrown—to hieroglyphic writing, to symbolic-connections, possibly to conditions which existed before the language of thought was evolved. On this account we called the form of expression employed by the dream-work *archaic* or *regressive*.

From this you may draw the inference that a more profound study of the dream-work must lead to valuable conclusions about the initial stages of our intellectual development, of which at present little is known. I hope it will be so, but so far this task has not been attempted. The era to which the dream-work takes us back is *primitive* in a two-fold sense: in the first place, it means the early days of the *individual*—his childhood—and, secondly, in so far as each individual repeats in some abbreviated fashion during childhood the whole course of the development of the human race, the reference is *phylogenetic*. I believe it not impossible that we may be able to discriminate between that part of the latent mental processes which belongs to the early days of the individual and that which has its roots in the infancy of the race. It seems to me, for instance, that symbolism, a mode of expression which has never been individually acquired, may claim to be regarded as a racial heritage.

This, however, is not the only archaic feature in dreams. You are all familiar from actual experience with the peculiar *amnesia of childhood* to which we are subject. I mean that the first years of life, up to the age of five, six, or eight, have not left the same traces in memory as our later experiences. True, we come across individuals who can boast of continuous recollection from early infancy to the present time, but it is incomparably more common for the opposite, a blank in memory, to be found. In my opinion, this has not aroused suf-

ficient surprise. At two years old the child can speak well and soon shows his capacity for adapting himself to complicated mental situations, and, moreover, says things which he himself has forgotten when they are repeated to him years later. And yet memory is more efficient in early years, being less overburdened than it is later. Again, there is no reason to regard the function of memory as an especially high or difficult form of mental activity; on the contrary, excellent memory may be found in people who are yet on a very low plane intellectually.

But I must draw your attention to a second peculiarity based upon the first—namely, that from the oblivion in which the first years of childhood are shrouded certain clearly retained recollections emerge, mostly in the form of plastic images, for the retention of which there seems no adequate ground. Memory deals with the mass of impressions received in later life by a process of selection, retaining what is important and omitting what is not; but with the recollections retained from childhood this is not so. They do not necessarily reflect important experiences in childhood, not even such as must have seemed important from the child's standpoint, but are often so banal and meaningless in themselves that we can only ask ourselves in amazement why just this particular detail has escaped oblivion. I have tried, with the help of analysis, to attack the problem of childhood amnesia and of the fragments of recollection which break through it, and have come to the conclusion that, whatever may appear to the contrary, the child no less than the adult only retains in memory what is important; but that what is important is represented (by the processes of condensation and, more especially of displacement, already familiar to you) in the memory by something apparently trivial. For this reason I have called these childhood recollections *screen-memories*; a thorough analysis can evolve from them all that has been forgotten.

It is a regular task in psycho-analytic treatment to fill in the blank in infantile memories, and, in so far as the treatment is successful to any extent at all (very frequently, therefore) we are enabled to bring to light the content of those early years long buried in oblivion. These impressions have never really been forgotten, but were only inaccessible and latent, having become part of the unconscious. But sometimes it happens that they emerge spontane-

ously from the unconscious, and it is in connection with dreams that this happens. It is clear that the dream-life knows the way back to these latent, infantile experiences. Many good illustrations of this are to be found in psychoanalytical literature, and I myself have been able to furnish a contribution of the sort. I once dreamt in a particular connection of someone who had evidently done me a service and whom I saw plainly. He was a one-eyed man, short, fat and high-shouldered; from the context I gathered that he was a doctor. Fortunately I was able to ask my mother, who was still living, what was the personal appearance of the doctor who attended us at the place where I was born and which I left at the age of three; she told me that he had only one eye and was short, fat and high-shouldered; I learnt also of the accident which was the occasion of this doctor's being called in and which I had forgotten. This command of the forgotten material of the earliest years of childhood is thus a further *archaic* feature of dreams.

This knowledge has a bearing on another of the problems which up to the present have proved insoluble. You will remember the astonishment caused by our discovery that dreams have their origin in actively evil or in excessive sexual desires, which have made both the dream-censorship and dream-distortion necessary. Supposing now that we have interpreted a dream of this sort, and the circumstances are specially favourable in that the dreamer does not quarrel with the interpretation itself, he does nevertheless invariably ask how any such wish could come into his mind, since it seems quite foreign to him and he is conscious of desiring the exact opposite. We need have no hesitation in pointing out to him the origin of the wish he repudiates: these evil impulses may be traced to the past, often indeed to a past which is not so very far away. It may be demonstrated that he once knew and was conscious of them, even if this is no longer so. A woman who had a dream meaning that she wished to see her only daughter (then seventeen years old) lying dead found, with our help, that at one time she actually had cherished this death-wish. The child was the offspring of an unhappy marriage, which ended in the speedy separation of husband and wife. Once when the child was as yet unborn the mother, in an access of rage after a violent scene with her husband, beat her body with her clenched fists

in order to kill the baby in her womb. How many mothers who today love their children tenderly, perhaps with excessive tenderness, yet conceived them unwillingly and wished that the life within them might not develop further; and have indeed turned this wish into various actions, fortunately of a harmless kind. The later death-wish against beloved persons, which appears so puzzling, thus dates from the early days of the relationship to them.

A father, whose dream when interpreted shows that he wished for the death of his eldest and favourite child, is in the same way obliged to recall that there was a time when this wish was not unknown to him. The man, whose marriage had proved a disappointment, often thought when the child was still an infant that if the little creature who meant nothing to him were to die he would again be free and would make better use of his freedom. A large number of similar impulses of hate are to be traced to a similar source; they are recollections of something belonging to the past, something which was once in consciousness and played its part in mental life. From this you will be inclined to draw the conclusion that such dreams and such wishes would not occur in cases where there have been no changes of this sort in the relations between two persons, that is to say, where the relation has been of the same character from the beginning. I am prepared to grant you this conclusion, only I must warn you that you have to consider, not the literal meaning of the dream, but what it signifies on interpretation. It may be that the manifest dream of the death of some beloved person was only using this as a terrible mask, whilst really meaning something totally different, or it is possible that the beloved person is an illusory substitute for someone else.

This situation will, however, raise in you another and much more serious question. You will say: "Even though this death-wish did at one time actually exist and this is confirmed by recollection, that is still no true explanation; for the desire has long since been overcome and surely at the present time can exist in the unconscious merely as a recollection, of no affective value, and not as a powerful exciting agent. For this later assumption we have no evidence. Why is the wish recollected at all in dreams?" This is a question which you are really justified in asking; the attempt to answer it would take us far afield and would oblige us to define our position with regard to

one of the most important points in the theory of dreams. But I must keep within the limits of our discussion and must forbear to follow up this question; so you must be reconciled to leaving it for the present. Let us content ourselves with the actual evidence that this wish, long since subdued, can be proved to have given rise to the dream, and let us continue our enquiry whether other evil wishes also can be traced in the same way to the past.

Let us keep to the death-wishes, which we shall certainly find mostly derived from the unbounded egoism of the dreamer. Wishes of this sort are very often found to be the underlying agents of dreams. Whenever anyone gets in our way in life—and how often must this happen when our relations to one another are so complicated!—a dream is immediately prepared to make away with that person, even if it be father, mother, brother or sister, husband or wife. It appeared to us amazing that such wickedness should be innate in humanity, and certainly we were not inclined to admit without further evidence that this result of our interpretation of dreams was correct. But, when once we had seen that the origin of wishes of this sort must be looked for in the past, we had little difficulty in finding the period in the past of the individual in which there is nothing strange in such egoism and such wishes, even when directed against the nearest and dearest. A child in his earliest years (which later are veiled in oblivion) is just the person who frequently displays such egoism in boldest relief; invariably, unmistakable tendencies of this kind, or, more accurately, surviving traces of them, are plainly visible in him. For a child loves himself first and only later learns to love others and to sacrifice something of his own ego to them. Even the people whom he seems to love from the outset are loved in the first instance because he needs them and cannot do without them—again therefore, from motives of egoism. Only later does the impulse of love detach itself from egoism: it is a literal fact that the child learns how to love through his own egoism.

In this connection it will be instructive to compare a child's attitude towards his brothers and sisters with his attitude towards his parents. The little child does not necessarily love his brothers and sisters, and often he is quite frank about it. It is unquestionable that in them he sees and hates his rivals, and it is well known how commonly this attitude persists

without interruption for many years, till the child reaches maturity and even later. Of course it often gives place to a more tender feeling, or perhaps we should say it is overlaid by this, but the hostile attitude seems very generally to be the earlier. We can most easily observe it in children of two and a half to four years old when a new baby arrives, which generally meets with a very unfriendly reception; remarks such as "I don't like it. The stork is to take it away again" are very common. Subsequently every opportunity is seized to disparage the new-comer; attempts are even made to injure it and actual attacks upon it are by no means unheard-of. If the difference in age is less, by the time the child's mental activity is more fully developed the rival is already in existence and he adapts himself to the situation; if on the other hand there is a greater difference between their ages, the new baby may rouse certain kindly feelings from the first, as an object of interest, a sort of living doll; and when there is as much as eight years or more between them, especially if the elder child is a girl, protective, motherly impulses may at once come into play. But, speaking honestly, when we find a wish for the death of a brother or a sister latent in a dream we need seldom be puzzled, for we find its origin in early childhood without much trouble, or indeed, quite often in the later years when they still lived together.

There is probably no nursery without violent conflicts between the inhabitants, actuated by rivalry for the love of the parents, competition for possessions shared by them all, even for the actual space in the room they occupy. Such hostility is directed against older as well as younger brothers and sisters. I think it was Bernard Shaw who said: "If there is anyone whom a young English lady hates more than her mother it is her elder sister." Now there is something in this dictum which jars upon us; it is hard enough to bring ourselves to understand hatred and rivalry between brothers and sisters, but how can feelings of hate force themselves into the relation between mother and daughter, parents and children?

This relationship is no doubt a more favourable one, also from the children's point of view; and this too is what our expectations require: we find it far more offensive for love to be lacking between parents and children than between brothers and sisters. We have, so to speak, sanctified the former love while allow-

ing the latter to remain profane. Yet everyday observation may show us how frequently the sentiments entertained towards each other by parents and grown-up children fall short of the ideal set up by society, and how much hostility lies smouldering, ready to burst into flame if it were not stifled by considerations of filial or parental duty and by other, tender impulses. The motives for this hostility are well known, and we recognize a tendency for those of the same sex to become alienated, daughter from mother and father from son. The daughter sees in her mother the authority which imposes limits to her will, whose task it is to bring her to that renunciation of sexual freedom which society demands; in certain cases, too, the mother is still a rival, who objects to being set aside. The same thing is repeated still more blatantly between father and son. To the son the father is the embodiment of the social compulsion to which he so unwillingly submits, the person who stands in the way of his following his own will, of his early sexual pleasures and, when there is family property, of his enjoyment of it. When a throne is involved, this impatience for the death of the father may approach tragic intensity. The relation between father and daughter or mother and son would seem less liable to disaster; the latter relation furnishes the purest examples of unchanging tenderness, undisturbed by any egoistic consideration.

Why, you ask, do I speak of things so banal and so well-known to everybody? Because there exists an unmistakable tendency in people's minds to deny the significance of these things in real life and to pretend that the social ideal is much more frequently realized than it actually is. But it is better that psychology should tell the truth than that it should be left to cynics to do so. This general denial is only applied to real life, it is true; for fiction and drama are free to make use of the motives laid bare when these ideals are rudely disturbed.

There is nothing to wonder at therefore if the dreams of a great number of people bring to light the wish for the removal of their parents, especially of the parent whose sex is the same as the dreamer's. We may assume that the wish exists in waking life as well, sometimes even in consciousness if it can disguise itself behind another motive, as the dreamer in our third example disguised his real thought by pity for his father's useless suffering. It is but rarely that hostility reigns alone—far more

often it yields to more tender feelings which finally suppress it, when it has to wait in abeyance till a dream shows it, as it were, in isolation. That which the dream shows in a form magnified by this very isolation resumes its true proportions when our interpretation has assigned to it its proper place in relation to the rest of the dreamer's life. (H. Sachs.) But we also find this death-wish where there is no basis for it in real life and where the adult would never have to confess to entertaining it in his waking life. The reason for this is that the deepest and most common motive for estrangement, especially between parent and child of the same sex, came into play in the earliest years of childhood. I refer to that rivalry of affections in which sexual elements are plainly emphasized. The son, when quite a little child, already begins to develop a peculiar tenderness towards his mother, whom he looks upon as his own property, regarding his father in the light of a rival who disputes this sole possession of his; similarly the little daughter sees in her mother someone who disturbs her tender relation to her father and occupies a place which she feels she herself could very well fill. Observation shows us how far back these sentiments date, sentiments which we describe by the term *Oedipus complex*, because in the Oedipus myth the two extreme forms of the wishes arising from the situation of the son—the wish to kill the father and to marry the mother—are realized in an only slightly modified form. I do not assert that the Oedipus complex exhausts all the possible relations which may exist between parents and children; these relations may well be a great deal more complicated. Again, this complex may be more or less strongly developed, or it may even become inverted, but it is a regular and very important factor in the mental life of the child; we are more in danger of underestimating than of overestimating its influence and that of the developments which may follow from it. Moreover, the parents themselves frequently stimulate the children to react with an Oedipus complex, for parents are often guided in their preferences by the difference in sex of their children, so that the father favours the daughter and the mother the son; or else, where conjugal love has grown cold, the child may be taken as a substitute for the love-object which has ceased to attract.

It cannot be said that the world has shown great gratitude to psycho-analytic research for the discovery of the Oedipus complex; on the

contrary, the idea has excited the most violent opposition in grown-up people; and those who omitted to join in denying the existence of sentiments so universally reprehended and tabooed have later made up for this by proffering interpretations so wide of the mark as to rob the complex of its value. My own unchanged conviction is that there is nothing in it to deny or to gloss over. We ought to reconcile ourselves to facts in which the Greek myth itself saw the hand of inexorable destiny. Again, it is interesting to find that the Oedipus complex, repudiated in actual life and relegated to fiction, has there come to its own. O. Rank in a careful study of this theme has shown how this very complex has supplied dramatic poetry with an abundance of motives in countless variations, modifications and disguises, in short, subject to just the distortion familiar to us in the work of the dream-censorship. So we may look for the Oedipus complex even in those dreamers who have been fortunate enough to escape conflicts with their parents in later life; and closely connected with this we shall find what is termed the *castration complex*, the reaction to that intimidation in the field of sex or to that restraint of early infantile sexual activity which is ascribed to the father.

What we have already ascertained has guided us to the study of the child's mental life, and we may now hope to find in a similar way an explanation of the source of the other kind of prohibited wishes in dreams, i.e., the excessive sexual desires. We are impelled therefore to study the development of the sexual life of the child, and here from various sources we learn the following facts. In the first place, it is an untenable fallacy to suppose that the child has no sexual life and to assume that sexuality first makes its appearance at puberty, when the genital organs come to maturity. On the contrary he has from the very beginning a sexual life rich in content, though it differs in many points from that which later is regarded as normal. What in adult life are termed *perversions* depart from the normal in the following respects: (1) in a disregard for the barriers of species (the gulf between man and beast), (2) in the insensibility to barriers imposed by disgust, (3) in the transgression of the incest-barrier (the prohibition against seeking sexual gratification with close blood-relations), (4) in homosexuality and, (5) in the transferring of the part played by the genital organs to other organs and different areas of the body. All

these barriers are not in existence from the outset, but are only gradually built up in the course of development and education. The little child is free from them: he does not perceive any immense gulf between man and beast, the arrogance with which man separates himself from the other animals only dawns in him at a later period. He shows at the beginning of life no disgust for excrement, but only learns this feeling slowly under the influence of education; he attaches no particular importance to the difference between the sexes, in fact he thinks that both have the same formation of the genital organs; he directs his earliest sexual desires and his curiosity to those nearest to him or to those who for other reasons are specially beloved—his parents, brothers and sisters or nurses; and finally we see in him a characteristic which manifests itself again later at the height of some love-relationship—namely, he does not look for gratification in the sexual organs only, but discovers that many other parts of the body possess the same sort of sensibility and can yield analogous pleasurable sensations, playing thereby the part of genital organs. The child may be said then to be *polymorphously perverse*, and even if mere traces of all these impulses are found in him, this is due on the one hand to their lesser intensity as compared with that which they assume in later life and, on the other hand, to the fact that education immediately and energetically suppresses all sexual manifestations in the child. This suppression may be said to be embodied in a theory; for grown-up people endeavour to overlook some of these manifestations, and, by misinterpretation, to rob others of their sexual nature, until in the end the whole thing can be altogether denied. It is often the same people who first inveigh against the sexual *naughtiness* of children in the nursery and then sit down to their writing-tables to defend the sexual purity of the same children. When they are left to themselves or when they are seduced, children often display perverse sexual activity to a really remarkable extent. Of course grown-up people are right in not taking this too seriously and in regarding it, as they say, as *childish tricks and play*, for the child cannot be judged either by a moral or legal code as if he were mature and fully responsible; nevertheless these things do exist, and they have their significance both as evidence of innate constitutional tendencies and inasmuch as they cause and foster later devel-

opments: they give us an insight into the child's sexual life and so into that of humanity as a whole. If, then, we find all these perverse wishes behind the distortions of our dreams, it only means that dreams in *this respect also* have regressed completely to the infantile condition.

Amongst these forbidden wishes special prominence must still be given to the incestuous desires, i.e., those directed towards sexual intercourse with parents or brothers and sisters. You know in what abhorrence human society holds, or at least professes to hold, such intercourse, and what emphasis is laid upon the prohibitions of it. The most preposterous attempts have been made to account for this horror of incest: some people have assumed that it is a provision of nature for the preservation of the species, manifesting itself in the mind by these prohibitions because inbreeding would result in racial degeneration; others have asserted that propinquity from early childhood has deflected sexual desire from the persons concerned. In both these cases, however, the avoidance of incest would have been automatically secured and we should be at a loss to understand the necessity for stern prohibitions, which would seem rather to point to a strong desire. Psycho-analytic investigations have shown beyond the possibility of doubt that an *incestuous love-choice* is in fact the first and the regular one, and that it is only later that any opposition is manifested towards it, the causes of which are not to be sought in the psychology of the individual.

Let us sum up the results which our excursions into child-psychology have brought to the understanding of dreams. We have learnt not only that the material of the forgotten childish experiences is accessible to the dream, but also that the child's mental life, with all its peculiarities, its egoism, its incestuous object-choice, persists in it and therefore in the unconscious, and that our dreams take us back every night to this infantile stage. This corroborates the belief that *the Unconscious is the infantile mental life*, and, with this, the objectionable impression that so much evil lurks in human nature grows somewhat less. For this terrible evil is simply what is original, primitive and infantile in mental life, what we find in operation in the child, but in part overlook in him because it is on so small a scale, and in part do not take greatly to heart because we do not demand a high ethical standard in a child. By regressing to this infantile stage our dreams

appear to have brought the evil in us to light, but the appearance is deceptive, though we have let ourselves be dismayed by it; we are not so evil as the interpretation of our dreams would lead us to suppose.

If the evil impulses of our dreams are merely infantile, a reversion to the beginnings of our ethical development, the dream simply making us children again in thought and feeling, it is surely not reasonable to be ashamed of these evil dreams. But the reasoning faculty is only part of our mental life; there is much in it besides which is not reasonable, and so it happens that, although it is unreasonable, we nevertheless are ashamed of such dreams. We subject them to the dream-censorship and are ashamed and indignant when one of these wishes by way of exception penetrates our consciousness in a form so undisguised that we cannot fail to recognize it; yes, we even at times feel just as much ashamed of a distorted dream as if we really understood it. Just think of the outraged comment of the respectable elderly lady upon her dream about *love service*, although it was not interpreted to her. So the problem is not yet solved, and it is still possible that if we pursue this question of the evil in dreams we may arrive at another conclusion and another estimate of human nature.

Our whole enquiry has led to two results which, however, merely indicate the beginning of new problems and new doubts. In the first place: the regression in dreams is one not only of form but of substance. Not only does it translate our thoughts into a primitive form of expression, but it also re-awakens the peculiarities of our primitive mental life—the old supremacy of the ego, the initial impulses of our sexual life, even restores to us our old intellectual possession if we may conceive of symbolism in this way. And secondly: all these old infantile characteristics, which were once dominant and solely dominant, must today be accounted to the unconscious and must alter and extend our views about it. *Unconscious* is no longer a term for what is temporarily latent: the unconscious is a special realm, with its own desires and modes of expression and peculiar mental mechanisms not elsewhere operative. Yet the latent dream-thoughts disclosed by our interpretation do not belong to this realm; rather they correspond to the kind of thoughts we have in waking life also. And yet they are unconscious: how is the paradox to be resolved? We begin to realize that here we must discriminate. Something which has its origin in our

conscious life and shares its characteristics—we call it the *residue* from the previous day—meets together with something from the realm of the unconscious in the formation of a dream, and it is between these two regions that the dream-work is accomplished. The influence of the unconscious impinging upon this residue probably constitutes the condition for regression. This is the deepest insight into the nature of dreams possible to us until we have explored further fields in the mind; but soon it will be time to give another name to the unconscious character of the latent dream-thoughts, in order to distinguish it from that unconscious material which has its origin in the province of the infantile.

We can of course also ask: What is it that forces our mental activity during sleep to such regression? Why cannot the mental stimuli that disturb sleep be dealt with without it? And if on account of the dream-censorship the mental activity has to disguise itself in the old, and now incomprehensible, form of expression, what is the object of re-animating the old impulses, desires and characteristics, now surmounted; what, in short, is the use of *regression in substance* as well as in *form*? The only satisfactory answer would be that this is the one possible way in which dreams can be formed, that, dynamically considered, the relief from the stimulus giving rise to the dream cannot otherwise be accomplished. But this is an answer for which, at present, we have no justification.

## FOURTEENTH LECTURE

### WISH-FULFILMENT

SHALL I remind you once more of the steps by which we have arrived at our present position? When in applying our technique we came upon the distortion in dreams, we made up our minds to avoid it for the moment and turned to the study of infantile dreams for some definite information about the nature of dreams in general. Next, equipped with the results of this investigation, we attacked the question of dream-distortion directly, and I hope that bit by bit we have also mastered that. Now, however, we are bound to admit that our findings in these two directions do not exactly tally, and it behooves us to combine and correlate our results.

Both enquiries have made it plain that the essential feature in the dream-work is the transformation of thoughts into hallucinatory experi-

ence. It is puzzling enough to see how this process is accomplished, but this is a problem for general psychology, and we have not to deal with it here. We have learnt from children's dreams that the object of the dream-work is to remove, by means of the fulfilment of some wish, a mental stimulus which is disturbing sleep. We could make no similar pronouncement with regard to distorted dreams until we understood how to interpret them, but from the outset we expected to be able to bring our ideas about them into line with our views on infantile dreams. This expectation was for the first time fulfilled when we recognized that all dreams are really children's dreams; that they make use of infantile material and are characterized by impulses and mechanisms which belong to the childish mind. When we feel we have mastered the distortion in dreams we must go on to find out whether the notion that dreams are WISH-FULFILMENTS holds good of distorted dreams also.

We have just subjected a series of dreams to interpretation, but without taking the question of wish-fulfilment into consideration at all. I feel certain that, while we were talking about them, the question repeatedly forced itself upon you: "What has become of the wish-fulfilment which is supposed to be the object of the dream-work?" Now this question is important, for it is the one which our lay critics are constantly asking. As you know, mankind has an instinctive antipathy to intellectual novelties; one of the ways in which this shows itself is that any such novelty is immediately reduced to its very smallest compass, and if possible embodied in some catch-word. *Wish-fulfilment* has become the catch-word for the new theory of dreams. Directly they hear that dreams are said to be wish-fulfilments, the laity asks: "Where does the wish-fulfilment come in?" and their asking the question amounts to a repudiation of the idea. They can immediately think of countless dreams of their own which were accompanied by feeling so unpleasant as sometimes to reach the point of agonizing dread; and so this statement of the psycho-analytical theory of dreams appears to them highly improbable. It is easy to reply that in distorted dreams the wish-fulfilment is not openly expressed, but has to be looked for, so that it cannot be shown until the dreams have been interpreted. We know too that the wishes underlying these distorted dreams are those which are prohibited and rejected by the censorship, and that it is just their existence which is the

cause of distortion and the motive for the intervention of the censorship. But it is difficult to make the lay critic understand that we must not ask about the wish-fulfilment in a dream before it has been interpreted; he always forgets this. His reluctance to accept the theory of wish-fulfilment is really nothing but the effect of the dream-censorship, causing him to replace the real thought by a substitute, and following from his repudiation of these censored dream-wishes.

Of course we ourselves must feel the need to explain why so many dreams are painful in content; and in particular we shall want to know how we come to have *anxiety-dreams*. Here for the first time we are confronted with the problem of the affects in dreams; a problem which deserves special study, but one which we cannot concern ourselves with just now, unfortunately. If the dream is a wish-fulfilment, it should be impossible for any painful emotions to come into it: on this point the lay critics seem to be right. But the matter is complicated by three considerations which they have overlooked.

First, it may happen that the dream-work is not wholly successful in creating a wish-fulfilment, so that part of the painful feeling in the latent thoughts is carried over into the manifest dream. Analysis would then have to show that these thoughts were a great deal more painful than the dream which is formed from them; this much can be proved in every instance. We admit then that the dream-work has failed in its purpose, just as a dream of drinking excited by the stimulus of thirst fails to quench that thirst. One is still thirsty after it and has to wake up and drink. Nevertheless, it is a proper dream: it has renounced nothing of its essential nature. We must say: "*Ut desint vires, tamen est laudanda voluntas*."<sup>1</sup> The clearly recognizable intention remains a praiseworthy one, at any rate. Such instances of failure in the work are by no means rare, and one reason is that it is so much more difficult for the dream-work to produce the required change in the nature of the affect than to modify the content; affects are often very intractable. So it happens that in the process of the dream-work the painful *content* of the dream-thoughts is transformed into a wish-fulfilment while the painful *affect* persists unchanged. When this occurs, the affect is quite out of harmony with the content, which gives our critics the oppor-

<sup>1</sup> The will is commendable, though the ability may be wanting.

tunity of remarking that the dream is so far from being a wish-fulfilment that even a harmless content may be accompanied in it by painful feelings. Our answer to this rather unintelligent comment will be that it is just in dreams of this sort that the wish-fulfilling tendency of the dream-work is most apparent, because it is there seen in isolation. The mistake in this criticism arises because people who are not familiar with the neuroses imagine a more intimate connection between content and affect than actually exists, and so cannot understand that there may be an alteration in the content while the accompanying affect remains unchanged.

A second consideration, much more important and far-reaching but equally overlooked by the laity, is the following. A wish fulfilment must certainly bring some pleasure; but we go on to ask: "To whom?" Of course, to the person who has the wish. But we know that the attitude of the dreamer towards his wishes is a peculiar one: he rejects them, censors them, in short, he will have none of them. Their fulfilment then can afford him no pleasure, rather the opposite, and here experience shows that this *opposite*, which has still to be explained, takes the form of *anxiety*. The dreamer, where his wishes are concerned, is like two separate people closely linked together by some important thing in common. Instead of enlarging upon this I will remind you of a well-known fairy-tale in which you will see these relationships repeated. A good fairy promised a poor man and his wife to fulfil their first three wishes. They were delighted and made up their minds to choose the wishes carefully. But the woman was tempted by the smell of some sausages being cooked in the next cottage and wished for two like them. Lo! and behold, there they were—and the first wish was fulfilled. With that, the man lost his temper and in his resentment wished that the sausages might hang on the tip of his wife's nose. This also came to pass, and the sausages could not be removed from their position; so the second wish was fulfilled, but it was the man's wish and its fulfilment was most unpleasant for the woman. You know the rest of the story: as they were after all man and wife, the third wish had to be that the sausages should come off the end of the woman's nose. We might make use of this fairy-tale many times over in other contexts, but here it need only serve to illustrate the fact that it is possible for the fulfilment of one person's wish to be very disagreeable to

someone else, unless the two people are entirely at one.

It will not be difficult now to arrive at a still better understanding of anxiety-dreams. There is just one more observation to be made use of and then we may adopt an hypothesis which is supported by several considerations. The observation is that anxiety-dreams often have a content in which there is no distortion; it has, so to speak, escaped the censorship. This type of dream is frequently an undisguised wish-fulfilment, the wish being of course not one which the dreamer would accept but one which he has rejected; anxiety has developed in place of the working of the censorship. Whereas the infantile dream is an open fulfilment of a wish admitted by the dreamer, and the ordinary distorted dream is the disguised fulfilment of a repressed wish, the formula for the anxiety-dream is that it is the open fulfilment of a repressed wish. Anxiety is an indication that the repressed wish has proved too strong for the censorship and has accomplished or was about to accomplish its fulfilment in spite of it. We can understand that fulfilment of a repressed wish can only be, for us who are on the side of the censorship, an occasion for painful emotions and for setting up a defence. The anxiety then manifested in our dreams is, if you like to put it so, anxiety experienced because of the strength of wishes which at other times we manage to stifle. The study of dreams alone does not reveal to us why this defence takes the form of anxiety; obviously we must consider the latter in other connections.

The hypothesis which holds good for anxiety-dreams without any distortion may be adopted also for those which have undergone some degree of distortion, and for other kinds of unpleasant dreams in which the accompanying unpleasant feelings probably approximate to anxiety. Anxiety-dreams generally wake us; we usually break off our sleep before the repressed wish behind the dream overcomes the censorship and reaches complete fulfilment. In such a case the dream has failed to achieve its purpose, but its essential character is not thereby altered. We have compared the dream with a night-watchman, a guardian of sleep, whose purpose it is to protect sleep from interruption. Now night-watchmen also, just like dreams, have to rouse sleepers when they are not strong enough to ward off the cause of disturbance or danger alone. Nevertheless we do sometimes succeed in continuing to sleep even when our dreams begin to give us some uneasiness and

to turn to anxiety. We say to ourselves in sleep: "It is only a dream after all," and go on sleeping.

You may ask *when* it happens that the dream-wish is able to overcome the censorship. This may depend either on the wish or on the censorship: it may be that for unknown reasons the strength of the wish at times becomes excessive; but our impression is that it is more often the attitude of the censorship which is responsible for this shifting in the balance of power. We have already heard that the censorship works with varying intensity in each individual instance, treating the different elements with different degrees of strictness; now we may add that it is very variable in its general behaviour and does not show itself always equally severe towards the same element. If then it chanced that the censorship feels itself for once powerless against some dream-wish which threatens to overflow it, it then, instead of making use of distortion, employs the last weapon left to it and destroys sleep by bringing about an access of anxiety.

At this point it strikes us that we still have no idea why these evil, rejected wishes rise up just at night-time, so as to disturb us when we sleep. The answer can hardly be found except in another hypothesis which goes back to the nature of sleep itself. During the day the heavy pressure of a censorship is exercised upon these wishes and, as a rule, it is impossible for them to make themselves felt at all. But in the night it is probable that this censorship, like all the other interests of mental life, is suspended, or at least very much weakened, in favour of the single desire for sleep. So it is due to this partial abrogation of the censorship at night that the forbidden wishes can again become active. There are nervous people suffering from insomnia who confess that their sleeplessness was voluntary in the first instance; for they did not dare to go to sleep because they were afraid of their dreams—that is to say, they feared the consequences of the diminished vigilance of the censorship. You will have no difficulty in understanding that this curtailment of the censorship does not argue any flagrant carelessness: sleep impairs our motor functions; even if our evil intentions do begin to stir within us the utmost they can do is to produce a dream, which is for all practical purposes harmless; and it is this comforting circumstance which gives rise to the sleeper's remark, made, it is true, in the night but yet not part of his dream-life: "It is only a dream."

So we let it have its way and continue to sleep.

Thirdly, if you call to mind our idea that the dreamer striving against his own wishes is like a combination of two persons, separate and yet somehow intimately united, you will be able to understand another possible way in which something that is highly unpleasant may be brought about through wish-fulfilment: I am speaking of punishment. Here again the fairy-tale of the three wishes may help to make things clear. The sausages on the plate were the direct fulfilment of the first person's (the woman's) wish; the sausages on the tip of her nose were the fulfilment of the second person's (the husband's) wish, but at the same time they were the punishment for the foolish wish of the wife. In the neuroses we shall meet with wishes corresponding in motivation to the third wish of the fairy-tale, the only one left. There are many such punishment tendencies in the mental life of man; they are very strong and we may well regard them as responsible for some of our painful dreams. Now you will probably think that with all this there is very little of the famous wish-fulfilment left; but on closer consideration you will admit that you are wrong. In comparison with the manifold possibilities (to be discussed later) of what dreams might be—according to some writers, what they actually are—the solution: wish-fulfilment, anxiety-fulfilment, punishment-fulfilment, is surely quite a narrow one. Add to this, that anxiety is the direct opposite of a wish and that opposites lie very near one another in association and, as we have learned, actually coincide in the unconscious. Moreover, punishment itself is the fulfilment of a wish, namely, the wish of the other, censoring person.

On the whole then, I have made no concession to your objections to the wish-fulfilment theory; we are bound, however, to demonstrate its presence in any and every distorted dream, and we have certainly no desire to shirk this task. Let us go back to the dream we have already interpreted, about the three bad theatre tickets for one florin and a half, from which we have already learnt a good deal. I hope you still remember it: A lady, whose husband told her one day about the engagement of her friend Elise who was only three months younger than herself, dreamt on the following night that she and her husband were at the theatre and that one side of the stalls was almost empty. Her husband told her that Elise and her fiancé had wanted to go to the theatre too; but could not, because they could only get such bad seats,

three tickets for a florin and a half. His wife said that they had not lost much by it. We discovered that the dream-thoughts had to do with her vexation at having been in such a hurry to marry and her dissatisfaction with her husband. We may well be curious how these gloomy thoughts can have been transformed into a wish-fulfilment, and what trace of it can be found in the manifest content. Now we know already that the element *too soon, too great a hurry*, was eliminated by the censorship; the empty stalls are an allusion to this element. The puzzling phrase "*three for one florin and a half*" is now more comprehensible to us than at first, through the knowledge of symbolism that we have acquired since then.<sup>1</sup> The number *three* really stands for a man and we can easily translate the manifest element to mean: *to buy a man (husband) with the dowry*. ("I could have bought one ten times better for my dowry.") *Going to the theatre* obviously stands for marriage. *Getting the tickets too soon* is in fact a direct substitute for *marrying too soon*. Now this substitution is the work of the wish-fulfilment. The dreamer had not always felt so dissatisfied with her premature marriage as she was on the day when she heard of her friend's engagement. She had been proud of her marriage at the time and considered herself more highly favoured than her friend. One hears that naïve girls, on becoming engaged, frequently express their delight at the idea that they will now soon be able to go to all plays and see everything hitherto forbidden them.

The indication of curiosity and a desire to "look on" evinced here comes, without doubt, originally from the sexual *gazing impulse*, especially regarding the parents, and this became a strong motive impelling the girl to marry early; in this manner going to the theatre became an obvious allusive substitute for getting married. In her vexation at the present time on account of her premature marriage she therefore reverted to the time when this same marriage fulfilled a wish, by gratifying her *skoptophilia*; and so, guided by this old wish-impulse, she replaced the idea of marriage by that of going to the theatre.

We may say that the example we have chosen to demonstrate a hidden wish-fulfilment is not the most convenient one, but in all other distorted dreams we should have to proceed in a

manner analogous to that employed above. It is not possible for me to do this here and now, so I will merely express my conviction that such procedure will invariably meet with success. But I wish to dwell longer upon this point in our theory: experience has taught me that it is one of the most perilous of the whole theory of dreams, exposed to many contradictions and misunderstandings. Besides, you are perhaps still under the impression that I have already retracted part of my statement by saying that the dream may be either a wish-fulfilment, or its opposite, an anxiety or a punishment, brought to actuality; and you may think this a good opportunity to force me to make further reservations. Also I have been reproached with presenting facts that seem obvious to myself in a manner too condensed to carry conviction.

When anyone has gone as far as this in dream-interpretation and has accepted all our conclusions up to this point, it often happens that he comes to a standstill at this question of wish-fulfilment and asks: "Admitting that every dream means something and that this meaning may be discovered by employing the technique of psycho-analysis, why must it always, in face of all the evidence to the contrary, be forced into the formula of wish-fulfilment? Why must our thoughts at night be any less many-sided than our thoughts by day; so that at one time a dream might be a fulfilment of some wish, at another time, as you say yourself, the opposite, the actualization of a dread; or, again, the expression of a resolution, a warning, a weighing of some problem with its pros and cons, or a reproof, some prick of conscience, or an attempt to prepare oneself for something which has to be done—and so forth? Why this perpetual insistence upon a wish or, at the most, its opposite?"

It might be supposed that a difference of opinion on this point is a matter of no great moment, if there is agreement on all others. Cannot we be satisfied with having discovered the meaning of dreams and the ways by which we can find out the meaning? We surely go back on the advance we have made if we try to limit this meaning too strictly. But this is not so. A misunderstanding on this head touches what is essential to our knowledge of dreams and imperils its value for the understanding of neuroses. Moreover, that readiness to *oblige the other party* which has its value in business life is not only out of place but actually harmful in scientific matters.

My first answer to the question why dreams

<sup>1</sup> Another interpretation of the number *three*, occurring in the dream of this childless woman, lies very close; but I will not mention it here, because this analysis did not furnish any material illustrating it.

should not be many-sided in their meaning is the usual one in such a case: I do not know why they should not be so, and should have no objection if they were. As far as I am concerned, they can be so! But there is just one trifling obstacle in the way of this wider and more convenient conception of dreams—that as a matter of fact they are not so. My second answer would emphasize the point that to assume that dreams represent manifold modes of thought and intellectual operations is by no means a novel idea to myself: once, in the history of a pathological case, I recorded a dream which occurred three nights running and never again; and gave it as my explanation that this dream corresponded to a resolution, the repetition of which became unnecessary as soon as that resolution was carried out. Later on, I published a dream which represented a confession. How is it possible for me then to contradict myself and assert that dreams are always and only wish-fulfilments?

I do it rather than permit a stupid misunderstanding which might cost us the fruit of all our labours on the subject of dreams; a misunderstanding that *confounds the dream with the latent dream-thoughts*, and makes statements with regard to the former which are applicable to the *latter and to the latter only*. For it is perfectly true that dreams can represent, and be themselves replaced by, all the modes of thought just enumerated: resolutions, warnings, reflections, preparations or attempts to solve some problem in regard to conduct, and so on. But when you look closely, you will recognize that all this is true only of the latent thoughts which have been transformed into the dream. You learn from interpretations of dreams that the unconscious thought-processes of mankind are occupied with such resolutions, preparations and reflections, out of which dreams are formed by means of the dream-work. If your interest at any given moment is not so much in the dream-work, but centres on the unconscious thought-processes in people, you will then eliminate the dream-formation and say of dreams themselves, what is for all practical purposes correct, that they represent a warning, a resolve, and so on. This is what is often done in psycho-analytic work: generally we endeavour simply to demolish the manifest form of dreams and to substitute for it the corresponding latent thoughts in which the dream originated.

Thus it is that we learn quite incidentally from our attempt to assess the latent dream-

thoughts that all the highly complicated mental acts we have enumerated can be performed unconsciously—a conclusion surely as tremendous as it is bewildering.

But to go back a little: you are quite right in speaking of dreams as representing these various modes of thought, provided that you are quite clear in your own minds that you are using an abbreviated form of expression and do not imagine that the manifold variety of which you speak is in itself part of the essential nature of *dreams*. When you speak of a *dream* you must mean either the manifest dream, i.e., the product of the dream-work, or at most that work itself, i.e., the mental process which forms the latent dream-thoughts into the manifest dream. To use the word in any other sense is a confusion of ideas which is bound to be mischievous. If what you say is meant to apply to the latent thoughts behind the dream, then say so plainly, and do not add to the obscurity of the problem by your loose way of expressing yourselves. The latent dream-thoughts are the material which is transformed by the dream-work into the manifest dream. What makes you constantly confound the material with the process which deals with it? If you do that, in what way are you superior to those who know of the final product only, without being able to explain where it comes from or how it is constructed?

The only thing essential to the dream itself is the dream-work which has operated upon the thought-material; and when we come to theory we have no right to disregard this, even if in certain practical situations it may be neglected. Further, analytic observation shows that the dream-work never consists merely in translating the latent thoughts into the archaic or regressive forms of expression described. On the contrary, something is invariably added which does not belong to the latent thoughts of the day-time, but which is the actual motive force in dream-formation; this indispensable component being the equally unconscious *wish*, to fulfil which the content of the dream is transformed. In so far, then, as you are considering only the thoughts represented in it, the dream may be any conceivable thing—a warning, a resolve, a preparation, and so on; but besides this, it itself is always the fulfilment of an unconscious wish, and, when you regard it as the result of the dream-work, it is this alone. A dream, then, is never simply the expression of a resolve or warning, and nothing more: in it the resolve, or whatever it may be, is trans-

lated into the archaic form with the assistance of an unconscious wish, and metamorphosed in such a way as to be a fulfilment of that wish. This single characteristic, that of fulfilling a wish, is the constant one: the other component varies; it may indeed itself be a wish; in which event the dream represents the fulfilment of a latent wish from our waking hours brought about by the aid of an unconscious wish.

Now all this is quite clear to myself, but I do not know whether I have succeeded in making it equally clear to you; and it is difficult to prove it to you; for, on the one hand, proof requires the evidence afforded by a careful analysis of many dreams and, on the other hand, this, the crucial and most important point in our conception of dreams, cannot be presented convincingly without reference to considerations upon which we have not yet touched. Seeing how closely linked up all phenomena are, you can hardly imagine that we can penetrate very far into the nature of any one of them without troubling ourselves about others of a similar nature. Since as yet we know nothing about those phenomena which are so nearly akin to dreams—neurotic symptoms—we must once more content ourselves with what we actually have achieved. I will merely give you the explanation of one more example and adduce a new consideration.

Let us take once more that dream to which we have already reverted several times, the one about the three theatre tickets for one florin and a half. I can assure you that I had no ulterior motive in selecting it in the first instance for an illustration. You know what the latent thoughts were: the vexation, after hearing that her friend had only just become engaged, that she herself should have married so hastily; depreciation of her husband and the idea that she could have found a better one if only she had waited. We also know already that the wish which made a dream out of these thoughts was the desire to *look on*, to be able to go to the theatre—very probably an offshoot of an old curiosity to find out at last what really does happen after marriage. It is well known that in children this curiosity is regularly directed towards the sexual life of the parents; that is to say, it is an infantile impulse and, wherever it persists later in life, it has its roots in the infantile period. But the news received on the day previous to the dream gave no occasion for the awakening of this skoptophilia; it only roused vexation and re-

gret. This wish-impulse (of skoptophilia) was not at first connected with the latent thoughts, and the results of the dream-interpretation could have been used by the analysis without taking it into consideration at all. But again, the vexation was not in itself capable of producing a dream: no dream could be formed out of the thought: "It was folly to be in such a hurry to marry" until that thought had stirred up the early wish to see at last what happened after marriage. Then this wish formed the dream-content, substituting for marriage the going to the theatre; and the form was that of the fulfilment of the earlier wish: "Now I may go to the theatre and look at all that we have never been allowed to see; and you may not. I am married and you have got to wait." In this way the actual situation was transformed into its opposite and an old triumph substituted for the recent discomfiture; and incidentally, satisfaction both of a *gazing* impulse and of one of egoistic rivalry was brought about. It is this latter satisfaction which determines the manifest content of the dream; for in it she is actually sitting in the theatre, while her friend cannot get in. Those portions of the dream-content behind which the latent thoughts still conceal themselves are to be found in the form of inappropriate and incomprehensible modifications of the gratifying situation. The business of *interpretation* is to put aside those features in the whole which merely represent a wish fulfilment and to reconstruct the painful latent dream-thoughts from these indications.

The consideration which I said I wished to call to your notice is intended to direct your attention to these latent dream-thoughts now brought into prominence. I must beg you not to forget that, first, the dreamer is unconscious of them; secondly, that they are quite reasonable and coherent, so that we can understand them as comprehensible reactions to whatever stimulus has given rise to the dream; and, thirdly, that they may have the value of any mental impulse or intellectual operation. I will designate these thoughts more strictly now than hitherto as *the residue from the previous day*; the dreamer may acknowledge them or not. I then distinguish between this *residue* and *latent dream-thoughts* so that, as we have been accustomed to do all along, I will call everything which we learn from the interpretation of the dream *the latent dream-thoughts*, while *the residue from the previous day* is only a part of the latent dream-thoughts. Then our conception of what happens is this: something has

been added to the residue from the previous day, something which also belongs to the unconscious, a strong but repressed wish-impulse, and it is this alone which makes the formation of a dream possible. The wish-impulse, acting upon the *residue*, creates the other part of the latent dream-thoughts, that part which no longer need appear rational or comprehensible from the point of view of our waking life.

To illustrate the relation between the residue and the unconscious wish I have elsewhere made use of a comparison which I cannot do better than repeat here. Every business undertaking requires a capitalist to defray the expenses and an entrepreneur who has the idea and understands how to carry it out. Now the part of the capitalist in dream-formation is always and only played by the unconscious wish; it supplies the necessary fund of mental energy for it; the entrepreneur is the residue from the previous day, determining the manner of the expenditure. It is, of course, quite possible for the capitalist himself to have the idea and the special knowledge needed, or for the entrepreneur himself to have capital. This simplifies the practical situation but makes the theory of it more difficult. In economics we discriminate between the man in his function of capitalist and the same man in his capacity as entrepreneur; and this distinction restores the fundamental situation upon which our comparison is based. The same variations are to be found in the formation of dreams: I leave you to follow them out for yourselves.

We cannot go any further at this point; for I think it likely that a disturbing thought has long since occurred to you and it deserves a hearing. You may ask: "Is the so-called *residue* really unconscious in the sense in which the wish necessary for the formation of the dream is unconscious?" Your suspicion is justified: this is the salient point in the whole matter. They are not both unconscious in the same sense. The dream-wish belongs to a different type of UNCONSCIOUS, which, as we have seen, has its roots in the infantile period and is furnished with special mechanisms. It is very expedient to distinguish the two types of *unconscious* from one another by speaking of them in different terms. But, all the same, we will rather wait until we have familiarized ourselves with the phenomena of the neuroses. If our conception of the existence of any kind of unconscious be already regarded as fantastic, what will people say if we admit that to reach our solution we have had to assume two kinds?

Let us break off at this point. Once more you have heard only an incomplete statement; but is it not a hopeful thought that this knowledge will be carried further, either by ourselves or by those who come after us? And have not we ourselves learnt enough that is new and startling?

## FIFTEENTH LECTURE

### DOUBTFUL POINTS AND CRITICAL OBSERVATIONS

We will not leave the subject of dreams without dealing with the most common doubts and uncertainties arising in connection with the novel ideas and conceptions we have been discussing: those of you who have followed these lectures attentively will have collected some material of the kind.

1. You may have received an impression that even with strict adherence to technique our work of dream-interpretation leaves so much room for uncertainty that reliable translation of manifest dreams into their latent dream-thoughts will be thereby frustrated. You will urge first that one never knows whether any particular element in a dream is to be understood literally or symbolically, since things employed as symbols do not thereby cease to be themselves. Where there is no objective evidence to decide the question the interpretation on that particular point will be left to be arbitrarily determined by the interpreter. Further, since in the dream-work opposites coincide, it is in every instance uncertain whether a specific dream-element is to be understood in a positive or a negative sense, as itself or as its opposite—another opportunity for the interpreter to exercise a choice. Thirdly, on account of the frequency with which inversion of every kind is employed in dreams, it is open to him to assume whenever he chooses that such an inversion has taken place. Finally you will point to having heard that one is seldom certain that the interpretation arrived at is the only possible one, and that there is danger of overlooking another perfectly admissible interpretation of the same dream. In these circumstances, you will conclude, the discretion of the interpreter has a latitude that seems incompatible with any objective certainty in the result. Or you may also assume that the fault does not lie in dreams themselves, but that something erroneous in our conceptions and premises produces the unsatisfactory character of our interpretations.

All that you say is undeniable and yet I do not think it justifies either of your conclusions: that dream-interpretation as practised by us is at the mercy of the interpreter's arbitrary decisions or that the inadequacy of the results calls in question the correctness of our procedure. If for the *arbitrary decision* of the interpreter you will substitute his skill, his experience and his understanding, then I am with you. This kind of personal factor is of course indispensable, especially when interpretation is difficult; it is just the same in other scientific work, however; it can't be helped that one man will use any given technique less well, or apply it better, than another. The impression of arbitrariness made, for example, by the interpretation of symbols is corrected by the reflection that as a rule the connection of the dream-thoughts with one another, and of the dream with the life of the dreamer and the whole mental situation at the time of the dream, points directly to one of all the possible interpretations and renders all the rest useless. The conclusion that the imperfect character of the interpretations proceeds from fallacious hypotheses loses its force when consideration shows that, on the contrary, the ambiguity or indefiniteness of dreams is a quality which we should necessarily expect in them.

Let us call to mind our statement that the dream-work undertakes a translation of the dream-thoughts into a primitive mode of expression, analogous to hieroglyphics. Now all such primitive systems of expression are necessarily accompanied by ambiguity and indefiniteness; but we should not on that account be justified in doubting their practicability. You know that the coincidence of opposites in the dream-work is analogous to what is called the antithetical sense of primal words in the oldest languages. The philologist, R. Abel, to whom we owe this information, writing in 1884, begs us not on any account to imagine that there was any ambiguity in what one person said to another by means of ambivalent words of this sort. On the contrary, intonation, gestures and the whole context can have left no doubt whatever which of the two opposites the speaker had in mind to convey. In writing where gestures are absent the addition of little pictorial signs, not meant to receive separate oral expression, replaced them: e.g., a drawing of a little man, either crouching or standing upright, according as the ambiguous *ken* of the hieroglyphic meant *weak* or *strong*. So that mis-

understanding was avoided in spite of the ambiguity of sounds and signs.

In ancient systems of expression, for instance, in the scripts of the oldest languages, indefiniteness of various kinds is found with a frequency which we should not tolerate in our writings today. Thus in many Semitic writings only the consonants of the words appear: the omitted vowels have to be supplied by the reader from his knowledge and from the context. Hieroglyphic writing follows a similar principle, although not exactly the same; and this is the reason why nothing is known of the pronunciation of ancient Egyptian. There are besides other kinds of indefiniteness in the sacred writings of the Egyptians: for example, it is left to the writer's choice to inscribe the pictures from right to left or from left to right. To be able to read them, we have to remember that we must be guided by the direction of the faces of the figures, birds, and so forth. But it was also open to the writer to set the pictures in vertical columns and, in the case of inscriptions on smaller objects, he was led by considerations of what was pleasing to the eye, and of the space at his disposal, to introduce still further alterations in the arrangement of the signs. The most confusing feature in hieroglyphic script is that there is no spacing between the words. The pictures are all placed at equal intervals on the page, and it is generally impossible to know whether any given sign goes with the preceding one or forms the beginning of a new word. In Persian cuneiform writing, on the other hand, a slanting sign is used to separate the words.

The Chinese language, both spoken and written, is exceedingly ancient but is still used today by four hundred million people. Don't suppose that I understand it at all; I only obtained some information about it because I hoped to find in it analogies to the kinds of indefiniteness occurring in dreams; nor was I disappointed in my expectation, for Chinese is so full of uncertainties as positively to terrify one. As is well known, it consists of a number of syllabic sounds which are pronounced singly or doubled in combination. One of the chief dialects has about four hundred of these sounds, and since the vocabulary of this dialect is estimated at somewhere about four thousand words it is evident that every sound has an average of ten different meanings—some fewer, but some all the more. For this reason there are a whole series of devices to escape ambiguity, for the context alone will not show

which of the ten possible meanings of the syllable the speaker wishes to convey to the hearer. Amongst these devices is the combining of two sounds into a single word and the use of four different "tones" in which these syllables may be spoken. For purposes of our comparison a still more interesting fact is that this language is practically without grammar: it is impossible to say of any of the one-syllable words whether it is a noun, a verb or an adjective; and, further there are no inflections to show gender, number, case, tense or mood. The language consists, as we may say, of the raw material only; just as our thought-language is resolved into its raw material by the dream-work omitting to express the relations in it. Wherever there is any uncertainty in Chinese the decision is left to the intelligence of the listener, who is guided by the context. I made a note of a Chinese saying, which literally translated runs thus: "Little what see, much what wonderful." This is simple enough to understand. It may mean: "The less a man has seen, the more he finds to wonder at," or "There is much to wonder at for the man who has seen little." Naturally there is no occasion to choose between these two translations which differ only in grammatical construction. We are assured that in spite of these uncertainties the Chinese language is a quite exceptionally good medium of expression; so it is clear that indefiniteness does not necessarily lead to ambiguity.

Now we must certainly admit that the position of affairs is far less favourable in regard to the mode of expression in dreams than it is with these ancient tongues and scripts; for these latter were originally designed as a means of communication; that is, they were intended to be understood, no matter what ways or means they had to employ. But just this character is lacking to dreams: their object is not to tell anyone anything; they are not a means of communication; on the contrary, it is important to them not to be understood. So we ought not to be surprised or misled if the result is that a number of the ambiguities and uncertainties in dreams cannot be determined. The only certain piece of knowledge gained from our comparison is that this indefiniteness (which people would like to make use of as an argument against the accuracy of our dream-interpretations) is rather to be recognized as a regular characteristic of all primitive systems of expression.

Practice and experience alone can determine

the extent to which dreams can in actual fact be understood. My own opinion is that this is possible to a very great extent; and a comparison of the results obtained by properly trained analysts confirms my view. It is well known that the lay public, even in scientific circles, delights to make a parade of superior scepticism in the face of the difficulties and uncertainties which beset a scientific achievement; I think they are wrong in so doing. You may possibly not all know that the same thing happened at the time when the Babylonian and Assyrian inscriptions were being deciphered. There was a point at which public opinion was active in declaring that the men deciphering the cuneiform writing were victims of a chimera and that the whole business of investigation was a fraud. But in the year 1857 the Royal Asiatic Society made a conclusive test. They challenged four of the most distinguished men engaged in this branch of research—Rawlinson, Hincks, Fox Talbot and Oppert—to send to the Society in sealed envelopes independent translations of a newly discovered inscription, and, after comparing the four versions, they were able to announce that there was sufficient agreement between the four to justify belief in what had been achieved and confidence in further progress. The mockery of the learned laity then gradually came to an end, and certainty in the reading of cuneiform documents has advanced enormously since then.

2. A second series of objections is closely connected with an impression which you also have probably not escaped; namely, that a number of the solutions achieved by our method of dream-interpretation seem strained, specious, *dragged in*—in other words, forced, or even comical or joking. These criticisms are so frequent that I will take at random the last that has come to my ears. Now listen: a head-master in Switzerland—that free country—was recently asked to resign his post on account of his interest in psycho-analysis. He protested and a Berne paper published the decision of the school authorities on his case. I shall quote from the article a few sentences which refer to psycho-analysis: "Further, we are amazed at the far-fetched and factitious character of many of the examples given in the said book by Dr. Pfister of Zurich. . . . It is indeed a matter for surprise that the head-master of a Training College should accept so credulously all these assertions and such specious evidence." These sentences purport to be the final opinion

of "One who judges calmly." I am much more inclined to think this "calm" factitious. Let us examine these remarks more closely in the expectation that a certain amount of reflection and knowledge of the subject will do no harm, even to a "calm judgment."

It is really quite refreshing to see how swiftly and unerringly anyone relying merely on his first impressions can arrive at an opinion on some critical question of psychology in its more abstruse aspects. The interpretations seem to him far-fetched and strained, and do not commend themselves to him; consequently, they are wrong and the whole business is rubbish. Such critics never give even a passing thought to the possibility that there may be good reasons why the interpretations are bound to convey this very impression—a thought which would lead to the further question what these good reasons are.

The circumstance which calls forth this criticism is essentially related to the effect of displacement, which you have learnt to know as the most powerful instrument in the service of the dream-censorship. With its aid the substitute-formations which we call allusions are created; but these allusions are of a kind not easy to recognize as such; nor is it easy to discover the thought proper by working back from them, for they are connected with it by the most extraordinary and unusual extrinsic associations. But the whole matter throughout concerns things which are meant to be hidden, intended to be concealed: that is exactly the object of the dream-censorship. We must not expect, though, to find something that has been hidden by looking in the very place where it ordinarily belongs. The frontier surveillance authorities nowadays are a good deal more cunning in this respect than the Swiss school authorities; for they are not content with examining portfolios and letter-cases when hunting for documents and plans; but consider the possibility that spies and smugglers may conceal anything compromising about their persons, in places where it is most difficult to detect and where such things certainly do not belong, for example, between the double soles of their boots. If the concealed articles are found there, it is certainly true that they have been *dragged* to light, but they are none the less a very good *find*.

In admitting the possibility that the connection between a latent dream-element and its manifest substitute may appear most remote and extraordinary, sometimes even comical or

joking, we are guided by our wide experience of instances in which we did not as a rule find the meaning ourselves. It is often impossible to arrive at such interpretations by our own efforts: no sane person could guess the bridge connecting the two. The dreamer either solves the riddle straightaway by a direct association (*he* can do it because it is in his mind that the substitute-formation originated); or else he provides so much material that there is no longer any need for special penetration in order to solve it—the solution thrusts itself upon us as inevitable. If the dreamer does not help us in either of these two ways the manifest element in question will remain for ever incomprehensible. Let me give you one more instance of this kind which happened recently. A patient of mine lost her father during the course of the treatment, after which she seized every opportunity to bring him back to life in her dreams. In one of these her father appeared in a certain connection otherwise not applicable and said: "*It is quarter past eleven, it is half past eleven, it is quarter to twelve.*" For the interpretation of this curious detail she could only provide the association that her father was pleased when his older children were punctual at the midday meal. This certainly fitted in with the dream-element, but it threw no light on its origin. The situation which had just been reached in the treatment gave good grounds for the suspicion that a carefully suppressed critical antagonism to her much loved and honoured father had played a part in this dream. Following out her further associations, apparently quite remote from the dream, she told how she had heard a long discussion of psychological questions on the day before and a relative had said: "Primitive man (*Urmensch*) survives in all of us." Now a light dawns on us. Here was again a splendid opportunity for her to imagine that her dead father survived, and so in the dream she made him a "clock-man" (*Uhrmensch*), telling the quarters up to the time of the midday meal.

The likeness to a pun in this cannot be ignored, and as a matter of fact it has often happened that a dreamer's pun has been ascribed to the interpreter; there are yet other examples in which it is not at all easy to decide whether we are dealing with a joke or a dream. But you will remember that the same sort of doubt arose with some slips of the tongue. A man related as a dream that he and his uncle were sitting in the latter's *auto* (automobile) and his uncle kissed him. The dreamer himself

instantly volunteered the interpretation: it meant *auto-erotism* (a term used in our theory of the libido, signifying gratification obtained without any external love-object). Now was this man allowing himself a joke at our expense and pretending that a pun which occurred to him was part of a dream? I do not think so: he really did dream it. But where does this bewildering resemblance between dreams and jokes come from? At one time this question took me somewhat out of my way, for it necessitated my making a thorough investigation into the question of wit itself. This led to the conclusion that wit originates as follows: a preconscious train of thought is for a moment left to a process of unconscious elaboration, from which it emerges in the form of a witticism. While under the influence of the unconscious it is subject to the mechanisms there operative—to condensation and displacement; that is to say, to the same processes as we found at work in the dream-work; and the similarity sometimes found between dreams and wit is to be ascribed to this character common to both. But the unintentional *dream-joke* does not amuse us as does an ordinary witticism; a deeper study of wit may show you why this is so. The *dream-joke* strikes us as a poor form of wit; it does not make us laugh, it leaves us cold.

Now in this we are following the path of the ancient method of dream-interpretation, which has given us, besides much that is useless, many a valuable example of interpretation upon which we ourselves could not improve. I will tell you a dream of historic importance which is related in slightly different versions by Plutarch and Artemidorus of Daldis, the dreamer being Alexander the Great. When he was laying siege to the city of Tyre, which was putting up an obstinate resistance (B.C. 322), he dreamt one night that he saw a dancing satyr. The dream-interpreter Aristandros, who accompanied the army on its campaigns, interpreted this dream by dividing the word *satyrōs* into Σά Τύρος (Tyre is thine), and prophesied from this the king's victory over the city. This interpretation decided Alexander to continue the siege and eventually the city fell. The interpretation, factitious as it seems, was undoubtedly the right one.

3. I can well imagine that you will be especially impressed on being told that even people who have long studied the interpretation of dreams in the course of their work as psycho-analysts have raised objections to our

conception of dreams. It would indeed have been exceptional if so excellent an opportunity for new mistakes had been let slip; and so assertions have been made, due to confusion of ideas and based on unjustifiable generalizations, which are hardly less incorrect than the medical conception of dreams. One of these statements you know already: that dreams deal with attempts at adaptation to the situation at the moment and with the solution of future problems; in other words, that they pursue a "prospective tendency" or aim (A. Maeder). We have already demonstrated that this statement rests upon a confusion between dreams and the latent dream-thoughts and ignores the process of dream-work. If those who speak of this "prospective tendency" mean thereby to characterize the unconscious mental activity to which the latent thoughts belong, then, on the one hand, they tell us nothing new and, on the other hand, the description is not exhaustive; for the unconscious mental activity occupies itself with many other things besides preparation for the future. There seems to be a much worse confusion behind the assurance that the *death clause* may be found underlying every dream; I am not quite clear what this formula is intended to mean, but I suspect that behind it the dream is confounded with the whole personality of the dreamer.

An unjustifiable generalization, based on a few striking examples, is contained in the statement that every dream admits of two kinds of interpretation: one of the kind we have described, the so-called *psycho-analytic* interpretation, and the other the so-called *anagogic*, which disregards the instinctual tendencies and aims at a representation of the higher mental functions (H. Silberer); there are dreams of this kind, but you will seek in vain to extend this conception to include even a majority of dreams. After all you have heard, the statement that all dreams are to be interpreted bisexually, as a combination of two tendencies which may be called male and female (A. Adler), will seem to you quite incomprehensible. Here again, single dreams of this sort do of course occur and later on you may learn that their structure is similar to that of certain hysterical symptoms. I mention all these discoveries of new general characteristics of dreams in order to warn you against them, or at least to leave you in no doubt about my own opinion of them.

4. At one time the objective value of research

into dreams seemed to be discredited by the fact that patients treated analytically appeared to suit the content of their dreams to the favourite theories of their doctors, one class dreaming mainly of sexual impulses, and another of impulses for mastery, others again even of rebirth (W. Stekel). The force of this observation is weakened by the reflection that people dreamed dreams before there was any such thing as psycho-analytic treatment to influence their dreams and that the patients undergoing treatment nowadays also used to dream before they began it. The actual fact in this supposedly new observation is soon shown to be self-evident and of no consequence for the theory of dreams. The residue from the previous day which gives rise to dreams is a residue from the great interests of waking life. If the physician's words and the stimuli which he gives have become of importance to the patient they then enter into whatever constitutes the residue and can act as mental stimuli for dream-formation, just like other interests of affective value roused on the preceding day which have not subsided; they operate in the same way as bodily stimuli which affect the sleeper during sleep. Like these other factors inciting dreams, the trains of thought roused by the physician can appear in the manifest dream-content or be revealed in the latent thoughts. We know indeed that dreams can be experimentally produced, or, to speak more accurately, a part of the dream-material can be thus introduced into the dream. In influencing his patients thus the analyst plays a part no different from that of an experimenter, like Mourly Vold, who placed in certain positions the limbs of the person upon whom he experimented.

We can often influence what a man shall dream *about*, but never *what* he will dream; for the mechanism of the dream-work and the unconscious dream-wish are inaccessible to external influence of any sort. We realized, when we were considering dreams arising out of bodily stimuli, that in the reaction to the bodily or mental stimuli brought to bear upon the dreamer the peculiarity and independence of dream-life is clearly seen. The criticism I have

just discussed which tends to cast a doubt upon the objectivity of dream investigation is again an assertion based upon confounding, this time confounding dreams with—their material.

I wanted to tell you as much as this about the problems of dreams. You will guess that I have passed over a great deal and will have discovered for yourselves that my treatment of nearly every point has necessarily been incomplete; but this is due to the phenomena of dreams being so closely connected with those of the neuroses. Our plan was to study dreams as an introduction to the study of the neuroses and it was certainly a better one than beginning the other way about; but since dreams prepare us for comprehension of the neuroses, so also can a correctly formed estimate of dreams be acquired only after some knowledge of neurotic manifestations has been gained.

I do not know how you may think about it, but I can assure you that I do not regret having taken up so much of your interest and of the time at our disposal in the consideration of problems connected with dreams. I know no other way by which one can so speedily arrive at conviction of the correctness of those statements by which psycho-analysis stands or falls. It requires strenuous work for many months, and even years, to demonstrate that the symptoms in a case of neurotic illness have a meaning, serve a purpose, and arise from the patient's experiences in life. On the other hand, a few hours' effort may be enough to show these things in some dream which at first seemed utterly confused and incomprehensible, and in this way to confirm all the premises upon which psycho-analysis rests—the existence of unconscious mental processes, the special mechanisms which they obey, and the instinctive propelling forces which are expressed by them. And when we remember how far-reaching is the analogy in the structure of dreams to that of neurotic symptoms and, with that, reflect how rapid is the transformation of a dreamer into a wide-awake, reasonable human being, we acquire an assurance that the neuroses too depend only upon an alteration in the balance of the forces at work in mental life.

## PART III. GENERAL THEORY OF NEUROSES

## SIXTEENTH LECTURE

## PSYCHO-ANALYSIS AND PSYCHIATRY

It pleases me greatly to see you here again, to continue our discussions after a year has passed. Last year the subject of my lectures was the application of psycho-analysis to errors and to dreams; I hope this year to lead you to some comprehension of neurotic phenomena which, as you will soon discover, have much in common with both our former subjects. I must tell you before I begin, however, that I cannot concede you the same attitude towards me now as I did last year. Then I endeavoured to make no step without being in agreement with your judgment; I debated a great deal with you, submitted to your objections, in fact, recognized you and your *healthy common sense* as the deciding factor. That is no longer possible and for a very simple reason. Errors and dreams are phenomena which were familiar to you; one might say you had as much experience of them as I, or could easily have obtained it. The manifestations of neurosis, however, are an unknown region to you; those of you who are not yourselves medical men have no access there except through the accounts I give you; and of what use is the most excellent judgment where there is no knowledge of the subject under debate?

However, do not receive this announcement as though I were going to give these lectures *ex cathedra* or to demand unconditional acceptance from you. Any such misconception would do me a gross injustice. I do not aim at producing conviction—my aim is to stimulate enquiry and to destroy prejudices. If, owing to ignorance of the subject, you are not in a position to adjudicate, then you should neither believe nor reject. You should only listen and allow what I tell you to make its own effect upon you. Convictions are not so easily acquired, or, when they are achieved without much trouble, they soon prove worthless and unstable. No one has a right to conviction on these matters who has not worked at this subject for many years, as I have, and has not himself experienced the same new and astonishing discoveries. Then why these sudden convictions in intellectual matters, lightning conversions, and instantaneous repudiations? Do you not see that the *coup de foudre*, love

at first sight, proceeds from a very different mental sphere, from the affective one? We do not require even our patients to bring with them any conviction in favour of psycho-analysis or any devotion to it. It would make us suspicious of them. Benevolent scepticism is the attitude in them which we like best. Therefore will you also try to let psycho-analytical conceptions develop quietly in your minds alongside the popular or the psychiatric view, until opportunities arise for them to influence each other and be united into a decisive opinion.

On the other hand, you are not for a moment to suppose that the psycho-analytic point of view which I shall lay before you is a speculative system of ideas. On the contrary, it is the result of experience, being founded either on direct observations or on conclusions drawn from observation. Whether these have been drawn in an adequate or a justifiable manner future advances in science will show; after nearly two and a half decades and now that I am fairly well advanced in years I may say, without boasting, that it was particularly difficult, intense, and all-absorbing work that yielded these observations. I have often had the impression that our opponents were unwilling to consider this source of our statements, as if they looked upon them as ideas derived subjectively which anyone could dispute at his own sweet will. This attitude on the part of my opponents is not quite comprehensible to me. Perhaps it comes from the circumstance that physicians pay so little attention to neurotics and listen so carelessly to what they say that it has become impossible for them to perceive anything in the patients' communications or to make detailed observations from them. I will take this opportunity of assuring you that in these lectures I shall make few controversial references, least of all to individuals. I have never been able to convince myself of the truth of the saying that "strife is the father of all things." I think the source of it was the philosophy of the Greek sophists and that it errs, as does the latter, through the overestimation of dialectics. It seems to me, on the contrary, that scientific controversy, so-called, is on the whole quite unfruitful, apart from the fact that it is almost always conducted in a highly personal manner. Until a few years

ago I could boast that I had only once been engaged in a regular scientific dispute, and that with one single investigator, Löwenfeld of Munich. The end of it was that we became friends and have remained so to this day. But I did not repeat the experiment for a very long time because I was not certain that the outcome would be the same.

Now you will surely judge that a refusal of this kind to discuss matters publicly points to a high degree of inaccessibility to criticism, to obstinacy, or, in the polite colloquialism of the scientific world, to *pig-headedness*. My reply to you would be that, should you have arrived at a conviction by means of such hard work, you would also thereby derive a certain right to maintain it with some tenacity. Further, on my own behalf, I can say that in the course of my work I have modified my views on important points, changed them or replaced them by others, and have of course in each case published the fact. What has been the result of this frankness? Some people have ignored my corrections of myself altogether and still today criticize me in respect of views which no longer mean the same to me. Others positively reproach me for these changes and declare me to be unreliable on that account. No one who changes his views once or twice deserves to be believed, for it is only too likely that he will be mistaken again in his latest assertions; but anyone who sticks to anything he has once said, or refuses to give way upon it easily enough, is obstinate or pig-headed; is it not so? What is to be done in the face of these self-contradictory criticisms except to remain as one is and behave as seems best to one? This is what I decided to do; and I am not deterred from remodelling and improving my theories in accordance with later experience. I have so far found nothing to alter in my fundamental standpoint and I hope this will never be necessary.

So now I have to lay before you the psycho-analytic theory of neurotic manifestations. For this purpose it will be simplest, on account of both the analogy and the contrast, to take an example which links up with the phenomena we have already considered. I will take a *symptomatic act* which I see many people commit in my own consulting-room. The analyst has little to offer to the people who come to a physician's consulting-room for half-an-hour to recount the lifelong misery of their fate. His deeper comprehension makes it difficult for him to give, as another might, the opinion that there

is nothing wrong with them and that they had better take a light course of hydro therapy. One of our colleagues once replied, with a shrug, when asked how he dealt with consultation patients, that he "fined them so many crowns for 'wasting the time of the court.'" You will, therefore, not be surprised to hear that even the busiest psycho-analysts are not much sought after for consultations. I have had the ordinary door between the waiting-room and my consulting-room supplemented by another door and covered with felt. The reason for this is obvious. Now it constantly happens when I admit people from the waiting-room that they omit to close these doors, leaving even both doors open behind them. When I see this happen, I at once, with some stiffness, request him or her to go back and make good the omission, no matter how fine a gentleman he may be or how many hours she has spent on her toilet. My action gives the impression of being uncalled for and pedantic; occasionally too I have found myself in the wrong, when the person turned out to be one of those who cannot themselves grasp a door-handle and are glad when those with them avoid it. But in the majority of cases I was right, for anyone who behaves in this way and leaves the door of a physician's consulting-room open into the waiting-room belongs to the rabble and deserves to be received with coldness. Now don't allow yourselves to be biased before you have heard the rest. This omission on the part of a patient occurs only when he has been waiting alone in the outer room and thus leaves an empty room behind him, never when others, strangers to him, have also been waiting there. In the latter case he knows very well that it is to his own interest not to be overheard while he talks to the physician and he never neglects to close both doors carefully.

Ocurring in this way, the patient's omission is neither accidental nor meaningless, and not even unimportant, for it betrays the visitor's attitude to the physician. He belongs to that large class who seek those in high places, and wish to be dazzled and intimidated. Perhaps he had made enquiries by telephone at what time he would be most likely to gain admittance and had been expecting to find a crowd of applicants in a queue, as if at the grocer's in war-time. Then he is shown into an empty room which, moreover, is most modestly furnished, and he is dumbfounded. He must somehow make the physician atone for the superfluous respect he had been prepared to show him;

and so he omits to close the doors between the waiting- and the consulting-rooms. He intends this to mean: "Pooh! there is no one here and I daresay there won't be, however long I stay!" He would behave during the interview in an uncivil and supercilious manner, too, if his presumption were not curbed at the outset by a sharp reminder.

In the analysis of this little symptomatic act you find nothing that is not already known to you; namely, the conclusion that it is no accident but has in it motive, meaning, and intention; that it belongs to a mental context which can be specified; and that it provides a small indication of a more important mental process. But above all it implies that the process thus indicated is not known to the consciousness of the person who carries it out; for not one of the patients who left the two doors open would have admitted that he wished to show any depreciation of me by his neglect. Many of them could probably recall a sense of disappointment on entering the empty waiting-room, but the connection between this impression and the succeeding symptomatic act certainly remained outside their consciousness.

Now let us place this little analysis of a symptomatic act by the side of an observation made on a patient. I will choose one which is fresh in my memory, and also because it can be described in comparatively few words. A certain amount of detail is indispensable for any such account.

A young officer, home on short leave of absence, asked me to treat his mother-in-law, who was living in the happiest surroundings and yet was embittering her own and her family's lives by a nonsensical idea. I found her a well-preserved lady, fifty-three years of age, of a friendly, simple disposition, who gave without hesitation the following account of herself. She is most happily married, and lives in the country with her husband who manages a large factory. She cannot say enough of her husband's kindness and consideration; theirs had been a love-marriage thirty years ago, since when they had never had a cloud, a quarrel, or a moment's jealousy. Her two children have both married well, but her husband's sense of duty keeps him still at work. A year before, an incredible and, to her, incomprehensible thing happened. She received an anonymous letter telling her that her excellent husband was carrying on an intrigue with a young girl, and believed it on the spot—since then her happiness has been destroyed. The details were more or

less as follows: she had a housemaid with whom she discussed confidential matters, perhaps rather too freely. This young woman cherished a positively venomous hatred for another girl who had succeeded better in life than herself, although of no better origin. Instead of going into service, the other young woman had had a commercial training, been taken into the factory and, owing to vacancies caused by the absence of staff on service in the field, had been promoted to a good position. She lived in the factory, knew all the gentlemen, and was even addressed as "Miss." The other one who had been left behind in life was only too ready to accuse her former schoolmate of all possible evil. One day our patient and her housemaid were discussing an elderly gentleman who had visited the house and of whom it was said that he did not live with his wife but kept a mistress. Why, she did not know, but she suddenly said: "I cannot imagine anything more awful than to hear that my husband had a mistress." The next day she received by post an anonymous letter in disguised handwriting which informed her of the very thing she had just imagined. She concluded—probably correctly—that the letter was the handiwork of her malicious housemaid, for the woman who was named as the mistress of her husband was the very girl who was the object of this housemaid's hatred. Although she at once saw through the plot and had seen enough of such cowardly accusations in her own surroundings to place little credence in them, our patient was nevertheless prostrated by this letter. She became terribly excited and at once sent for her husband to overwhelm him with reproaches. The husband laughingly denied the accusation and did the best thing he could. He sent for the family physician (who also attended the factory), and he did his best to calm the unhappy lady. The next thing they did was also most reasonable. The housemaid was dismissed, but not the supposed mistress. From that time on the patient claims to have repeatedly brought herself to a calm view of the matter, so that she no longer believes the contents of the letter; but it has never gone very deep nor lasted very long. It was enough to hear the young woman's name mentioned, or to meet her in the street, for a new attack of suspicion, agony, and reproaches to break out.

This is the clinical picture of this excellent woman's case. It did not require much experience of psychiatry to perceive that, in contrast to other neurotics, she described her symptoms

too mildly—as we say, dissimulated them—and that she had never really overcome her belief in the anonymous letter.

Now what attitude does a psychiatrist take up to such a case? We know already what he would say to the symptomatic act of a patient who does not close the waiting-room doors. He explains it as an accident, without interest psychologically, and no concern of his. But he cannot continue to take up this attitude in regard to the case of the jealous lady. The symptomatic action appears to be unimportant; the symptom calls for notice as a grave matter. Subjectively it involves intense suffering, and objectively it threatens to break up a family; its claim to psychiatric interest is therefore indisputable. First the psychiatrist tries to characterize the symptom by some essential attribute. The idea with which this lady torments herself cannot be called nonsensical in itself; it does happen that elderly husbands contract relationships with young women. But there is something else about it that is nonsensical and incomprehensible. The patient has absolutely no grounds, except the anonymous letter, for supposing that her loving and faithful husband belongs to this category of men, otherwise not so uncommon. She knows that this communication carries no proof, she can explain its origin satisfactorily; she ought therefore to be able to say to herself that she has no grounds for her jealousy and she does even say so, but she suffers just as much as if she regarded her jealousy as well-founded. Ideas of this kind that are inaccessible to logic and the arguments of reality are unanimously described as *delusions*. The good lady suffers therefore, from a *delusion of jealousy*. That is evidently the essential characteristic of the case.

Having established this first point, our psychiatric interest increases. When a delusion cannot be dissipated by the facts of reality, it probably does not spring from reality. Where else then does it spring from? Delusions can have the most various contents; why is the content of it in this case jealousy? What kind of people have delusions, and particularly delusions of jealousy? Now we should like to listen to the psychiatrist, but he leaves us in the lurch here. He considers only one of our questions. He will examine the family history of this woman and will *perhaps* bring us the answer that the kind of people who suffer from delusions are those in whose families similar or different disorders have occurred repeatedly.

In other words, this lady has developed a delusion because she had an hereditary predisposition to do so. That is certainly something; but is it all that we want to know? Is it the sole cause of her disease? Does it satisfy us to assume that it is unimportant, arbitrary, or inexplicable that one kind of delusion should have been developed instead of another? And are we to understand the proposition—that the hereditary predisposition is decisive—also in a negative sense; that is, that no matter what experiences and emotions life had brought her she was destined some time or other to produce a delusion? You will want to know why scientific psychiatry gives no further explanation. And I reply: “Only a rogue gives more than he has.” The psychiatrist knows of no path leading to any further explanation in such a case. He has to content himself with a diagnosis and, in spite of wide experience, with a very uncertain prognosis of its future course.

Now can psycho-analysis do better than this? Yes, certainly I hope to show you that even in such an obscure case as this it is possible to discover something which makes closer comprehension possible. First, I shall ask you to notice this incomprehensible detail; that the anonymous letter on which her delusion is founded was positively provoked by the patient herself, by her saying to the scheming housemaid the day before that nothing could be more awful than to hear that her husband had an intrigue with a young woman. She first put the idea of sending the letter into the servant's mind by this. So the delusion acquires a certain independence of the letter; it existed beforehand as a fear—or, as a wish?—in her mind. Besides this, the further small indications revealed in the bare two hours of analysis are noteworthy. The patient responded very coldly, it is true, to the request to tell me her further thoughts, ideas, and recollections, after she had finished her story. She declared that nothing came to her mind, she had told me everything; and after two hours the attempt had to be given up, because she announced that she felt quite well already and was certain that the morbid idea would not return. Her saying this was naturally due to resistance and to the fear of further analysis. In these two hours she had let fall some remarks, nevertheless, which made a certain interpretation not only possible but inevitable, and this interpretation threw a sharp light on the origin of the delusion of jealousy. There actually existed in her an infatuation for a young man, for the very son-in-law who had

urged her to seek my assistance. Of this infatuation she herself knew nothing or only perhaps very little; in the circumstances of their relationship it was easily possible for it to disguise itself as harmless tenderness on her part. After what we have already learnt it is not difficult to see into the mind of this good woman and excellent mother. Such an infatuation, such a monstrous, impossible thing, could not come into her conscious mind; it persisted, nevertheless, and unconsciously exerted a heavy pressure. Something had to happen, some sort of relief had to be found; and the simplest alleviation lay in that mechanism of displacement which so regularly plays its part in the formation of delusional jealousy. If not merely she, old woman that she was, were in love with a young man, but if only her old husband too were in love with a young mistress, then her torturing conscience would be absolved from the infidelity. The phantasy of her husband's infidelity was thus a cooling balm on her burning wound. Of her own love she never became conscious; but its reflection in the delusion, which brought such advantages, thus became compulsive, delusional and conscious. All arguments against it could naturally avail nothing; for they were directed only against the reflection, and not against the original to which its strength was due and which lay buried out of reach in the unconscious.

Let us now piece together the results of this short, obstructed psycho-analytic attempt to understand this case. It is assumed, of course, that the information acquired was correct, a point which I cannot submit to your judgment here. First of all, the delusion is no longer senseless and incomprehensible; it is sensible, logically motivated, and has its place in connection with an affective experience of the patient's. Secondly, it has arisen as a necessary reaction to another mental process which has itself been revealed by other indications; and it owes its delusional character, its quality of resisting real and logical objections, to this relation with this other mental process. It is something desired in itself, a kind of consolation. Thirdly, the fact that the delusion is one of jealousy and no other is unmistakably determined by the experience underlying the disease. You will also recognize the two important analogies with the symptomatic act we analysed; namely, the discovery of the sense or intention behind the symptom and the relation of it to something in the given situation which is unconscious.

This does not, of course, answer all the questions arising out of this case. On the contrary, it bristles with further problems, some of which have not yet proved soluble at all, while others cannot be solved owing to the unfavourable circumstances met with in this case. For instance, why does this happily married lady fall in love with her son-in-law, and why does relief come to her in the form of this kind of reflection, this projection of her own state of mind on to her husband, when other forms of relief were also possible? Do not think that it is idle and uncalled for to propound these questions. We have already a good deal of material at hand to provide possible answers. The patient had come to that critical time of life which brings a sudden and unwelcome increase of sexual desire to a woman; that may have been sufficient in itself. Or there may have been an additional reason, in that the sexual capacity of her excellent and faithful husband may have been for some years insufficient for the still vigorous woman's needs. Observation has taught us that it is just such men, whose fidelity is thus a matter of course, who treat their wives with particular tenderness and are unusually considerate of their nervous ailments. Neither is it unimportant, moreover, that the object of this abnormal infatuation should be her daughter's young husband. A strong erotic attachment to the daughter, with its roots in the individual sexual constitution of the mother, often manages to maintain itself in such a transformation. I may perhaps remind you in this connection that the relation between mother-in-law and son-in-law has from time immemorial been regarded by mankind as a particularly sensitive one, which among primitive races has given rise to very powerful taboos and precautions.<sup>1</sup> On the positive as well as on the negative side it frequently exceeds the limits regarded as desirable in civilized society. Of these three possible factors, whether one of them has been at work in the case before us, or two of them, or whether all three together have taken part, I cannot tell you; though only because the analysis of the case could not be continued beyond the second hour.

I perceive now that I have been speaking entirely of things which you were not yet prepared to understand. I did so in order to carry out the comparison between psychiatry and psychoanalysis. But I may ask you one thing at this point: Have you observed anything in the nature of a contradiction between the two? Psy-

<sup>1</sup> Cf. *Totem and Taboo*.

chiatry does not employ the technical methods of psycho-analysis, neglects any consideration of the content of the delusion, and in pointing to heredity gives us but a general and remote aetiology instead of first disclosing the more scientific and immediate one. But is any contradiction or opposition contained in this? Is not the one rather a supplement to the other? Is the hereditary factor inconsistent with the importance of experience and would they not both work together most effectively? You will admit that there is nothing essential in the work of psychiatry which could oppose psycho-analytic researches. It is therefore the psychiatrists who oppose it, and not psychiatry itself. Psycho-analysis stands to psychiatry more or less as histology does to anatomy; in one, the outer forms of organs are studied, in the other, the construction of these out of the tissues and constituent elements. It is not easy to conceive of any contradiction between these two fields of study, in which the work of the one is continued in the other. You know that nowadays anatomy is the basis of the scientific study of medicine; but time was when dissecting human corpses in order to discover the internal structure of the body was as much a matter for severe prohibition as practising psycho-analysis in order to discover the internal workings of the human mind seems today to be a matter for condemnation. And, presumably at a not too distant date, we shall have perceived that there can be no psychiatry which is scientifically radical without a thorough knowledge of the deep-seated unconscious processes in mental life.

There may be some of you who perhaps are friendly enough towards psycho-analysis, often attacked as it is, to wish that it would justify itself in another direction also, that is, therapeutically. You know that psychiatric therapy has hitherto been unable to influence delusions. Can psycho-analysis do so perhaps, by reason of its insight into the mechanism of these symptoms? No, I have to tell you that it cannot; for the present, at any rate, it is just as powerless as any other therapy to heal these sufferers. It is true that we can understand what has happened to the patient; but we have no means by which we can make him understand it himself. You have heard that I could not continue the analysis of this delusion beyond the first preliminaries. Would you then maintain that analysis of such cases is undesirable because it remains fruitless? I do not think so. It is our right, yes, and our duty, to pursue

our researches without respect to the immediate gain effected. The day will come, where and when we know not, when every little piece of knowledge will be converted into power, and into therapeutic power. Even if psycho-analysis showed itself as unsuccessful with all other forms of nervous and mental diseases as with delusions, it would still remain justified as an irreplaceable instrument of scientific research. It is true that we should not be in a position to practise it; the human material on which we learn lives, and has its own will, and must have its own motives in order to participate in the work; and it would then refuse to do so. I will therefore close my lecture for today by telling you that there are large groups of nervous disturbances for which this conversion of our own advance in knowledge into therapeutic power has actually been carried out; and that with these diseases, otherwise so refractory, our measures yield under certain conditions, results which give place to none in the domain of medical therapy.

## SEVENTEENTH LECTURE

### THE MEANING OF SYMPTOMS

IN THE last lecture I explained to you that clinical psychiatry troubles itself little about the actual form of the individual symptom or the content of it; but that psycho-analysis has made this its starting-point, and has ascertained that the symptom itself has a meaning and is connected with experiences in the life of the patient. The meaning of neurotic symptoms was first discovered by J. Breuer in the study and successful cure of a case of hysteria (1880-82), which has since then become famous. It is true that P. Janet independently reached the same result; in fact, priority in publication must be granted to the French investigator, for Breuer did not publish his observations until more than a decade later (1893-95), during the period of our work together. Incidentally, it is of no great importance to us who made the discovery, for you know that every discovery is made more than once, and none is made all at once, nor is success meted out according to deserts. America is not called after Columbus. Before Breuer and Janet, the great psychiatrist Leuret expressed the opinion that even the delusions of the insane would prove to have some meaning, if only we knew how to translate them. I confess that for a long time I was willing to accord Janet very high recognition for his explanation of neurotic symp-

toms, because he regarded them as expressions of "*idées inconscientes*" possessing the patient's mind. Since then, however, Janet has taken up an attitude of undue reserve, as if he meant to imply that the unconscious had been nothing more to him than a manner of speaking, a makeshift, *une façon de parler*, and that he had nothing "real" in mind. Since then I have not understood Janet's views, but I believe that he has gratuitously deprived himself of great credit.

Neurotic symptoms then, just like errors and dreams, have their meaning and, like these, are related to the life of the person in whom they appear. This is an important matter which I should like to demonstrate to you by some examples. I can merely assert, I cannot prove, that it is so in every case; anyone observing for himself will be convinced of it. For certain reasons though, I shall not take these examples from cases of hysteria, but from another very remarkable form of neurosis, closely allied in origin to the latter, about which I must say a few preliminary words. This, which we call the *obsessional neurosis*, is not so popular as the widely known *hysteria*; it is, if I may so express myself, not so noisily ostentatious, behaves more as if it were a private affair of the patient's, dispenses almost entirely with bodily manifestations and creates all its symptoms in the mental sphere. The obsessional neurosis and hysteria are the two forms of neurotic disease upon the study of which psycho analysis was first built up, and in the treatment of which also our therapy celebrates its triumphs. In the obsessional neurosis, however, that mysterious leap from the mental to the physical is absent, and it has really become more intimately comprehensible and transparent to us through psycho analytic research than hysteria; we have come to understand that it displays far more markedly certain extreme features of the neurotic constitution.

The obsessional neurosis<sup>1</sup> takes this form: the patient's mind is occupied with thoughts that do not really interest him, he feels impulses which seem alien to him, and he is impelled to perform actions which not only afford him no pleasure but from which he is powerless to desist. The thoughts (obsessions) may be meaningless in themselves or only of no interest to the patient; they are often absolutely silly; in every case they are the starting-point of a strained concentration of thought which

exhausts the patient and to which he yields most unwillingly. Against his will he has to worry and speculate as if it were a matter of life or death to him. The impulses which he perceives within him may seem to be of an equally childish and meaningless character; mostly, however, they consist of something terrifying, such as temptations to commit serious crimes, so that the patient not only repudiates them as alien, but flees from them in horror, and guards himself by prohibitions, precautions, and restrictions against the possibility of carrying them out. As a matter of fact he never, literally not even once, carries these impulses into effect; flight and precautions invariably win. What he does really commit are very harmless, certainly trivial acts—what are termed the obsessive actions—which are mostly repetitions and ceremonial elaborations of ordinary every-day performances, making these common necessary actions—going to bed, washing, dressing, going for walks, etc.—into highly laborious tasks of almost insuperable difficulty. The morbid ideas, impulses, and actions are not by any means combined in the same proportions in individual types and cases of the obsessional neurosis; on the contrary, the rule is that one or another of these manifestations dominates the picture and gives the disease its name; but what is common to all forms of it is unmistakable enough.

This is a mad disease, surely. I don't think the wildest psychiatric phantasy could have invented anything like it, and if we did not see it every day with our own eyes we could hardly bring ourselves to believe in it. Now do not imagine that you can do anything for such a patient by advising him to distract himself, to pay no attention to these silly ideas, and do something sensible instead of his nonsensical practises. This is what he would like himself; for he is perfectly aware of his condition, he shares your opinion about his obsessional symptoms, he even volunteers it quite readily. Only he simply cannot help himself; the actions performed in an obsessional condition are supported by a kind of energy which probably has no counterpart in normal mental life. Only one thing is open to him—he can displace and he can exchange; instead of one silly idea he can adopt another of a slightly milder character, from one precaution or prohibition he can proceed to another, instead of one ceremonial rite he can perform another. He can displace his sense of compulsion, but he cannot dispel it. This capacity for displacing all the symptoms,

<sup>1</sup> Sometimes called in English *compulsion-neurosis*.  
—Tr.

involving radical alteration of their original forms, is a main characteristic of the disease; it is, moreover, striking that in this condition the *opposite values* (*polarities*) pervading mental life appear to be exceptionally sharply differentiated. In addition to compulsions of both positive and negative character, doubt appears in the intellectual sphere, gradually spreading until it gnaws even at what is usually held to be certain. All these things combine to bring about an ever-increasing indecisiveness, loss of energy, and curtailment of freedom; and that although the obsessional neurotic is originally always a person of a very energetic disposition, often highly opinionated, and as a rule intellectually gifted above the average. He has usually attained to an agreeably high standard of ethical development, is over-conscientious, and more than usually correct. You may imagine that it is a sufficiently arduous task to find one's bearings in this maze of contradictory character-traits and morbid manifestations. At the moment our aim is merely to interpret some symptoms of this disease.

Perhaps in view of our previous discussions you would like to know what present-day psychiatry has to offer concerning the obsessional neurosis; it is but a miserable contribution, however. Psychiatry has given names to the various compulsions, and has nothing more to say about them. It asserts instead that persons exhibiting these symptoms are *degenerate*. That is not much satisfaction to us; it is no more than an estimate of their value, a condemnation instead of an explanation. We are intended, I suppose, to conclude that deterioration from type would naturally produce all kinds of oddities in people. Now, we do believe that people who develop such symptoms must be somewhat different in type from other human beings; but we should like to know whether they are more *degenerate* than other nervous patients, than hysterical or insane people. The characterization is clearly again much too general. One may even doubt whether it is justified at all when one learns that such symptoms occur in men and women of exceptional ability who have left their mark on their generation. Thanks to their own discretion and the untruthfulness of biographers we usually learn very little of an intimate nature about our exemplary great men; but it does happen occasionally that one of them is a fanatic about truth like Emile Zola,<sup>1</sup> and then we hear of the

many extraordinary obsessive habits from which he suffered throughout life.

Psychiatry has got out of this difficulty by dubbing these people "*dégénérés supérieurs*." Very well; but psycho-analysis has shown that these extraordinary obsessional symptoms can be removed permanently, like the symptoms of other diseases, and as in other people who are not degenerate. I myself have frequently succeeded in doing so.

I shall only give you two examples of analysis of obsessional symptoms; one is an old one, but I have never found a better; and one is a recent one. I shall limit myself to these two because an account of this kind must be very explicit and go into great detail.

A lady of nearly thirty years of age suffered from very severe obsessional symptoms. I might perhaps have been able to help her if my work had not been destroyed by the caprice of fate—perhaps I shall tell you about it later. In the course of a day she would perform the following peculiar obsessive act, among others, several times over. She would run out of her room into the adjoining one, there take up a certain position at the table in the center of the room, ring for her maid, give her a trivial order or send her away without, and then run back again. There was certainly nothing very dreadful about this, but it might well arouse curiosity. The explanation presented itself in the simplest and most unexceptionable manner, without any assistance on the part of the analyst. I cannot imagine how I could even have suspected the meaning of this obsession or could possibly have suggested an interpretation for it. Every time I had asked the patient, "Why do you do this? What is the meaning of it?" she had answered, "I don't know." But one day, after I had succeeded in overcoming a great hesitation on her part, involving a matter of principle, she suddenly did know, for she related the history of the obsessive act. More than ten years previously she had married a man very much older than herself, who had proved impotent on the wedding-night. Innumerable times on that night he had run out of his room into hers in order to make the attempt, but had failed every time. In the morning he had said angrily: "It's enough to disgrace one in the eyes of the maid who does the beds," and seizing a bottle of red ink which happened to be at hand he poured it on the sheet, but not exactly in the place where such a mark might have been. At first I did not understand what this recollec-

<sup>1</sup> E. Toulouse, *Émile Zola: Enquête medico-psychologique* (Paris, 1896).

tion could have to do with the obsessive act in question; for I could see no similarity between the two situations, except in the running from one room into the other, and perhaps also in the appearance of the servant on the scene. The patient then led me to the table in the adjoining room, where I found a great mark on the table-cover. She explained further that she stood by the table in such a way that when the maid came in she could not miss seeing this mark. After this, there could no longer be any doubt about the connection between the current obsessive act and the scene of the wedding-night, though there was still a great deal to learn about it.

It was clear, first of all, that the patient identified herself with her husband; in imitating his running from one room into another she acted his part. To keep up the similarity we must assume that she has substituted the table and table-cover for the bed and sheet. This might seem too arbitrary; but then we have not studied dream-symbolism in vain. In dreams a table is very often found to represent a bed. *Bed and board* together mean marriage, so that the one easily stands for the other.

All this would be proof enough that the obsessive act is full of meaning; it *seems* to be a representation, a repetition of that all-important scene. But we are not bound to stop at this semblance; if we investigate more closely the relation between the two situations we shall probably find out something more, the purpose of the obsessive act. The kernel of it evidently lies in the calling of the maid, to whom she displays the mark, in contrast to her husband's words: "It's enough to disgrace one before the servant." In this way he, whose part she is playing, is *not* ashamed before the servant, the stain is where it ought to be. We see therefore that she has not simply repeated the scene, she has continued it and corrected it, transformed it into what it ought to have been. This implies something else, too, a correction of the circumstance which made that night so distressing, and which made the red ink necessary: namely, the husband's impotence. The obsessive act thus says: "No, it is not true, he was not disgraced before the servant, he was not impotent." As in a dream she represents this wish as fulfilled, in a current obsessive act, which serves the purpose of restoring her husband's credit after that unfortunate incident.

Everything else which I could tell you about this lady fits in with this, or, more correctly stated, everything else that we know about her

points to this interpretation of the obsessive act, in itself so incomprehensible. She had been separated from her husband for years and was trying to make up her mind to divorce him legally. But there would have been no prospect of being free from him in her mind; she forced herself to be true to him. She withdrew from the world and from everyone so that she might not be tempted, and in her phantasies she excused and idealized him. The deepest secret of her illness was that it enabled her to shield him from malicious gossip, to justify her separation from him, and to make a comfortable existence apart from her possible for him. The analysis of a harmless obsessive act thus leads straight to the inmost core of the patient's disease, and at the same time betrays a great deal of the secret of the obsessional neurosis in general. I am quite willing that you should spend some time over this example, for it unites conditions which cannot reasonably be expected in all cases. The interpretation of the symptom was discovered by the patient herself in a flash, without guidance or interference from the analyst, and it had arisen in connection with an event which did not belong, as it commonly does, to a forgotten period in childhood, but which had occurred in the patient's adult life and was clear in her memory. All those objections which critics habitually raise against our interpretations of symptoms are quite out of place here. To be sure, we cannot always be so fortunate.

And one thing more! Has it not struck you that this innocent obsessive act leads directly to this lady's most private affairs? A woman can hardly have anything more intimate to relate than the story of her wedding-night; and is it by chance and without special significance that we are led straight to the innermost secrets of her sexual life? It might certainly be due to the choice I made of this example. Let us not decide this point too quickly; but let us turn to the second example, which is of a totally different nature, and belongs to a very common type, that of rituals preparatory to sleep.

A well-grown clever girl of 19, the only child of her parents, superior to them in education and intellectual activity, was a wild, high-spirited child, but of late years had become very nervous without any apparent cause. She was very irritable, particularly with her mother, was discontented and depressed, inclined to indecision and doubt, finally confessing that she could no longer walk alone through squares and wide streets. We will not go very closely into her complicated condition, which requires at

least two diagnoses: agoraphobia and obsessional neurosis; but will turn our attention to the ritual elaborated by this young girl preparatory to going to bed, as a result of which she caused her parents great distress. In a certain sense, every normal person may be said to carry out a ritual before going to sleep, or at least, he requires certain conditions without which he is hindered in going to sleep; the transition from waking life to sleep has been made into a regular formula which is repeated every night in the same manner. But everything that a healthy person requires as a condition of sleep can be rationally explained, and if the external circumstances make any alteration necessary he adapts himself easily to it without waste of time. The morbid ritual on the other hand is inexorable, it will be maintained at the greatest sacrifices; it is disguised, too, under rational motives and appears superficially to differ from the normal only in a certain exaggerated carefulness of execution. On a closer examination, however, it is clear that the disguise is insufficient, that the ritual includes observances which go far beyond what reason can justify and even some which directly contravene this. As the motive of her nightly precautions, our patient declares that she must have silence at night and must exclude all possibility of noise. She does two things for this purpose; she stops the large clock in her room and removes all other clocks out of the room, including even the tiny wrist-watch on her bed-table. Flower-pots and vases are placed carefully together on the writing-table, so that they cannot fall down in the night and break, and so disturb her sleep. She knows that these precautions have only an illusory justification in the demand for quiet; the ticking of the little watch could not be heard, even if it lay on the table by the bed; and we all know that the regular ticking of a pendulum-clock never disturbs sleep, but is more likely to induce it. She also admits that her fear that the flower-pots and vases, if left in their places at night, might fall down of themselves and break is utterly improbable. For some other practices in her ritual this insistence upon silence as a motive is dropped; indeed, by ordaining that the door between her bedroom and that of her parents shall remain half-open (a condition which she ensures by placing various objects in the doorway) she seems, on the contrary, to open the way to sources of noise. The most important observances are concerned with the bed itself, however. The bolster at the head of the bed

must not touch the back of the wooden bedstead. The pillow must lie across the bolster exactly in a diagonal position and in no other; she then places her head exactly in the middle of this diamond, lengthways. The eiderdown must be shaken before she puts it over her, so that all the feathers sink to the foot-end; she never fails, however, to press this out and redistribute them all over it again.

I will pass over other trivial details of her ritual; they would teach us nothing new and lead us too far from our purpose. Do not suppose, though, that all this is carried out with perfect smoothness. Everything is accompanied by the anxiety that it has not all been done properly; it must be tested and repeated; her doubts fix first upon one, then another, of the precautions; and the result is that one or two hours elapse before the girl herself can sleep, or lets the intimidated parents sleep.

The analysis of these torments did not proceed so simply as that of the former patient's obsessive act. I had to offer hints and suggestions of its interpretation which were invariably received by her with a positive denial or with scornful doubt. After this first reaction of rejection, however, there followed a period in which she herself took up the possibilities suggested to her, noted the associations they aroused, produced memories, and established connections until she herself had accepted all the interpretations in working them out for herself. In proportion as she did this she began to relax the performance of her obsessive precautions and before the end of the treatment she had given up the whole ritual. I must also tell you that analytic work, as we conduct it nowadays, definitely excludes any uninterrupted concentration on a single symptom until its meaning becomes fully clear. It is necessary, on the contrary, to abandon a given theme again and again, in the assurance that one will come upon it anew in another context. The interpretation of the symptom, which I am now going to tell you, is therefore a synthesis of the results which, amid the interruptions of work on other points, took weeks and months to procure.

The patient gradually learnt to understand that she banished clocks and watches from her room at night because they were symbols of the female genitals. Clocks, which we know may have other symbolic meanings beside this, acquire this significance of a genital organ by their relation to periodical processes and regular intervals. A woman may be heard to boast

that menstruation occurs in her as regularly as clockwork. Now this patient's special fear was that the ticking of the clocks would disturb her during sleep. The ticking of a clock is comparable to the throbbing of the clitoris in sexual excitation. This sensation, which was distressing to her, had actually on several occasions wakened her from sleep; and now her fear of an erection of the clitoris expressed itself by the imposition of a rule to remove all going clocks and watches far away from her during the night. Flower-pots and vases are, like all receptacles, also symbols of the female genitals. Precautions to prevent them from falling and breaking during the night are therefore not lacking in meaning. We know the very widespread custom of breaking a vessel or a plate on the occasion of a betrothal; everyone present possesses himself of a fragment in symbolic acceptance of the fact that he may no longer put forward any claim to the bride, presumably a custom which arose with monogamy. The patient also contributed a recollection and several associations to this part of her ritual. Once as a child she had fallen while carrying a glass or porcelain vessel, and had cut her finger which had bled badly. As she grew up and learnt the facts about sexual intercourse, she developed the apprehension that on her wedding-night she would not bleed and so would prove not to be a virgin. Her precautions against the vases breaking signified a rejection of the whole complex concerned with virginity and with the question of bleeding during the first act of intercourse; a rejection of the anxiety both that she would bleed and that she would not bleed. These precautions were in fact only remotely connected with the prevention of noise.

One day she divined the central idea of her ritual when she suddenly understood her rule not to let the bolster touch the back of the bed. The bolster had always seemed a woman to her, she said, and the upright back of the bedstead a man. She wished therefore, by a magic ceremony, as it were, to keep man and woman apart; that is to say, to separate the parents and prevent intercourse from occurring. Years before the institution of her ritual, she had attempted to achieve this end by a more direct method. She had simulated fear, or had exploited a tendency to fear, so that the door between her bedroom and that of her parents should not be closed. This regulation was still actually included in her present ritual; in this way she managed to make it possible to overhear her parents; a proceeding which at one

time had caused her months of sleeplessness. Not content with disturbing her parents in this way, she at that time even succeeded occasionally in sleeping between the father and mother in their bed. *Bolster* and *bedstead* were then really prevented from coming together. As she finally grew too big to be comfortable in the same bed with the parents, she achieved the same thing by consciously simulating fear and getting her mother to change places with her and to give up to her, her place by the father. This incident was undoubtedly the starting-point of phantasies, the effect of which was evident in the ritual.

If the bolster was a woman, then the shaking of the eiderdown till all the feathers were at the bottom, making a protuberance there, also had a meaning. It meant impregnating a woman; she did not neglect, though, to obliterate the pregnancy again, for she had for years been terrified that intercourse between her parents might result in another child and present her with a rival. On the other hand, if the larger bolster meant the mother then the small pillow could only represent the daughter. Why had this pillow to be placed diamond-wise upon the bolster and her head be laid exactly in its middle lengthways? She was easily reminded that a diamond is repeatedly used in drawings on walls to signify the open female genitals. The part of the man (the father) she thus played herself and replaced the male organ by her own head. (Cf. Symbolism of beheading for castration.)

Horrible thoughts, you will say, to run in the mind of a virgin girl. I admit that; but do not forget that I have not invented these ideas, only exposed them. A ritual of this kind before sleep is also peculiar enough, and you cannot deny the correspondence, revealed by the interpretation, between the ceremonies and the phantasies. It is more important to me, however, that you should notice that the ritual was the outcome, not of one single phantasy, but of several together which of course must have had a nodal point somewhere. Note, too, that the details of the ritual reflect the sexual wishes both positively and negatively, and serve in part as expressions of them, in part as defences against them.

It would be possible to obtain much more out of the analysis of this ritual by bringing it into its place in connection with the patient's other symptoms. But that is not our purpose at the moment. You must be content with a reference to an erotic attachment to the father,

originating very early in childhood, which had enslaved this girl. It was perhaps for this reason that she was so unfriendly towards her mother. Also we cannot overlook the fact that the analysis of this symptom has again led to the patient's sexual life. The more insight we gain into the meaning and purpose of neurotic symptoms, the less surprising will this seem.

From two selected examples I have now shown you that neurotic symptoms have meaning, like errors and like dreams, and that they are closely connected with the events of the patient's life. Can I expect you to believe this exceptionally significant statement on the strength of two examples? No. But can you expect me to go on quoting examples to you until you declare yourselves convinced? Again, no; for in view of the exhaustive treatment given to each individual case I should have to devote five hours a week for a whole term to the consideration of this one point in the theory of the neuroses. I will content myself therefore with the samples given, as evidence of my statement; and will refer you for more to the literature on the subject, to the classical interpretation of symptoms in Breuer's first case (hysteria), to the striking elucidations of very obscure symptoms in dementia praecox, so-called, made by C. G. Jung at a time when this investigator was a mere psycho-analyst and did not yet aspire to be a prophet, and to all the subsequent contributions with which our periodicals have been filled since then. Precisely this type of investigation is plentiful. Analysis, interpretation, and translation of neurotic symptoms has proved so attractive to psycho-analysts that in comparison they have temporarily neglected the other problems of the neuroses.

Any one of you who makes the necessary effort to look up this question will certainly be strongly impressed by the wealth of evidential material. But he will also meet with a difficulty. The meaning of a symptom lies, as we have seen, in its connection with the life of the patient. The more individually the symptom has been formed, the more clearly may we expect to establish this connection. Then the task resolves itself specifically into a discovery, for every nonsensical idea and every useless action, of the past situation in which the idea was justified and the action served a useful purpose. The obsessive act of the patient who ran to the table and rang for the maid is a perfect model of this kind of symptom. But symptoms of quite a different type are very frequently seen. They are what we call *typical* symptoms of a

disease, in each case they are practically identical, the individual differences in them vanish or at least fade away, so that it is difficult to connect them with the patient's life or to relate them to special situations in his past. Let us consider the obsessional neurosis again. The second patient's ceremonies preparatory to sleep are in many ways quite typical, although showing enough individual features as well to make an "historical" interpretation, so to speak, possible. But all obsessional patients are given to repetitions, to isolating certain of their actions and to rhythmic performances. Most of them wash too much. Those patients who suffer from agoraphobia (topophobia, fear of space), no longer reckoned as an obsessional neurosis but now classified as anxiety-hysteria, reproduce the same features of the pathological picture often with fatiguing monotony. They fear enclosed spaces, wide, open squares, long stretches of road, and avenues; they feel protected if accompanied, or if a vehicle drives behind them, and so on. Nevertheless, on this groundwork of similarity the various patients construct individual conditions of their own, moods, one might call them, which directly contrast with other cases. One fears narrow streets only, another wide streets only, one can walk only when few people are about, others only when surrounded with people. Similarly in hysteria, beside the wealth of individual features there are always plenty of common typical symptoms which appear to resist an easy interpretation on historical lines. Do not let us forget that it is these typical symptoms which enable us to take our bearings in forming a diagnosis. Supposing we do trace back a typical symptom in a case of hysteria to an experience or to a chain of similar experiences (for instance, an hysterical vomiting to a series of impressions of a disgusting nature), it will be confusing to discover in another case of vomiting an entirely dissimilar series of apparently causative experiences. It almost looks as though hysterical patients must vomit, for some unknown reason, and as though the historical factors revealed by analysis were but pretexts, seized upon by an inner necessity, when opportunity offered, to serve its purpose.

This brings us to the discouraging conclusion that, although individual forms of neurotic symptoms can certainly be satisfactorily explained by their relation to the patient's experiences, yet our science fails us for the far more frequent typical symptoms in the same cases. In addition to this, I have not nearly

explained to you all the difficulties that arise during a resolute pursuit of the historical meaning of a symptom. Nor shall I do so; for although my intention is to conceal nothing from you and to gloss over nothing, I do not need to confuse you and stupefy you at the outset of our studies together. It is true that our understanding of symptom-interpretation has only just begun, but we will hold fast to the knowledge gained and proceed to overcome step by step the difficulties of the unknown. I will try to cheer you with the thought that it is hardly possible to presume a fundamental difference between the one kind of symptom and the other. If the individual form of symptom is so unmistakably connected with the patient's experiences, it is possible that the typical symptom relates to an experience which is itself typical and common to all humanity. Other regularly recurring features of a neurosis, such as the repetition and doubt of the obsessional neurosis, may be universal reactions which the patient is compelled to exaggerate by the nature of the morbid change. In short, there is no reason to give up hastily in despair; let us see what more we can find out.

There is a very similar difficulty met with in the theory of dreams, one which I could not deal with in the course of our previous discussions of dreams. The manifest content of dreams is multifarious and highly differentiated individually, and we have shown exhaustively what can be obtained by analysis from this content. But there are also dreams which may in the same way be called *typical* and occur in everybody, dreams with an identical content, which present the same difficulties to analysis. These are the dreams of falling, flying, floating, swimming, of being hindered, of being naked, and certain other anxiety-dreams; which yield first this, then that, interpretation, according to the person concerned, without any explanation of their monotonous and typical recurrence. But we notice that in these dreams also the common groundwork is embroidered with additions of an individually varying character. Most probably they too will prove to fit in with other knowledge about the dream-life, gained from a study of other kinds of dreams—not by any forcible twist, but by a gradual widening of our comprehension of these things.

## EIGHTEENTH LECTURE

### FIXATION UPON TRAUMAS: THE UNCONSCIOUS

I SAID last time that we would take, as a starting-point for further work, the knowledge we

have gained already, and not the doubts which it has roused in us. We have not yet even begun to discuss two of the most interesting conclusions arising from the analysis of the two examples.

First: both the patients give the impression that they are *fixed* to a particular point in their past, that they do not know how to release themselves from it, and are consequently alienated from both present and future. They are marooned in their illness, as it were; just as in former times people used to withdraw to the cloister to live out their unhappy fate there. In the case of the first patient, it was the marriage to the husband, which in reality had long ago come to an end, that had settled this doom upon her. Her symptoms enabled her to continue her relationship with him; we could perceive in them the voices which pleaded for him, excused him, exalted him, lamented his loss. Although she is young and could attract other men, she has seized upon every possible real and imaginary (magical) precaution that will preserve her fidelity to him. She will not meet strangers, she neglects her appearance; moreover, she cannot readily rise from any chair which she sits upon, and she refuses to sign her name and can give no presents, because no one must have anything which is hers.

With the second patient, the young girl, it is the erotic attachment to the father established in the years before puberty that plays this part in her life. She also has herself perceived that she cannot marry as long as she is so ill. We may suspect that she became so ill in order to be unable to marry and so to remain with her father.

We cannot avoid asking the question how, by what means and impelled by what motives, anyone can take up such an extraordinary and unprofitable attitude towards life. Provided, that is, that this attitude is a universal character of neurosis and is not a special peculiarity of these two patients. As a matter of fact, this is so; it is a universal trait common to every neurosis, and one of great practical significance. Breuer's first hysterical patient was *fixated*, in the same way, to the time when her father was seriously ill and she nursed him. In spite of her recovery, she has remained to some extent cut off from life since that time; for although she has remained healthy and active, she did not take up the normal career of a woman. In every one of our patients we learn through analysis that the symptoms and their effects have set

the sufferer back into some past period of his life. In the majority of cases it is actually a very early phase of the life history which has been thus selected, a period in childhood, even, absurd as it may sound, the period of existence as a suckling infant.

The closest analogy to this behaviour in our nervous patients is provided by the forms of illness recently made so common by the war—the so-called *traumatic neuroses*. Of course similar cases have occurred before the war, after railway accidents and other terrifying experiences involving danger to life. The traumatic neuroses are not fundamentally the same as those which occur spontaneously, which we investigate analytically and are accustomed to treat; neither have we been successful so far in correlating them with our views on other subjects; later on I hope to show you where this limitation lies. Yet there is a complete agreement between them on one point which may be emphasized. The traumatic neuroses demonstrate very clearly that a fixation to the moment of the traumatic occurrence lies at their root. These patients regularly produce the traumatic situation in their dreams; in cases showing attacks of an hysterical type in which analysis is possible, it appears that the attack constitutes a complete reproduction of this situation. It is as though these persons had not yet been able to deal adequately with the situation, as if this task were still actually before them unaccomplished. We take this attitude of theirs in all seriousness; it points the way to what we may call an *economic* conception of the mental processes. The term *traumatic* has actually no other meaning but this *economic* one. An experience which we call traumatic is one which within a very short space of time subjects the mind to such a very high increase of stimulation that assimilation or elaboration of it can no longer be effected by normal means, so that lasting disturbances must result in the distribution of the available energy in the mind.

This analogy tempts us also to classify as traumatic those experiences to which our nervous patients seem to be fixated. In this way we should be provided with a simple condition for a neurotic illness; it would be incomparable to a traumatic illness and would result from an incapacity to deal with an overpowering affective experience. Indeed, the first formula in which Breuer and I, in 1893-95, reduced our new observations to a theory was expressed very similarly. A case like that of the first

patient described, the young woman separated from her husband, fits very well into this description; she had not been able to get over the impracticability of her marriage and was still attached to her trauma. But the second case of the young girl who was tied to her father shows us at once that the formula is not comprehensive enough. On the one hand, an infantile adoration of her father by a little girl is such a common experience and so frequently grown out of that the term *traumatic* would lose all its meaning if applied to it; on the other hand, the history of the case shows that this first erotic fixation was gone through by the patient quite harmlessly at the time, to all appearances, and only several years later came to expression in the obsessional neurosis. So we see that there are complications ahead, a considerable variety and number of determining factors in neurosis; but we divine that the traumatic view will not necessarily be abandoned as false, and that it will fit in and have to be co-ordinated properly elsewhere.

Here again we must leave the path we have been following. At the moment it will take us no further, and we have much more to learn before we can find a satisfactory continuation of it. But before leaving the subject of fixation to traumas it should be noted that it is a phenomenon manifested extensively outside the neuroses; every neurosis contains such a fixation, but not every fixation leads to a neurosis, or is necessarily combined with a neurosis, or arises in the course of a neurosis. Grief is a prototype and perfect example of an affective fixation upon something that is past, and, like the neuroses, it also involves a state of complete alienation from the present and the future. But even the lay public distinguishes clearly between grief and neurosis. On the other hand, there are neuroses which may be described as morbid forms of grief.

It does also happen that persons may be brought to a complete standstill in life by a traumatic experience which has shaken the whole structure of their lives to the foundations, so that they give up all interest in the present and the future, and live permanently absorbed in their retrospections; but these unhappy persons do not necessarily become neurotic. Therefore this single feature must not be overestimated as a characteristic of neurosis, however invariable and significant it may be otherwise.

Now let us turn to the second conclusion to be drawn from our analyses; it is one upon

which we shall not need to impose any subsequent limitation. With the first patient we have heard of the senseless obsessive act she performed and of the intimate memories she recalled in connection with it; we also considered the relation between the two, and deduced the purpose of the obsessive act from its connection with the memory. But there is one factor which we have entirely neglected, and yet it is one which deserves our fullest attention. As long as the patient continued this performance she did not know that it was in any way connected with the previous experience; the connection between the two things was hidden; she could quite truly answer that she did not know what impulse led her to do it. Then it happened suddenly that, under the influence of the treatment, she found this connection and was able to tell it. But even then she knew nothing of the purpose she had in performing the action, the purpose that was to correct a painful event of the past and to raise the husband she loved in her own estimation. It took a long time and much effort for her to grasp, and admit to me, that such a motive as this alone could have been the driving force behind the obsessive act.

The connection with the scene on the morning after the unhappy bridal-night, and the patient's own tender feeling for her husband, together, make up what we have called the *meaning* of the obsessive act. But both sides of this meaning were hidden from her, she understood neither the *whence* nor the *whither* of her act, as long as she carried it on. Mental processes had been at work in her, therefore, of which the obsessive act was the effect; she was aware in a normal manner of their effect; but nothing of the mental antecedents of this effect had come to the knowledge of her consciousness. She was behaving exactly like a subject under hypnotism whom Bernheim had ordered to open an umbrella in the ward five minutes after he awoke, but who had no idea why he was doing it. This is the kind of occurrence we have in mind when we speak of the existence of *unconscious mental processes*; we may challenge anyone in the world to give a more correctly scientific explanation of this matter, and will then gladly withdraw our inference that unconscious mental processes exist. Until they do, however, we will adhere to this inference and, when anyone objects that in a scientific sense the unconscious has no reality, that it is a mere makeshift, *une façon de parler*, we must resign ourselves with a

shrug to rejecting his statement as incomprehensible. Something unreal, which can nevertheless produce something so real and palpable as an obsessive action!

In the second patient fundamentally the same thing is found. She has instituted a rule that the bolster must not touch the back of the bedstead, and she had to carry out this rule, but she does not know whence it comes, what it means, or to what it owes its strength. Whether she regards it indifferently, or struggles against it, or rages against it, or determines to overcome it, matters not; it will be followed. It must be followed; in vain she asks herself why. It is undeniable that these symptoms of the obsessional neurosis, these ideas and these impulses which arise no man knows where and which oppose such a powerful resistance against all the influences to which an otherwise normal mental life is susceptible, give the impression, even to the patients themselves, of being all powerful visitants from another world, immortal beings mingling in the whirlpool of mortal things. In these symptoms lies the clearest indication of a special sphere of mental activity cut off from all the rest. They show the way unmistakably to conviction on the question of the unconscious in the mind; and for that very reason clinical psychiatry, which only recognizes a psychology of consciousness, can do nothing with these symptoms except to stigmatize them as signs of a special kind of degeneration. Naturally, the obsessive idea and impulses are not themselves unconscious, any more that is the performance of the obsessive acts. They would not have become symptoms if they had not penetrated into consciousness. But the mental antecedents of them disclosed by analysis, the connections into which they fit after interpretation, are unconscious, at least until the time when we make the patient conscious of them by the work of the analysis.

Consider now, in addition, that the facts established in these two cases are confirmed in every symptom of every neurotic disease; that always and everywhere the meaning of the symptoms is unknown to the sufferer; that analysis invariably shows that these symptoms are derived from unconscious mental processes which can, however, under various favourable conditions, become conscious. You will then understand that we cannot dispense with the unconscious part of the mind in psycho-analysis, and that we are accustomed to deal with it as with something actual and tangible. Perhaps you will also be able to realize how unfitted all

those who only know the unconscious as a phrase, who have never analysed, never interpreted dreams, or translated neurotic symptoms into their meaning and intention, are to form an opinion on this matter. I will repeat the substance of it again in order to impress it upon you: The fact that it is possible to find meaning in neurotic symptoms by means of analytic interpretation is an irrefutable proof of the existence—or, if you prefer it, of the necessity for assuming the existence—of unconscious mental processes.

But that is not all. Thanks to a second discovery of Breuer's, for which he alone deserves credit and which seems to me even more far-reaching in its significance than the first, more still has been learnt about the relation between the unconscious and the symptoms of neurotics. Not merely is the meaning of the symptom invariably unconscious; there exists also a connection of a substitutive nature between the two; the existence of the symptom is only possible by reason of this unconscious activity. You will soon understand what I mean. With Breuer, I maintain the following: Every time we meet with a symptom we may conclude that definite unconscious activities which contain the meaning of the symptom are present in the patient's mind. Conversely, this meaning must be unconscious before a symptom can arise from it. Symptoms are not produced by conscious processes; as soon as the unconscious processes involved are made conscious the symptom must vanish. You will perceive at once that here is an opening for therapy, a way by which symptoms can be made to disappear. It was by this means that Breuer actually achieved the recovery of his patient, that is, freed her from her symptoms; he found a method of bringing into her consciousness the unconscious processes which contained the meaning of her symptoms and the symptoms vanished.

This discovery of Breuer's was not the result of any speculation but of a fortunate observation made possible by the co-operation of the patient. Now you must not rack your brains to try and understand this by seeking to compare it with something similar that is already familiar to you; but you must recognize in it a fundamentally new fact, by means of which much else becomes explicable. Allow me therefore to express it again to you in other words.

The symptom is formed as a substitute for something else which remains submerged. Certain mental processes would, under normal con-

ditions, develop until the person became aware of them consciously. This has not happened; and, instead, the symptom has arisen out of these processes which have been interrupted and interfered with in some way and have had to remain unconscious. Thus something in the nature of an exchange has occurred; if we can succeed in reversing this process by our therapy, we shall have performed our task of dispelling the symptom.

Breuer's discovery still remains the foundation of psycho-analytic therapy. The proposition that symptoms vanish when their unconscious antecedents have been made conscious has been borne out by all subsequent research; although the most extraordinary and unexpected complications are met with in attempting to carry this proposition out in practice. Our therapy does its work by transforming something unconscious into something conscious, and only succeeds in its work in so far as it is able to effect this transformation.

Now for a rapid digression, lest you should run the risk of imagining that this therapeutic effect is achieved too easily. According to the conclusions we have reached so far, neurosis would be the result of a kind of ignorance, a not-knowing of mental processes which should be known. This would approach very closely to the well-known Socratic doctrine according to which even vice is the result of ignorance. Now it happens in analysis that an experienced practitioner can usually surmise very easily what those feelings are which have remained unconscious in each individual patient. It should not therefore be a matter of great difficulty to cure the patient by imparting his knowledge to him and so relieving his ignorance. At least, one side of the unconscious meaning of the symptom would be easily dealt with in this way, although it is true that the other side of it, the connection between the symptom and the previous experiences in the patient's life, can hardly be divined thus; for the analyst does not know what the experiences have been, he has to wait till the patient remembers them and tells him. But one might find a substitute even for this in many cases. One might ask for information about his past life from the friends and relations; they are often in a position to know what events have been of a traumatic nature, perhaps they can even relate some of which the patient is ignorant because they took place at some very early period of childhood. By a combination of these two means it would seem that the pathogenic ignorance of the pa-

tients might be overcome in a short time without much trouble.

If only it were so! But we have made discoveries that we were quite unprepared for at first. There is knowing and knowing; they are not always the same thing. There are various kinds of knowing, which psychologically are not by any means of equal value. *Il y a fagots et fagots*,<sup>1</sup> as Molière says. Knowing on the part of the physician is not the same thing as knowing on the part of the patient and does not have the same effect. When the physician conveys his knowledge to the patient by telling him what he knows, it has effect. No, it would be incorrect to say that. It does not have the effect of dispersing the symptoms; but it has a different one, it sets the analysis in motion, and the first result of this is often an energetic denial. The patient has learned something that he did not know before—the meaning of his symptom—and yet he knows it as little as ever. Thus we discover that there is more than one kind of ignorance. It requires a considerable degree of insight and understanding of psychological matters in order to see in what the difference consists. But the proposition that symptoms vanish with the acquisition of knowledge of their meaning remains true, nevertheless. The necessary condition is that the knowledge must be founded upon an inner change in the patient which can only come about by a mental operation directed to that end. We are here confronted by problems which to us will soon develop into the *dynamics* of symptom-formation.

Now I must really stop and ask you whether all that I have been saying is not too obscure and complicated? Am I confusing you by so often qualifying and restricting, spinning out trains of thought and then letting them drop? I should be sorry if it were so. But I have a strong dislike of simplification at the expense of truth, I am not averse from giving you a full impression of the many-sidedness and intricacy of the subject, and also I believe that it does no harm to tell you more about each point than you can assimilate at the moment. I know that every listener and every reader arranges what is offered him as suits him in his own mind, shortens it, simplifies it, and extracts from it what he will retain. Within certain limits it is true that the more we begin with the more we shall have at the end. So let me hope that, in spite of the elaboration, you will have grasped the essential substance of my remarks concern-

ing the meaning of symptoms, the unconscious, and the connection between the two. You have probably understood also that our further efforts will proceed in two directions; first, towards discovering how people become ill, how they come to take up the characteristic neurotic attitude towards life, which is a clinical problem; and secondly, how they develop the morbid symptoms out of the conditions of a neurosis, which remains a problem of mental dynamics. The two problems must somewhere have a point of contact.

I shall not go further into this today; but as our time is not yet up I propose to draw your attention to another characteristic of our two analyses; namely, *the memory gaps or amnesias*, again a point which only later will appear in its full significance. You have heard that the task of the psycho-analytic treatment can be summed up in this formula: "Everything pathogenic in the unconscious must be transferred into consciousness." Now you will perhaps be astonished to hear that another formula may be substituted for that one: "All gaps in the patient's memory must be filled in, his amnesias removed." It amounts to the same thing; which means that an important connection is to be recognized between the development of the symptoms and the amnesias. If you consider the case of the first patient analysed you will, however, not find this view of amnesia justified; the patient had not forgotten the scene from which the obsessive act is derived; on the contrary, it was vivid in her memory, nor is there any other forgotten factor involved in the formation of her symptom. The situation is quite analogous, although less clear, in the second case, the girl with the obsessional ceremonies. She, too, had not really forgotten her behaviour in former years, the fact that she had insisted upon the open door between her parents' bedroom and her own, and that she had turned her mother out of her place in the parents' bed; she remembered it quite clearly, although with hesitation and unwillingness. What is remarkable about it is that the first patient, although she had carried out her obsessive act such a countless number of times, had not *once* been reminded of its similarity to the scene after the wedding-night, nor did this recollection ever occur to her when she was directly asked to search for the origin of her obsessive act. The same thing is true in the case of the girl, where not merely the ritual, but the situation which gave rise to it, was repeated identically every evening. In neither

<sup>1</sup> There are men and men.—ED.

case was there really an amnesia, a lapse of memory; but a connection, which should have existed intact and have led to the reproduction, the recollection, of the memory, had been broken. This kind of disturbance of memory suffices for the obsessional neurosis; in hysteria it is different. This latter neurosis is usually characterized by amnesias on a grand scale. As a rule the analysis of each single hysterical symptom leads to a whole chain of former impressions, which upon their return may be literally described as having been hitherto forgotten. This chain reaches, on the one hand, back to the earliest years of childhood, so that the hysterical amnesia is seen to be a direct continuation of the infantile amnesia which hides the earliest impressions of our mental life from all of us. On the other hand, we are astonished to find that the most recent experiences of the patient are liable to be forgotten also, and that in particular the provocations which induced the outbreak of the disease or aggravated it are at least partially obliterated, if not entirely wiped out, by amnesia. From the complete picture of any such recent recollection, important details have invariably disappeared or been replaced by falsifications. It happens again and again, almost invariably, that not until shortly before the completion of an analysis do certain recollections of recent experiences come to the surface, which had managed to be withheld throughout it and had left noticeable gaps in the context.

These derangements in the capacity to recall memories are, as I have said, characteristic of hysteria, in which disease it also happens even that states occur as symptoms (the hysterical attacks) without necessarily leaving a trace of recollection behind them. Since it is otherwise in the obsessional neurosis, you may infer that these amnesias are part of the psychological character of the hysterical change and are not a universal trait of neurosis in general. The importance of this difference will be diminished by the following consideration. Two things are combined to constitute the meaning of a symptom; its *whence* and its *whither* or *why*; that is, the impressions and experiences from which it sprang, and the purpose which it serves. The *whence* of a symptom is resolved into impressions which have been received from without, which were necessarily at one time conscious, and which may have become unconscious by being forgotten since that time. The *why* of the symptom, its tendency, is however always an endo-psychic process, which may

possibly have been conscious at first, but just as possibly may never have been conscious and may have remained in the unconscious from its inception. Therefore, it is not very important whether the amnesia has also infringed upon the *whence*, the impressions upon which the symptom is supported, as happens in hysteria; the *whither*, the tendency of the symptom, which may have been unconscious from the beginning, is what maintains the symptom's dependence upon the unconscious, in the obsessional neurosis no less strictly than in hysteria.

By thus emphasizing the unconscious in mental life we have called forth all the malevolence in humanity in opposition to psycho-analysis. Do not be astonished at this and do not suppose that this opposition relates to the obvious difficulty of conceiving the unconscious or to the relative inaccessibility of the evidence which supports its existence. I believe it has a deeper source. Humanity has in the course of time had to endure from the hands of science two great outrages upon its naïve self-love. The first was when it realized that our earth was not the centre of the universe, but only a tiny speck in a world system of a magnitude hardly conceivable; this is associated in our minds with the name of Copernicus, although Alexandrian doctrines taught something very similar. The second was when biological research robbed man of his peculiar privilege of having been specially created, and relegated him to a descent from the animal world, implying an ineradicable animal nature in him: this transvaluation has been accomplished in our own time upon the instigation of Charles Darwin, Wallace, and their predecessors, and not without the most violent opposition from their contemporaries. But man's craving for grandiosity is now suffering the third and most bitter blow from present-day psychological research which is endeavouring to prove to the *ego* of each one of us that he is not even master in his own house, but that he must remain content with the veriest scraps of information about what is going on unconsciously in his own mind. We psycho-analysts were neither the first nor the only ones to propose to mankind that they should look inward; but it appears to be our lot to advocate it most insistently and to support it by empirical evidence which touches every man closely. This is the kernel of the universal revolt against our science, of the total disregard of academic courtesy in dispute, and the liberation of opposition from all the constraints of impartial logic. And besides this, we

have been compelled to disturb the peace of the world in yet another way, as you will soon hear.

## NINETEENTH LECTURE

### RESISTANCE AND REPRESSION

WE now need more data before we can advance further in our understanding of the neuroses; two observations lie to hand for us. Both are very remarkable and at first were very surprising. You are of course prepared for both of them by the work we did last year.

First: when we undertake to cure a patient of his symptoms, he opposes against us a vigorous and tenacious *resistance* throughout the entire course of the treatment. This is such an extraordinary thing that we cannot expect much belief in it. It is best to say nothing about it to the patient's relations, for they invariably regard it as a pretext set up by us to excuse the length or the failure of the treatment. The patient, too, exhibits all the manifestations of this resistance without recognizing it as such, and it is a great step forward when we have brought him to realize this fact and to reckon with it. To think that the patient, whose symptoms cause him and those about him such suffering, who is willing to make such sacrifices in time, money, effort, and self-conquest in order to be freed from them—that he should, in the interests of his illness, resist the help offered him. How improbable this statement must sound! And yet it is so, and if the improbability is made a reproach against us we need only reply that it is not without its analogies; for a man who has rushed off to a dentist with a frightful toothache may very well fend him off when he takes his forceps to the decayed tooth.

The resistance shown by patients is highly varied and exceedingly subtle, often hard to recognize and protean in the manifold forms it takes; the analyst needs to be continually suspicious and on his guard against it. In psycho-analytic therapy we employ the technique which is already familiar to you through dream-interpretation: we require the patient to put himself into a condition of calm self-observation, without trying to think of anything, and then to communicate everything which he becomes inwardly aware of, feelings, thoughts, remembrances, in the order in which they arise in his mind. We expressly warn him against giving way to any kind of motive which would cause him to select from or to exclude any of the ideas (associations),

whether because they are too "disagreeable," or too "indiscreet" to be mentioned, or too "unimportant" or "irrelevant" or "nonsensical" to be worth saying. We impress upon him that he has only to attend to what is on the surface consciously in his mind, and to abandon all objections to whatever he finds, no matter what form they take; and we inform him that the success of the treatment, and, above all, its duration, will depend upon his conscientious adherence to this fundamental technical rule. We know from the technique of dream-interpretation that it is precisely those associations against which innumerable doubts and objections are raised that invariably contain the material leading to the discovery of the unconscious.

The first thing that happens as a result of instituting this technical rule is that it becomes the first point of attack for the resistance. The patient attempts to escape from it by every possible means. First he says nothing comes into his head, then that so much comes into his head that he can't grasp any of it. Then we observe with displeasure and astonishment that he is giving in to his critical objections, first to this, then to that; he betrays it by the long pauses which occur in his talk. At last he admits that he really cannot say something, he is ashamed to, and he lets this feeling get the better of his promise. Or else, he has thought of something but it concerns someone else and not himself, and is therefore to be made an exception to the rule. Or else, what he has just thought of is really too unimportant, too stupid and too absurd, I could never have meant that he should take account of such thoughts. So it goes on, with untold variations, to which one continually replies that telling everything really means telling everything.

One hardly ever meets with a patient who does not attempt to make a reservation in some department of his thoughts, in order to guard them against intrusion by the analysis. One patient, who in the ordinary way was remarkably intelligent, concealed a most intimate love-affair from me for weeks in this way; when accused of this violation of the sacred rule he defended himself with the argument that he considered this particular story his private affair. Naturally analytic treatment cannot countenance a right of sanctuary like this; one might as well try to allow an exception to be made in certain parts of a town like Vienna, and forbid that any arrests should be

made in the market-place or in the square by St. Stephen's church, and then attempt to take up a wanted man. Of course he would never be found anywhere but in those safe places. Once I decided to permit a man to make an exception of such a point; for a great deal depended on his recovering his capacity for work and he was bound by his oath as a civil servant not to communicate certain matters to any other person. He was content with the result, it is true, but I was not: I made up my mind never again to repeat the attempt under such conditions.

Obsessional patients are exceedingly clever at making the technical rule almost useless by bringing their over-conscientiousness and doubt to bear upon it. Patients with anxiety-hysteria sometimes succeed in reducing it to absurdity by only producing associations which are so far removed from what is wanted that they yield nothing for analysis. However, I do not intend to introduce you to these technical difficulties of the treatment. It is enough to know that finally, with resolution and perseverance, we do succeed in extracting from the patient a certain amount of obedience for the rules of the technique; and then the resistance takes another line altogether. It appears as intellectual opposition, employs arguments as weapons, and turns to its own use all the difficulties and improbabilities which normal but uninstructed reasoning finds in analytical doctrines. We then have to hear from the mouth of the individual patient all the criticisms and objections which thunder about us in chorus in scientific literature. What the critics outside shout at us is nothing new, therefore. It is indeed a storm in a teacup. Still, the patient can be argued with; he is very glad to get us to instruct him, teach him, defeat him, point out the literature to him so that he can learn more; he is perfectly ready to become a supporter of psycho-analysis on the condition that analysis shall spare him personally. We recognize resistance in this desire for knowledge, however; it is a digression from the particular task in hand and we refuse to allow it. In the obsessional neurosis the resistance makes use of special tactics which we are prepared for. It permits the analysis to proceed uninterruptedly along its course, so that more and more light is thrown upon the problems of the case, until we begin to wonder at last why these explanations have no practical effect and entail no corresponding improvement in the symptoms. Then we discover that the resistance has

fallen back upon the doubt characteristic of the obsessional neurosis and is holding us successfully at bay from this vantage-point. The patient has said to himself something of this kind: "This is all very pretty and very interesting. I should like to go on with it. I am sure it would do me a lot of good if it were true. But I don't believe it in the least, and as long as I don't believe it, it doesn't affect my illness." So it goes on for a long time, until at last this reservation itself is reached and then the decisive battle begins.

The intellectual resistances are not the worst; one can always get the better of them. But the patient knows how to set up resistances within the boundaries of analysis proper, and the defeat of these is one of the most difficult tasks of the technique. Instead of remembering certain of the feelings and states of mind of his previous life, he reproduces them, lives through again such of them as, by means of what is called the *transference*, may be made effective in opposition against the physician and the treatment. If the patient is a man, he usually takes this material from his relationship with his father, in whose place he has now put the physician; and in so doing he erects resistance out of his struggles to attain to personal independence and independence of judgment, out of his ambition, the earliest aim of which was to equal or to excel the father, out of his disinclination to take the burden of gratitude upon himself for the second time in his life. There are periods in which one feels that the patient's desire to put the analyst in the wrong, to make him feel his impotence, to triumph over him, has completely ousted the worthier desire to bring the illness to an end. Women have a genius for exploiting in the interests of resistance a tender erotically tinged transference to the analyst; when this attraction reaches a certain intensity all interest in the actual situation of treatment fades away, together with every obligation incurred upon undertaking it. The inevitable jealousy and the embitterment consequent upon the unavoidable rejection, however considerably it is handled, is bound to injure the personal relationship with the physician, and so to put out of action one of the most powerful propelling forces in the analysis.

Resistances of this kind must not be narrowly condemned. They contain so much of the most important material from the patient's past life and bring it back in so convincing a fashion that they come to be of the greatest

assistance to the analysis, if a skilful technique is employed correctly to turn them to the best use. What is noteworthy is that this material always serves at first as a resistance and comes forward in a guise which is inimical to the treatment. Again it may be said that they are character-traits, individual attitudes of the ego, which are thus mobilized to oppose the attempted alterations. One learns then how these character-traits have been developed in connection with the conditions of the neurosis and in reaction against its demands, and observes features in this character which would not otherwise have appeared, at least, not so clearly: that is, which may be designated latent. Also you must not carry away the impression that we look upon the appearance of these resistances as an unforeseen danger threatening our analytic influence. No, we know that these resistances are bound to appear; we are dissatisfied only if we cannot rouse them definitely enough and make the patient perceive them as such. Indeed, we understand at last that the overcoming of these resistances is the essential work of the analysis, that part of the work which alone assures us that we have achieved something for the patient.

Besides this, you must take into account that all accidental occurrences arising during the treatment are made use of by the patient to interfere with it, anything which could distract him or deter him from it, every hostile expression of opinion from anyone in his circle whom he can regard as an authority, any chance organic illness or one complicating the neurosis; indeed, he even converts every improvement in his condition into a motive for slackening his efforts. Then you will have obtained an approximate, though still incomplete, picture of the forms and the measures taken by the resistances which must be met and overcome in the course of every analysis. I have given such a detailed consideration to this point because I am about to inform you that our dynamic conception of the neuroses is founded upon this experience of ours of the resistances that neurotic patients set up against the cure of their symptoms. Breuer and I both originally practiced psycho-therapy by the hypnotic method. Breuer's first patient was treated throughout in a state of hypnotic suggestibility; at first I followed his example. I admit that at that time my work went forward more easily and agreeably and also took much less time: but the results were capricious and not permanent; therefore I finally gave up hypnotism.

And then I understood that no comprehension of the dynamics of these affections was possible as long as hypnosis was employed. In this condition the very existence of resistances is concealed from the physician's observation. Hypnosis drives back the resistances and frees a certain field for the work of the analysis, but dams them up at the boundaries of this field so that they are insurmountable; it is similar in effect to the doubt of the obsessional neurosis. Therefore I may say that true psycho-analysis only began when the help of hypnosis was discarded.

If it is a matter of such importance to establish these resistances then surely it would be wise to allow caution and doubt full play, in case we have been too ready with our assumption that they exist. Perhaps cases of neurosis may be found in which the associations really fail for other reasons, perhaps the arguments against our theories really deserve serious attention, and we may be wrong in so conveniently disposing of the patient's intellectual objections by stigmatizing them as resistance. Well, I can only assure you that our judgment in this matter has not been formed hastily; we have had opportunity to observe these critical patients both before the resistance comes to the surface and after it disappears. In the course of the treatment the resistance varies in intensity continually; it always increases as a new topic is approached, it is at its height during the work upon it, and dies down again when this theme has been dealt with. Unless certain technical errors have been committed, we never have to meet the full measure of resistance, of which any patient is capable, at once. Thus we could definitely ascertain that the same man would take up and then abandon his critical objections over and over again in the course of the analysis. Whenever we are on the point of bringing to his consciousness some piece of unconscious material which is particularly painful to him, then he is critical in the extreme; even though he may have previously understood and accepted a great deal, yet now all these gains seem to be obliterated; in his struggles to oppose at all costs he can behave just as though he were mentally deficient, a form of *emotional stupidity*. If he can be successfully helped to overcome this new resistance he regains his insight and comprehension. His critical faculty is not functioning independently, and therefore is not to be respected as if it were; it is merely a maid-of-all-work for his affective attitudes and is directed by his resistance. When he dis-

likes anything he can defend himself against it most ingeniously; but when anything suits his book he can be credulous enough. We are perhaps all much the same; a person being analysed shows this dependence of the intellect upon the affective life so clearly because in the analysis he is so hard pressed.

In what way can we now account for this fact observed, that the patient struggles so energetically against the relief of his symptoms and the restoration of his mental processes to normal functioning? We say that we have come upon the traces of powerful forces at work here opposing any change in the condition; they must be the same forces that originally induced the condition. In the formation of symptoms some process must have been gone through, which our experience in dispersing them makes us able to reconstruct. As we already know from Breuer's observations, it follows from the existence of a symptom that some mental process has not been carried through to an end in a normal manner so that it could become conscious; the symptom is a substitute for that which has not come through. Now we know where to place the forces which we suspect to be at work. A vehement effort must have been exercised to prevent the mental process in question from penetrating into consciousness and as a result it has remained unconscious; being unconscious it had the power to construct a symptom. The same vehement effort is again at work during analytic treatment, opposing the attempt to bring the unconscious into consciousness. This we perceive in the form of resistances. The pathogenic process which is demonstrated by the resistances we call **REPRESSION**.

It will now be necessary to make our conception of this process of *repression* more precise. It is the essential preliminary condition for the development of symptoms, but it is also something else, a thing to which we have no parallel. Let us take as a model an impulse, a mental process seeking to convert itself into action: we know that it can suffer rejection, by virtue of what we call *repudiation* or *condemnation*; whereupon the energy at its disposal is withdrawn, it becomes powerless, but it can continue to exist as a memory. The whole process of decision on the point takes place with the full cognizance of the ego. It is very different when we imagine the same impulse subject to *repression*: it would then retain its energy and no memory of it would be left behind; the process of repression, too, would

be accomplished without the cognizance of the ego. This comparison therefore brings us no nearer to the nature of repression.

I will expound to you those theoretical conceptions which alone have proved useful in giving greater definiteness to the term *repression*. For this purpose it is first necessary that we should proceed from the purely descriptive meaning of the word *unconscious* to its systematic meaning; that is, we resolve to think of the consciousness or unconsciousness of a mental process as merely one of its qualities and not necessarily definitive. Suppose that a process of this kind has remained unconscious, its being withheld from consciousness may be merely a sign of the fate it has undergone, not necessarily the fate itself. Let us suppose, in order to gain a more concrete notion of this fate, that every mental process—there is one exception, which I will go into later—first exists in an unconscious state or phase, and only develops out of this into a conscious phase, much as a photograph is first a negative and then becomes a picture through the printing of the positive. But not every negative is made into a positive, and it is just as little necessary that every unconscious mental process should convert itself into a conscious one. It may be best expressed as follows: Each single process belongs in the first place to the unconscious psychical system; from this system it can under certain conditions proceed further into the conscious system.

The crudest conception of these systems is the one we shall find most convenient, a spatial one. The unconscious system may therefore be compared to a large ante-room, in which the various mental excitations are crowding upon one another, like individual beings. Adjoining this is a second, smaller apartment, a sort of reception-room, in which consciousness resides. But on the threshold between the two there stands a personage with the office of door-keeper, who examines the various mental excitations, censors them, and denies them admittance to the reception-room when he disapproves of them. You will see at once that it does not make much difference whether the door-keeper turns any one impulse back at the threshold, or drives it out again once it has entered the reception-room; that is merely a matter of the degree of his vigilance and promptness in recognition. Now this metaphor may be employed to widen our terminology. The excitations in the unconscious, in the ante-chamber, are not visible to consciousness,

which is of course in the other room, so to begin with they remain unconscious. When they have pressed forward to the threshold and been turned back by the door-keeper, they are *incapable of becoming conscious*; we call them then *repressed*. But even those excitations which are allowed over the threshold do not necessarily become conscious; they can only become so if they succeed in attracting the eye of consciousness. This second chamber therefore may be suitably called the *preconscious system*. In this way the process of becoming conscious retains its purely descriptive sense. Being repressed, when applied to any single impulse, means being unable to pass out of the unconscious system because of the door-keeper's refusal of admittance into the preconscious. The door-keeper is what we have learnt to know as resistance in our attempts in analytic treatment to loosen the repressions.

Now I know very well that you will say that these conceptions are as crude as they are fantastic and not at all permissible in a scientific presentation. I know they are crude; further indeed, we even know that they are incorrect, and unless I am mistaken, we have something better ready as a substitute for them; whether you will then continue to think them so fantastic, I do not know. At the moment they are useful aids to understanding, like *Ampère's* manikin swimming in the electric current, and, in so far as they do assist comprehension, are not to be despised. Still, I should like to assure you that these crude hypotheses, the two chambers, the door-keeper on the threshold between the two, and consciousness as a spectator at the end of the second room, must indicate an extensive approximation to the actual reality. I should also like to hear you admit that our designations, unconscious, preconscious, and conscious, are less prejudicial and more easily defensible than some others which have been suggested or have come into use, e.g., sub-conscious, inter-conscious, co-conscious, etc.

If so, I should think it more significant if you then went on to point out that any such constitution of the mental apparatus as I have assumed in order to account for neurotic symptoms can only be of universal validity and must throw light on normal functioning. In this, of course, you are perfectly right. We cannot follow up this conclusion at the moment; but our interest in the psychology of symptom-development would certainly be

enormously increased if we could see any prospect of obtaining, by the study of pathological conditions, an insight into normal mental functioning, hitherto such a mystery.

Do you not recognize, moreover, what it is that supports these conceptions of the two systems and the relationship between them and consciousness? The door-keeper between the unconscious and the preconscious is nothing else than the *ensorship* to which we found the form of the manifest dream subjected. The residue of the day's experiences which we found to be the stimuli exciting the dream, was preconscious material which at night during sleep had been influenced by unconscious and repressed wishes and excitations; and had thus by association with them been able to form the latent dream, by means of their energy. Under the dominion of the unconscious system this material had been elaborated (worked over)—by condensation and displacement—in a way which in normal mental life, i.e., in the preconscious system, is unknown or admissible very rarely. This difference in their manner of functioning is what distinguishes the two systems for us; the relationship to consciousness, which is a permanent feature of the preconscious, indicates to which of the two systems any given process belongs. Neither is dreaming a pathological phenomenon; every healthy person may dream while asleep. Every inference concerning the constitution of the mental apparatus which comprises an understanding of both dreams and neurotic symptoms has an irrefutable claim to be regarded as applying also to normal mental life.

This is as much as we will say about repression for the present. Moreover, it is but a necessary preliminary condition, a prerequisite, of symptom-formation. We know that the symptom is a substitute for some other process which was held back by repression; but even given repression we have still a long way to go before we can obtain comprehension of this substitute-formation. There are other sides to the problem of repression itself which present questions to be answered: What kind of mental excitations suffer repression? What forces effect it? and from what motives? On one point only, so far, have we gained any knowledge relevant to these questions. While investigating the problem of resistance we learned that the forces behind it proceed from the ego, from character-traits, recognizable or latent: it is these forces therefore which have also effected the repression, or at least they

have taken a part in it. We know nothing more than this at present.

The second observation for which I prepared you will help us now. By means of analysis we can always discover the purpose behind the neurotic symptom. This is of course nothing new to you: I have already pointed it out in two cases of neurosis. But, to be sure, what do two cases signify? You have a right to demand two hundred cases, innumerable cases, in demonstration of it. But then, I cannot comply with that. So you must fall back on personal experience, or upon belief, which in this matter can rely upon the unanimous testimony of all psycho-analysts.

You will remember that in the two cases in which we submitted the symptoms to detailed investigation analysis led to the innermost secrets of the patient's sexual life. In the first case, moreover, the purpose or tendency of the symptom under examination was particularly evident; in the second case, it was perhaps to some extent veiled by another factor to be mentioned later. Well now, what we found in these two examples we should find in every case we submitted to analysis. Every time we should be led by analysis to the sexual experiences and desires of the patient, and every time we should have to affirm that the symptom served the same purpose. This purpose shows itself to be the gratification of sexual wishes; the symptoms serve the purpose of sexual gratification for the patient; they are a substitute for satisfactions which he does not obtain in reality.

Think of the obsessive act of our first patient. This woman has to do without the husband she loved so intensely; on account of his deficiencies and short-comings she could not share his life. She had to be faithful to him; she could not put anyone else in his place. Her obsessional symptom gives her what she so much desires; it exalts her husband, denies and corrects his deficiencies, above all, his impotence. This symptom is fundamentally a wish-fulfilment, in that respect exactly like a dream; it is, moreover, what a dream is not always, an erotic wish-fulfilment. In the case of the second patient you could see that her ritual aims at preventing intercourse between the parents or at hindering the procreation of another child; you have probably also divined that fundamentally it seeks to set her in her mother's place. It again, therefore, constitutes a removal of hindrances to sexual satisfaction and the fulfilment of the subject's own sexual

wishes. Of the complications referred to in the second case I shall speak shortly.

I wish to avoid making reservations later on about the universal applicability of these statements, and therefore I will ask you to notice that all I have just been saying about repression, symptom-formation and symptom-interpretation has been obtained from the study of three types of neurosis, and for the present is only applicable to these three types—namely, *anxiety-hysteria*, *conversion-hysteria*, and *the obsessional neurosis*. These three disorders, which we are accustomed to combine together in a group as the TRANSFERENCE NEUROSES, constitute the field open to psycho-analytic therapy. The other neuroses have been far less closely studied psycho-analytically; in one group of them the impossibility of therapeutic influence has no doubt been one reason for this neglect. You must not forget that psycho analysis is still a very young science, that much time and trouble are required for the study of it, and that not so very long ago there was only one man practising it: yet we are approaching from all directions to a nearer comprehension of these other conditions which are not transference neuroses. I hope I shall still be able to tell you of the developments that our hypotheses and conclusions have undergone in the course of adaptation to this new material, and to show you that these further studies have not yielded contradictions but have led to a higher degree of unification in our knowledge. Everything that has been said, then, applies only to the three transference neuroses and I will now add another piece of information which throws further light upon the significance of the symptoms. A comparative examination of the situation out of which the disease arose yields the following result, which may be reduced to a formula—namely, that these persons have fallen ill from the privation (frustration) which they suffer when reality withholds from them gratification of their sexual wishes. You will perceive how beautifully these two conclusions supplement one another. The symptoms are now explicable as substitute-gratifications for desires which are unsatisfied in life.

It is certainly possible to make all kinds of objections to the proposition that neurotic symptoms are substitutes for sexual gratifications. I will discuss two of them today. If any one of you has himself undertaken the analysis of a large number of neurotics, he will perhaps shake his head and say: "In certain cases this

is not at all applicable, in them the symptoms seem rather to contain the opposite purpose, of excluding or of discontinuing sexual gratification." I shall not dispute your interpretation. In psycho-analysis things are often a good deal more complicated than we could wish: if they had been simpler psycho-analysis would perhaps not have been required to bring them to light. Certain features of the ritual of our second patient are distinctly recognizable as being of this ascetic character, inimical to sexual satisfaction; e.g., her removing the clocks for the magic purpose of preventing erections at night, or her trying to prevent the falling and breaking of vessels, which amounts to a protection of her virginity. In other cases of ceremonials on going to bed which I have analysed this negative character was far more marked; the whole ritual could consist of defensive regulations against sexual recollections and temptations. But we have long ago learnt from psycho-analysis that opposites do not constitute a contradiction. We might extend our proposition and say that the purpose of the symptom is either a sexual gratification or a defence against it; in hysteria the positive, wish-fulfilling character predominates on the whole, and in the obsessional neurosis the negative ascetic character. The symptoms can serve the purpose both of sexual gratification and of its opposite so well because this double-sidedness, or *polarity*, has a most suitable foundation in one element of their mechanism which we have not yet had an opportunity to mention. They are in fact, as we shall see, the effects of *compromises* between two opposed tendencies, acting on one another; they represent both that which is repressed, and also that which has effected the repression and has co-operated in bringing them about. The representation of either one or another of these two factors may predominate in the symptom, but it happens very rarely that one of them is absent altogether. In hysteria a collaboration of the two tendencies in one symptom is usually achieved. In the obsessional neurosis the two parts are often distinct: the symptom is then a double one and consists of two successive actions which cancel each other.

It will not be so easy to dispose of a second difficulty. When you consider a whole series of symptom-interpretations your first opinion would probably be that the conception of a sexual substitute-gratification has to be stretched to its widest limits in order to include them. You will not neglect to point out that these

symptoms offer nothing real in the way of gratification, that often enough they are confined to re-animating a sensation, or to enacting a phantasy arising from some sexual complex. Further, that the ostensible sexual gratification is very often of an infantile and unworthy character, perhaps approximating to a masturbatory act, or is reminiscent of dirty habits which long ago in childhood had been forbidden and abandoned. And further still, you will express your astonishment that anyone should reckon among sexual gratifications those which can only be described as gratifications of cruel or horrible appetites, or which may be termed unnatural. Indeed, we shall come to no agreement on these latter points until we have submitted human sexuality to a thorough investigation and have thus established what we are justified in calling sexual.

## TWENTIETH LECTURE

### THE SEXUAL LIFE OF MAN

ONE would certainly think that there could be no doubt about what is to be understood by the term *sexual*. First and foremost, of course, it means the *improper*, that which must not be mentioned. I have been told a story about some pupils of a famous psychiatrist, who once endeavoured to convince their master that the symptoms of an hysteric are frequently representations of sexual things. With this object, they took him to the bedside of an hysterical woman whose attacks were unmistakable imitations of childbirth. He objected, however: "Well, there is nothing sexual about childbirth." To be sure, childbirth is not necessarily always improper.

I perceive that you don't approve of my joking about such serious matters. It is not altogether a joke, however. Seriously, it is not so easy to define what the term *sexual* includes. Everything connected with the difference between the two sexes is perhaps the only way of hitting the mark; but you will find that too general and indefinite. If you take the sexual act itself as the central point, you will perhaps declare *sexual* to mean everything which is concerned with obtaining pleasurable gratification from the body (and particularly the sexual organs) of the opposite sex; in the narrowest sense, everything which is directed to the union of the genital organs and the performance of the sexual act. In doing so, however, you come very near to reckoning the sexual and the improper as identical, and childbirth would really

have nothing to do with sex. If then you make the function of reproduction the kernel of sexuality you run the risk of excluding from it a whole host of things like masturbation, or even kissing, which are not directed towards reproduction, but which are nevertheless undoubtedly sexual. However, we have already found that attempts at definition always lead to difficulties; let us give up trying to do any better in this particular case. We may suspect that in the development of the concept *sexual* something has happened which has resulted in what H. Silberer has aptly called a *covering error*. On the whole, indeed, we know pretty well what is meant by sexual.

In the popular view, which is sufficient for all practical purposes in ordinary life, sexual is something which combines references to the difference between the sexes, to pleasurable excitement and gratification, to the reproductive function, and to the idea of impropriety and the necessity for concealment. But this is no longer sufficient for science. For painstaking researches (only possible, of course, in a spirit of self-command maintained by self-sacrifice) have revealed that classes of human beings exist whose sexual life deviates from the usual one in the most striking manner. One group among these *perverts* has, as it were, expunged the difference between the sexes from its scheme of life. In these people, only the same sex as their own can rouse sexual desire; the other sex (especially the genital organ of the other sex) has absolutely no sexual attraction for them, can even in extreme cases be an object of abhorrence to them. They have thus, of course, foregone all participation in the process of reproduction. Such persons are called *homosexuals* or *inverts*. Often, though not always, they are men and women who otherwise have reached an irreproachably high standard of mental growth and development, intellectually and ethically, and are only afflicted with this one fateful peculiarity. Through the mouths of their scientific spokesmen they lay claim to be a special variety of the human race, a *third sex*, as they call it, standing with equal rights alongside the other two. We may perhaps have an opportunity of critically examining these claims. They are not, of course, as they would gladly maintain, the *elect* of mankind; they contain in their ranks at least as many inferior and worthless individuals as are to be found among those differently constituted sexually.

These perverses do at least seek to achieve very much the same ends with the objects of

their desires as normal people do with theirs. But after them comes a long series of abnormal types, in whom the sexual activities become increasingly further removed from anything which appears attractive to a reasonable being. In their manifold variety and their strangeness these types may be compared to the grotesque monstrosities painted by P. Breughel to represent the temptation of St. Anthony, or to the long procession of effete gods and worshippers which G. Flaubert shows us passing before his pious penitent, and to nothing else. The chaotic assembly calls out for classification if it is not to bewilder us completely. We divide them into those in whom the *sexual object* has been altered, as with the homosexuals, and those in whom, first and foremost, the *sexual aim* has been altered. In the first group belong those who have dispensed with the mutual union of the genital organs and who have substituted for the genitals, in one of the partners in the act, another organ or part of the body (mouth or anus, in place of the vagina) making light of both the anatomical difficulties and the suppression of disgust involved. There follow others who, it is true, still retain the genital organs as object; not, however, by virtue of their sexual function, but on account of other functions in which they take part anatomically or by reason of their proximity. These people demonstrate that the excretory functions, which in the course of the child's upbringing are relegated to a limbo as indecent, remain capable of attracting the entire sexual interest. There are others who have given up altogether the genital organs as object; and, instead, have exalted some other part of the body to serve as the object of desire, a woman's breast, foot, or plait of hair. There are others yet to whom even a part of the body is meaningless, while a particle of clothing, a shoe or a piece of under-clothing, will gratify all their desires; these are the fetichists. Farther on in the scale come those who indeed demand the object as a whole: but whose requirements in regard to it take specific forms, of an extraordinary or horrible nature—even to the point of seeking it as a defenceless corpse and, urged on by their criminal obsessions, of making it one in order so to enjoy it. But enough of these horrors!

Foremost in the second group are those perverses whose sexual desires aim at the performance of an act which normally is but an introductory or preparatory one. They are those who seek gratification in looking and touching,

or in watching the other person's most intimate doings; or those who expose parts of their own bodies which should be concealed, in the vague expectation of being rewarded by a similar action on the part of the other. Then come the incomprehensible sadists, in whom all affectionate feeling strains towards the one goal of causing their object pain and torture, ranging in degree from mere indications of a tendency to humiliate the other up to the infliction of severe bodily injuries. Then, as though complementary to these, come the masochists whose only longing is to suffer, in real or in symbolic form, humiliations and tortures at the hands of the loved object. There are others yet, in whom several abnormal characteristics of this kind are combined and interwoven with one another. Finally, we learn that the persons belonging to each of these groups may be divided again: into those who seek their particular form of sexual satisfaction in reality and those who are satisfied merely to imagine it in their own minds, needing no real object at all but being able to substitute for it a creation of phantasy.

There is not the slightest possible doubt that these mad, extraordinary and horrible things do actually constitute the sexual activities of these people. Not merely do they themselves so regard them, recognizing their substitutive character; but we also have to acknowledge that they play the same part in their lives as normal sexual satisfaction plays in ours, exacting the same, often excessive, sacrifices. It is possible to trace out, both broadly and in great detail, where these abnormalities merge into the normal and where they diverge from it. Nor will it escape you that that quality of impropriety which adheres inevitably to a sexual activity is not absent from these forms of it: in most of them it is intensified to the point of odium.

Well, now, what attitude are we to take up to these unusual forms of sexual satisfaction? Indignation and expressions of our personal disgust, together with assurances that we do not share these appetites, will obviously not carry us very far. That is not the point at issue. After all, this is a field of phenomena like any other; attempts to turn away and flee from it, on the pretext that these are but rarities and curiosities, could easily be rebutted. On the contrary, the phenomena are common enough and widely distributed. But if it is objected that our views on the sexual life of mankind require no revision on this account, since these things are one and all aberrations and divagations of the sex-

ual instinct, a serious reply will be necessary. If we do not understand these morbid forms of sexuality and cannot relate them to what is normal in sexual life, then neither can we understand normal sexuality. It remains, in short, our undeniable duty to account satisfactorily in theory for the existence of all the perversions described and to explain their relation to normal sexuality, so called.

In this task we can be helped by a point of view, and by two new evidential observations. The first we owe to Ivan Bloch; according to him, the view that all the perversions are "signs of degeneration" is incorrect; because of the evidence existing that such aberrations from the sexual aim, such erratic relationships to the sexual object, have been manifested since the beginning of time through every age of which we have knowledge, in every race from the most primitive to the most highly civilized, and at times have succeeded in attaining to toleration and general prevalence. The two evidential observations have been made in the course of psycho-analytic investigations of neurotic patients; they must undoubtedly influence our conception of sexual perversions in a decisive manner.

We have said that neurotic symptoms are substitutes for sexual satisfactions and I have already indicated that many difficulties will be met with in proving this statement from the analysis of symptoms. It is, indeed, only accurate if the *perverse* sexual needs, so-called, are included under sexual satisfactions; for an interpretation of the symptoms on this basis is forced upon us with astonishing frequency. The claim made by homosexuals or inverts, that they constitute a select class of mankind, falls at once to the ground when we discover that, in every single neurotic, evidence of homosexual tendencies is forthcoming and that a large proportion of the symptoms are expressions of this latent inversion. Those who openly call themselves homosexuals are merely those in whom the inversion is conscious and manifest; their number is negligible compared with those in whom it is latent. We are bound, in fact, to regard the choice of an object of the same sex as a regular type of offshoot of the capacity to love, and are learning every day more and more to recognize it as especially important. The differences between manifest homosexuality and the normal attitude are certainly not thereby abrogated; they have their practical importance, which remains, but theoretically their value is very considerably dimin-

ished. In fact, we have even come to the conclusion that one particular mental disorder, paranoia, no longer to be reckoned among the transference neuroses, invariably arises from an attempt to subdue unduly powerful homosexual tendencies. Perhaps you will remember that one of our patients,<sup>1</sup> in her obsessive act, played the part of a man—of her own husband, that is, whom she had left; such symptoms, representing the impersonation of a man, are very commonly produced by neurotic women. If this is not actually attributable to homosexuality, it is certainly very closely connected with its origins.

As you probably know, the neurosis of hysteria can create its symptoms in all systems of the body (circulatory, respiratory, etc.) and may thus disturb all the functions. Analysis shows that all those impulses, described as *perverse*, which aim at replacing the genital organ by another come to expression in these symptoms. These organs thus behave as substitutes for the genital organs: it is precisely from the study of hysterical symptoms that we have arrived at the view that, besides their functional rôle, a sexual—*erotogenic*—significance must be ascribed to the bodily organs; and that the needs of the former will be interfered with if the demands of the latter upon them are too great. Countless sensations and innervations, which we meet as hysterical symptoms, in organs apparently not concerned with sexuality, are thus discovered to be essentially fulfilments of perverse sexual desires, by the other organs having usurped the function of the genitalia. In this way also the very great extent to which the organs of nutrition and of excretion, in particular, may serve in yielding sexual excitement is brought home to us. It is indeed the same as is manifested in the perversions; except that in the latter it is unmistakable and recognizable without any difficulty, whereas in hysteria we have to make the detour of interpreting the symptom, and then do not impute the perverse sexual impulse in question to the person's consciousness, but account it to the unconscious part of his personality.

Of the many types of symptoms characteristic of the obsessional neurosis, the most important are found to be brought about by the undue strength of one group of sexual tendencies with a perverted aim, i.e., the sadistic group. These symptoms, in accordance with the structure of the obsessional neurosis, serve mainly as a de-

fence against these wishes or else they express the conflict between satisfaction and rejection. Satisfaction does not find short shrift, however; it knows how to get its own way by a roundabout route in the patient's behaviour, by preference turning against him in self-inflicted torment. Other forms of this neurosis are seen in excessive *worry* and brooding; these are the expressions of an exaggerated sexualization of acts which are normally only preparatory to sexual satisfaction: the desire to see, to touch and to investigate. In this lies the explanation of the very great importance dread of contact and obsessive washing attains to in this disease. An unsuspectedly large proportion of obsessive actions are found to be disguised repetitions and modifications of masturbation, admittedly the only uniform act which accompanies all the varied flights of sexual phantasy.

It would not be difficult to show you the connections between perversion and neurosis in a much more detailed manner, but I believe that I have said enough for our purposes. We must beware, however, of overestimating the frequency and intensity of the perverse tendencies in mankind, after these revelations of their importance in the interpretation of symptoms. You have heard that frustration of normal sexual satisfactions may lead to the development of neurosis. In consequence of this frustration in reality the need is forced into the abnormal paths of sexual excitation. Later you will be able to understand how this happens. You will at any rate understand that a *collateral* damming-up of this kind must swell the force of the perverse impulses, so that they become more powerful than they would have been had no hindrance to normal sexual satisfaction been present in reality. Incidentally, a similar factor may be recognized also in the manifest perversions. In many cases they are provoked or activated by the unduly great difficulties in the way of normal satisfaction of the sexual instinct which are produced either by temporary conditions or by permanent social institutions. In other cases, certainly, perverse tendencies are quite independent of such conditions; they are, as it were, the natural kind of sexual life for the individual concerned.

Perhaps you are momentarily under the impression that all this tends to confuse rather than to explain the relations between normal and perverted sexuality. But keep in mind this consideration. If it is correct that real obstacles to sexual satisfaction or frustration in regard to it bring to the surface perverse tendencies

<sup>1</sup> See p. 553.

in people who would otherwise have shown none, we must conclude that something in these people is ready to embrace the perversions; or, if you prefer it, the tendencies must have been present in them in a latent form. Thus we come to the second of the new evidential observations of which I spoke. Psycho-analytic investigation has found it necessary also to concern itself with the sexual life of children, for the reason that in the analysis of symptoms the forthcoming reminiscences and associations invariably lead back to the earliest years of childhood. That which we discovered in this way has since been corroborated point by point by the direct observation of children. In this way it has been found that all the perverse tendencies have their roots in childhood, that children are disposed towards them all and practise them all to a degree conforming with their immaturity; in short, *perverted sexuality* is nothing else but infantile sexuality, magnified and separated into its component parts.

Now you will see the perversions in an altogether different light and no longer ignore their connection with the sexual life of mankind; but what distressing emotions these astonishing and grotesque revelations will provoke in you! At first you will certainly be tempted to deny everything—the fact that there is anything in children which can be termed sexual life, the accuracy of our observations, and the justification of our claim to see in the behaviour of children any connection with that which in later years is condemned as perverted. Permit me first to explain to you the motives of your antagonism and then to put before you a summary of our observations. That children should have no sexual life—sexual excitement, needs, and gratification of a sort—but that they suddenly acquire these things in the years between twelve and fourteen would be, apart from any observations at all, biologically just as improbable, indeed, nonsensical, as to suppose that they are born without genital organs which first begin to sprout at the age of puberty. What does actually awake in them at this period is the reproductive function, which then makes use for its own purposes of material lying to hand in body and mind. You are making the mistake of confounding sexuality and reproduction with each other and thus you obstruct your own way to the comprehension of sexuality, the perversions, and the neuroses. This mistake, moreover, has a meaning in it. Strange to say, its origin lies in the fact that you yourselves have

all been children and as children were subject to the influence of education. For it is indeed one of the most important social tasks of education to restrain, confine, and subject to an individual control (itself identical with the demands of society) the sexual instinct when it breaks forth in the form of the reproductive function. In its own interests, accordingly, society would postpone the child's full development until it has attained a certain stage of intellectual maturity, since educability practically ceases with the full onset of the sexual instinct. Without this the instinct would break all bounds, and the laboriously erected structure of civilization would be swept away. Nor is the task of restraining it ever an easy one; success in this direction is often poor and, sometimes, only too great. At bottom society's motive is economic; since it has not means enough to support life for its members without work on their part, it must see to it that the number of these members is restricted and their energies directed away from sexual activities on to their work—the eternal primordial struggle for existence, therefore, persisting to the present day.

Experience must have taught educators that the task of moulding the sexual will of the next generation can only be carried out by beginning to impose their influence very early, and intervening in the sexual life of children before puberty, instead of waiting till the storm bursts. Consequently almost all infantile sexual activities are forbidden or made disagreeable to the child; the ideal has been to make the child's life asexual, and in course of time it has come to this that it is really believed to be asexual, and is given out as such, even at the hands of science. In order, then, to avoid any contradiction with established beliefs and aims, the sexual activity of children is overlooked—no small achievement by the way—while science contents itself with otherwise explaining it away. The little child is supposed to be pure and innocent; he who says otherwise shall be condemned as a hardened blasphemer against humanity's tenderest and most sacred feelings.

The children alone take no part in this convention; they assert their animal nature naively enough and demonstrate persistently that they have yet to learn their *purity*. Strange to say, those who deny sexuality in children are the last to relax educative measures against it; they follow up with the greatest severity every manifestation of the *childish tricks* the existence of which they deny. Moreover, it is theo-

retically of great interest that the time of life which most flagrantly contradicts the prejudice about asexual childhood, the years of infancy up to five or six, is precisely the period which is veiled by oblivion in most people's memories; an oblivion which can only be dispelled completely by analysis but which even before this was sufficiently penetrable to allow some of the dreams of childhood to be retained.

I will now tell you the most clearly recognizable of the child's sexual activities. It will be expedient if I first introduce you to the term *libido*. In every way analogous to *hunger*, *libido* is the force by means of which the instinct, in this case the sexual instinct, as, with hunger, the nutritional instinct, achieves expression. Other terms, such as *sexual excitation* and *satisfaction*, require no definition. Interpretation finds most to do in regard to the sexual activities of the infant, as you will easily perceive; and no doubt you will find a reason for objections. This interpretation is formed on the basis of analytic investigation, working backwards from a given symptom. The infant's first sexual excitations appear in connection with the other functions important for life. Its chief interest, as you know, is concerned with taking nourishment; as it sinks asleep at the breast, utterly satisfied, it bears a look of perfect content which will come back again later in life after the experience of the sexual orgasm. This would not be enough to found a conclusion upon. However, we perceive that infants wish to repeat, without really getting any nourishment, the action necessary to taking nourishment; they are therefore not impelled to this by hunger. We call this action *pleasure-sucking* (German: *lutschen*, signifying the enjoyment of sucking for its own sake—as with a rubber comforter); and as when it does this the infant again falls asleep with a blissful expression we see that the action of sucking is sufficient in itself to give it satisfaction. Admittedly, it very soon contrives not to go to sleep without having sucked in this way. An old physician for children in Budapest, Dr. Lindner, was the first to maintain the sexual nature of this procedure. Nurses and people who look after children appear to take the same view of this pleasure-sucking, though without taking up any theoretic attitude about it. They have no doubt that its only purpose is in the pleasure derived; they account it one of the child's *naughty tricks*; and take severe measures to force it to give it up, if it will not do so of its own accord. And so we learn that an

infant performs actions with no other object but that of obtaining pleasure. We believe that this pleasure is first of all experienced while nourishment is being taken, but that the infant learns rapidly to enjoy it apart from this condition. The gratification obtained can only relate to the region of the mouth and lips; we therefore call these areas of the body *erotogenic zones* and describe the pleasure derived from this sucking as a *sexual* one. To be sure, we have yet to discuss the justification for the use of this term.

If the infant could express itself, it would undoubtedly acknowledge that the act of sucking at its mother's breast is far and away the most important thing in life. It would not be wrong in this, for by this act it gratifies at the same moment the two greatest needs in life. Then we learn from psycho analysis, not without astonishment, how much of the mental significance of this act is retained throughout life. Sucking for nourishment becomes the point of departure from which the whole sexual life develops, the unattainable prototype of every later sexual satisfaction, to which in times of need phantasy often enough reverts. The desire to suck includes within it the desire for the mother's breast, which is therefore the first *object* of sexual desire; I cannot convey to you any adequate idea of the importance of this first object in determining every later object adopted, of the profound influence it exerts, through transformation and substitution, upon the most distant fields of mental life. First of all, however, as the infant takes to sucking for pleasure this object is given up and is replaced by a part of its own body; it sucks its thumb or its own tongue. For purposes of obtaining pleasure it thus makes itself independent of the concurrence of the outer world and, in addition, it extends the region of excitation to a second area of the body, thus intensifying it. The erotogenic zones are not all equally capable of yielding enjoyment; it is therefore an important experience when, as Dr. Lindner says, the infant in feeling about on its own body discovers the particularly excitable region of its genitalia, and so finds the way from pleasure-sucking to onanism.

This assessment of the nature of pleasure-sucking has now brought to our notice two of the decisive characteristics of infantile sexuality. It appears in connection with the satisfaction of the great organic needs, and it behaves *auto-erotically*, that is to say, it seeks and finds its objects in its own person. What is

most clearly discernible in regard to the taking of nourishment is to some extent repeated with the process of excretion. We conclude that infants experience pleasure in the evacuation of urine and the contents of the bowels, and that they very soon endeavour to contrive these actions so that the accompanying excitation of the membranes in these erotogenic zones may secure them the maximum possible gratification. As Lou Andreas has pointed out, with fine intuition, the outer world first steps in as a hindrance at this point, a hostile force opposed to the child's desire for pleasure—the first hint he receives of external and internal conflicts to be experienced later on. He is not to pass his excretions whenever he likes but at times appointed by other people. To induce him to give up these sources of pleasure he is told that everything connected with these functions is *improper*, and must be kept concealed. In this way he is first required to exchange pleasure for value in the eyes of others. His own attitude to the excretions is at the outset very different. His own fæces produce no disgust in him; he values them as part of his own body and is unwilling to part with them, he uses them as the first present by which he can mark out those people whom he values especially. Even after education has succeeded in alienating him from these tendencies, he continues to feel the same high regard for his presents and his money; while his achievements in the way of urination appear to be the subject of particular pride.

I know that for some time you have been longing to interrupt me with cries of: "Enough of these monstrosities! The motions of the bowels a source of pleasurable sexual satisfaction exploited even by infants! Fæces a substance of great value and the anus a kind of genital organ! We do not believe it; but we understand why children's physicians and educationists have emphatically rejected psycho-analysis and its conclusions!" Not at all; you have merely forgotten for the moment that I have been endeavouring to show you the connection between the actual facts of infantile sexual life and the actual facts of the sexual perversions. Why should you not know that in many adults, both homosexual and heterosexual, the anus actually takes over the part played by the vagina in sexual intercourse? And that there are many persons who retain the pleasurable sensations accompanying evacuations of the bowels throughout life and describe them as far from insignificant? You may

hear from children themselves, when they are a little older and able to talk about these things, what an interest they take in the act of defæcation and what pleasure they find in watching others in the act. Of course if you have previously systematically intimidated these children they will understand very well that they are not to speak of such things. And for all else that you refuse to believe I refer you to the evidence brought out in analysis and to the direct observation of children and I tell you that it will require the exercise of considerable ingenuity to avoid seeing all this or to see it in a different light. Nor am I at all averse from your thinking the relationship between childish sexual activities and the sexual perversions positively striking. It is a matter of course that there should be this relationship; for if a child has a sexual life at all it must be of a perverted order, since, apart from a few obscure indications, he is lacking in all that transforms sexuality into the reproductive function. Moreover, it is a characteristic common to all the perversions that in them reproduction as an aim is put aside. This is actually the criterion by which we judge whether a sexual activity is perverse—if it departs from reproduction in its aims and pursues the attainment of gratification independently. You will understand therefore that the gulf and turning-point in the development of the sexual life lies at the point of its subordination to the purposes of reproduction. Everything that occurs before this conversion takes place, and everything which refuses to conform to it and serves the pursuit of gratification alone, is called by the unhonoured title of *perversion* and as such is despised.

So let me continue my brief account of infantile sexuality. I could supplement what I have told you concerning two of the bodily systems by extending the same scrutiny to the others. The sexual life of the child consists entirely in the activities of a series of component-instincts which seek for gratification independently of one another, some in his own body and others already in an external object. Among the organs of these bodily systems the genitalia rapidly take the first place; there are people in whom pleasurable gratification in their own genital organ, without the aid of any other genital organ or object, is continued without interruption from the onanism habitual in the suckling period of infancy to the onanism of necessity occurring in the years of puberty, and then maintained indefinitely be-

yond that. Incidentally, the subject of onanism is not so easily exhausted; it contains material for consideration from various angles.

In spite of my wish to limit the extent of this discussion I must still say something about sexual curiosity in children. It is too characteristic of childish sexuality and too important for the symptom-formation of the neuroses to be omitted. Infantile sexual curiosity begins very early, sometimes before the third year. It is not connected with the difference between the sexes, which is nothing to children, since they—boys, at least—ascribe the same male genital organ to both sexes. If, then, a boy discovers the vagina in a little sister or playmate, he at once tries to deny the evidence of his senses, for he cannot conceive of a human being like himself without his most important attribute. Later, he is horrified at the possibilities it reveals to him; the influence of previous threats occasioned by too great a preoccupation with his own little member now begins to be felt. He comes under the dominion of the castration complex, which will play such a large part in the formation of his character if he remains healthy, and of his neurosis if he falls ill, and of his resistances if he comes under analytic treatment. Of little girls we know that they feel themselves heavily handicapped by the absence of a large visible penis and envy the boy's possession of it; from this source primarily springs the wish to be a man which is resumed again later in the neurosis, owing to some mal-adjustment to a female development. The clitoris in the girl, moreover, is in every way equivalent during childhood to the penis; it is a region of especial excitability in which auto-erotic satisfaction is achieved. In the transition to womanhood very much depends upon the early and complete relegation of this sensitivity from the clitoris over to the vaginal orifice. In those women who are sexually anaesthetic, as it is called, the clitoris has stubbornly retained this sensitivity.

The sexual interest of children is primarily directed to the problem of birth—the same problem that lies behind the riddle of the Theban Sphinx. This curiosity is for the most part aroused by egoistic dread of the arrival of another child. The answer which the nursery has ready for the child, that the stork brings the babies, meets with incredulity even in little children much more often than we imagine. The feeling of having been deceived by grown-up people, and put off with lies, contributes greatly to a sense of isolation and to the de-

velopment of independence. But the child is not able to solve this problem on his own account. His undeveloped sexual constitution sets definite limits to his capacity to understand it. He first supposes that children are made by mixing some special thing with the food taken; nor does he know that only women can have children. Later, he learns of this limitation and gives up the idea of children being made by food, though it is retained in fairy-tales. A little later he soon sees that the father must have something to do with making babies, but he cannot discover what it is. If by chance he is witness of the sexual act he conceives it as an attempt to overpower the woman, as a combat, the sadistic misconception of coitus; at first, however, he does not connect this act with the creation of children; if he discovers blood on the mother's bed or under-linen he takes it as evidence of injury inflicted by the father. In still later years of childhood he probably guesses that the male organ of the man plays an essential part in the procreation of children, but cannot ascribe to this part of the body any function but that of urination.

Children are all united from the outset in the belief that the birth of a child takes place by the bowel; that is to say, that the baby is produced like a piece of faeces. Not until all interest has been weaned from the anal region is this theory abandoned and replaced by the supposition that the navel opens, or that the area between the two nipples is the birthplace of the child. In some such manner as this the enquiring child approaches some knowledge of the facts of sex, unless, misled by his ignorance, he overlooks them until he receives an imperfect and discrediting account of them, usually in the period before puberty, which not infrequently affects him traumatically.

Now you will probably have heard that the term *sexual* has suffered an unwarrantable expansion of meaning at the hands of psycho-analysis, in order that its assertions regarding the sexual origin of the neuroses and the sexual significance of the symptoms may be maintained. You can now judge for yourselves whether this amplification is justified or not. We have extended the meaning of the concept *sexuality* only so far as to include the sexual life of perverted persons and also of children; that is to say, we have restored to it its true breadth of meaning. What is called *sexuality* outside psycho-analysis applies only to the restricted sexual life that is subordinated to the reproductive function and is called *normal*.

## TWENTY-FIRST LECTURE

## DEVELOPMENT OF THE LIBIDO AND SEXUAL ORGANIZATIONS

IT is my impression that I have not succeeded in bringing home to you with complete conviction the importance of the perversions for our conception of sexuality. I wish therefore, as far as I am able, to review and improve upon what I have already said on this subject.

Now I do not wish you to think that it was the perversions alone that required us to make the alteration in the meaning of the term sexuality which has aroused such vehement opposition. The study of infantile sexuality has contributed even more to it, and the unanimity between the two was decisive. But, however unmistakably they may be in the later years of childhood, the manifestations of infantile sexuality in its earliest forms do seem to fade away indefinitely. Those who do not wish to pay attention to evolution and to the connections brought out by analysis will dispute the sexual nature of them, and will ascribe in consequence some other, undifferentiated character to them. You must not forget that as yet we have no generally acknowledged criterion for the sexual nature of a phenomenon, unless it is some connection with the reproductive function—a definition which we have had to reject as too narrow. The biological criteria, such as the periodicities of twenty-three and twenty-eight days, suggested by W. Fliess, are exceedingly debatable; the peculiar chemical features which we may perhaps assume for sexual purposes are yet to be discovered. The sexual perversions in adults, on the other hand, are something definite and unambiguous. As their generally accepted description implies, they are unquestionably of a sexual nature; whether you call them marks of degeneration or anything else, no one has yet been so bold as to rank them anywhere but among the phenomena of sexual life. In view of them alone we are justified in maintaining that sexuality and the reproductive function are not identical, for they one and all abjure the aim of reproduction.

I notice a not uninteresting parallel here. Whereas, for most people, the word *mental* means *conscious*, we found ourselves obliged to widen the application of the term *mental* to include a part of the mind that is not conscious. In a precisely similar way, most people declare *sexual* identical with *pertaining to reproduction*—or, if you like it expressed more concisely,

with *genital*; whereas we cannot avoid admitting things as *sexual* that are not *genital* and have nothing to do with reproduction. It is only a formal analogy, but it is not without deeper significance.

However, if the existence of sexual perversions is such a forcible argument on this point, why has it not long ago done its work and settled the question? I really am unable to say. It seems to me that the sexual perversions have come under a very special ban, which insinuates itself into the theory, and interferes even with scientific judgment on the subject. It seems as if no one could forget, not merely that they are detestable, but that they are also something monstrous and terrifying; as if they exerted a seductive influence; as if at bottom a secret envy of those who enjoy them had to be strangled—the same sort of feeling that is confessed by the count who sits in judgment in the famous parody of *Tannhäuser*:

*So in the Mount of Venus conscience, duty, are forgot!*

*—Remarkable that such a thing has never been my lot!*

In reality, perverts are more likely to be poor devils who have to pay most bitterly for the satisfaction they manage to procure with such difficulty.

That which makes perverse activities so unmistakably sexual, in spite of all that seems unnatural in their objects or their aims, is the fact that in perverse satisfaction the act still terminates usually in a complete orgasm with evacuation of the genital product. This is of course only the consequence of adult development in the persons concerned; in children, orgasm and genital excretion are not very well possible; as substitutes they have approximations to them which are again not recognized definitely as sexual.

I must still add something more in order to complete our assessment of the sexual perversions. Abominated as they are, sharply distinguished from normal sexual activity as they may be, simple observation will show that very rarely is one feature or another of them absent from the sexual life of a normal person. The kiss, to begin with, has some claim to be called a perverse act, for it consists of the union of the two erotogenic mouth zones instead of the two genital organs. But no one condemns it as perverse; on the contrary, in the theatre it is permitted as a refined indication of the sexual act. Nevertheless, kissing is a thing that can

easily become an absolute perversion—namely, when it occurs in such intensity that orgasm and emission directly accompany it, which happens not at all uncommonly. Further, it will be found that gazing at and handling the object are in one person an indispensable condition of sexual enjoyment, while another at the height of sexual excitement pinches or bites; that in another lover not always the genital region, but some other bodily region in the object, provokes the greatest excitement, and so on in endless variety. It would be absurd to exclude people with single idiosyncrasies of this kind from the ranks of the normal and place them among perverts; rather, it becomes more and more clear that what is essential to the perversions lies, not in the overstepping of the sexual aim, not in the replacement of the genitalia, not always even in the variations in the object, but solely in the *exclusiveness* with which these deviations are maintained, so that the sexual act which serves the reproductive process is rejected altogether. In so far as perverse performances are included in order to intensify or to lead up to the performance of the normal sexual act, they are no longer actually perverse. Facts of the kind just described naturally tend to diminish the gulf between normal and perverse sexuality very considerably. The obvious inference is that normal sexuality has arisen, out of something existing prior to it, by a process of discarding some components of this material as useless, and by combining the others so as to subordinate them to a new aim, that of reproduction.

The point of view thus gained in regard to the perversions can now be employed by us in penetrating more deeply, with a clear perspective, into the problem of infantile sexuality; but before doing this I must draw your attention to an important difference between the two. Perverse sexuality is as a rule exceedingly concentrated, its whole activity is directed to one—and mostly to only one—aim; one particular component-impulse is supreme; it is either the only one discernible or it has subjected the others to its own purposes. In this respect there is no difference between perverse and normal sexuality, except that the dominating component-impulse, and therefore the sexual aim, is a different one. Both of them constitute a well-organized tyranny; only that in one case one ruling family has usurped all the power, and in the other, another. This concentration and organization, on the other hand, is in the main absent from infantile sexuality; its component-

impulses are equally valid, each of them strives independently after its own pleasure. Both the lack of this concentration (in childhood) and the presence of it (in the adult) correspond well with the fact that both normal and perverse sexuality are derived from the same source, namely, infantile sexuality. There are indeed also cases of perversion which correspond even more closely to infantile sexuality in that numerous component-instincts, independently of one another, with their aims, are developed or, better, perpetuated in them. With these cases it is more correct to speak of infantilism than of perversion of the sexual life.

Thus prepared we may now go on to consider a suggestion which we shall certainly not be spared. It will be said: "Why are you so set upon declaring as already belonging to sexuality those indefinite manifestations of childhood out of which what is sexual later develops, and which you yourself admit to be indefinite? Why are you not content rather to describe them physiologically and simply to say that activities, such as sucking for its own sake and the retaining of excreta, may be observed already in young infants, showing that they seek *pleasure in their organs*? In that way you would have avoided the conception of a sexual life even in babies which is so repugnant to all our feelings." Well, I can only answer that I have nothing against pleasure derived from the organs of the body; I know indeed that the supreme pleasure of the sexual union is also only a bodily pleasure, derived from the activity of the genital organ. But can you tell me when this originally indifferent bodily pleasure acquires the sexual character that it undoubtedly possesses in later phases of development? Do we know any more about this *organ-pleasure* than we know about sexuality? You will answer that the sexual character is added to it when the genitalia begin to play their part; sexuality simply means genital. You will even evade the obstacle of the perversions by pointing out that after all with most of them a genital orgasm occurs, although brought about by other means than the union of the genitalia. If you were to eliminate the relation to reproduction from the essential characteristics of sexuality since this view is untenable in consequence of the existence of the perversions, and were to emphasize instead activity of the genital organs, you would actually take up a much better position. But then we should no longer differ very widely; it would be a case of the genital organs *versus* the other

organs. What do you now make of the abundant evidence that the genital organs may be replaced by other organs for the purpose of gratification, as in the normal kiss, or the perverse practices of loose living, or in the symptomatology of hysteria? In this neurosis it is quite usual for stimulation phenomena, sensations, innervations, and even the processes of erection, which properly belong to the genitalia to be displaced on to other distant areas of the body (e.g., the displacement from below upwards to the head and face). Thus you will find that nothing is left of all that you cling to as essentially characteristic of sexuality; and you will have to make up your minds to follow my example and extend the designation *sexual* to include those activities of early infancy which aim at *organ-pleasure*.

And now will you permit me to bring forward two further considerations in support of my view. As you know, we call the doubtful and indefinable activities of earliest infancy towards pleasure *sexual*, because in the course of analysing symptoms we reach them by way of material that is undeniably sexual. They would not thereby necessarily be sexual themselves, let us grant; but let us take an analogous case. Suppose that there were no way to observe the development from seed of two dicotyledonous plants—the apple-tree and the bean; but imagine that in both it was possible to follow back its development from the fully developed plant to the first seedling with two cotyledons. The two cotyledons are indistinguishable in each; they look exactly alike in both plants. Shall I conclude from this that they actually are exactly alike and that the specific differences between apple-tree and bean-plant arise *later* in the plant's development? Or is it not more correct biologically to believe that this difference exists *already* in the seedlings, although I cannot see any in the cotyledons? This is what we do when we call infantile pleasurable activities sexual. Whether each and every organ-pleasure may be called sexual or whether there exists, besides the sexual, another kind of pleasure that does not deserve this name is a matter I cannot discuss here. I know too little about organ-pleasure and its conditions; and I am not at all surprised that, in consequence of the retrogressive character of analysis, I arrive finally at factors which at the present time do not permit of definite classification.

One thing more. You have on the whole gained very little for what you are so eager to

maintain, the sexual purity of children, even if you can convince me that the infant's activities had better not be regarded as sexual. For from the third year onwards there is no longer any doubt about sexual life in the child; at this period the genital organs begin already to show signs of excitation; there is perhaps a regular period of infantile masturbation, that is, of gratification in the genital organs. The mental and social sides of sexual life need no longer be overlooked: choice of object, distinguishing of particular persons with affection, even decision in favour of one sex or the other, and jealousy, were conclusively established independently by impartial observation before the time of psycho-analysis; they may be confirmed by any observer who will use his eyes. You will object that you never doubted the early awakening of affection but only that this affection was of a *sexual* quality. Children between the ages of three and eight have certainly learnt to conceal this element in it; but nevertheless if you look attentively you will collect enough evidence of the *sensual* nature of this affection, and whatever still escapes your notice will be amply and readily supplied by analytic investigation. The sexual aims in this period of life are in closest connection with the sexual curiosity arising at the same time, of which I have given you some description. The perverse character of some of these aims is a natural result of the immature constitution of the child who has not yet discovered the aim of the act of intercourse.

From about the sixth or eighth year onwards a standstill or retrogression is observed in the sexual development, which in those cases reaching a high cultural standard deserves to be called a *latency period*. This latency period, however, may be absent; nor does it necessarily entail an interruption of sexual activities and sexual interests over the whole field. Most of the mental experiences and excitations occurring before the latency period then succumb to the infantile amnesia, already discussed, which veils our earliest childhood from us and estranges us from it. It is the task of every psycho-analysis to bring this forgotten period of life back into recollection; one cannot resist the supposition that the beginnings of sexual life belonging to this period are the motive for this forgetting, that is, that this oblivion is an effect of repression.

From the third year onwards, the sexual life of children shows much in common with that of adults; it is differentiated from the latter, as

we already know, by the absence of a stable organization under the primacy of the genital organs, by inevitable traits of a perverse order, and of course also by far less intensity in the whole impulse. But those phases of the sexual development, or as we will call it, of the *libido-development*, which are of greatest interest theoretically lie before this period. This development is gone through so rapidly that direct observation alone would perhaps never have succeeded in determining its fleeting forms. Only by the help of psycho-analytic investigation of the neuroses has it become possible to penetrate so far back and to discover these still earlier phases of libido-development. These phases are certainly only theoretic constructions, but in the practice of psycho-analysis you will find them necessary and valuable constructions. You will soon understand how it happens that a pathological condition enables us to discover phenomena which we should certainly overlook in normal conditions.

Thus we can now define the forms taken by the sexual life of the child before the primacy of the genital zone is reached; this primacy is prepared for in the early infantile period, before the latent period, and is premanently organized from puberty onwards. In this early period a loose sort of organization exists which we shall call *pre-genital*; for during this phase it is not the genital component-instincts, but the *sadistic* and *anal*, which are most prominent. The contrast between *masculine* and *feminine* plays no part as yet; instead of it there is the contrast between *active* and *passive*, which may be described as the forerunner of the sexual polarity with which it also links up later. That which in this period seems masculine to us, regarded from the stand-point of the genital phase, proves to be the expression of an impulse to mastery, which easily passes over into cruelty. Impulses with a passive aim are connected with the erotogenic zone of the rectal orifice, at this period very important; the impulses of skoptophilia (gazing) and curiosity are powerfully active; the function of excreting urine is the only part actually taken by the genital organ in the sexual life. Objects are not wanting to the component-instincts in this period, but these objects are not necessarily all comprised in one object. The sadistic-anal organization is the stage immediately preceding the phase of primacy of the genital zone. Closer study reveals how much of it is retained intact in the later final structure, and what are the paths by which these component-instincts are

forced into the service of the new *genital organization*. Behind the sadistic-anal phase of the libido-development we obtain a glimpse of an even more primitive stage of development, in which the erotogenic mouth zone plays the chief part. You can guess that the sexual activity of sucking (for its own sake) belongs to this stage; and you may admire the understanding of the ancient Egyptians in whose art a child, even the divine Horus, was represented with a finger in the mouth. Abraham has quite recently published work showing that traces of this primitive *oral* phase of development survive in the sexual life of later years.

I can indeed imagine that you will have found this last information about the sexual organizations less of an enlightenment than an inflection. Perhaps I have again gone too much into detail; but have patience! what you have just heard will be of more use when we employ it later. Keep in view at the moment the idea that the sexual life—the *libido-function*, as we call it—does not first spring up in its final form, does not even expand along the lines of its earliest forms, but goes through a series of successive phases unlike one another; in short, that many changes occur in it, like those in the development of the caterpillar into the butterfly. The turning-point of this development is the *subordination of all the sexual component-instincts under the primacy of the genital zone* and, together with this, the enrolment of sexuality in the service of the reproductive function. Before this happens the sexual life is, so to say, disparate—independent activities of single component-impulses each seeking *organ-pleasure* (pleasure in a bodily organ). This anarchy is modified by attempts at *pre-genital organizations*, of which the chief is the sadistic-anal phase, behind which is the oral, perhaps the most primitive. In addition there are the various processes, about which little is known as yet, which effect the transition from one stage of organization to the next above it. Of what significance this long journey over so many stages in the development of the libido is for comprehension of the neuroses we shall learn later on.

Today we will follow up another aspect of this development—namely, the relation of the sexual component-impulses to an *object*; or, rather, we will take a fleeting glimpse over this development so that we may spend more time upon a comparatively late result of it. Certain of the component-impulses of the sexual instinct have an object from the very beginning

and hold fast to it: such are the impulses to mastery (sadism), to gazing (skoptophilia) and curiosity. Others, more plainly connected with particular erotogenic areas in the body, only have an object in the beginning, so long as they are still dependent upon the non-sexual functions, and give it up when they become detached from these later. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nutrition. In the act of sucking for its own sake the erotic component, also gratified in sucking for nutrition, makes itself independent, gives up the object in an external person, and replaces it by a part of the child's own person. The oral impulse becomes *auto-erotic*, as the anal and other erotogenic impulses are from the beginning. Further development has, to put it as concisely as possible, two aims: first, to renounce auto-erotism, to give up again the object found in the child's own body in exchange again for an external one; and secondly, to combine the various objects of the separate impulses and replace them by one single one. This naturally can only be done if the single object is again itself complete, with a body like that of the subject; nor can it be accomplished without some part of the auto-erotic impulse-excitations being abandoned as useless.

The processes by which an object is found are rather involved, and have not so far received comprehensive exposition. For our purposes it may be emphasized that, when the process has reached a certain point in the years of childhood before the latency period, the object adopted proves almost identical with the first object of the oral pleasure impulse, adopted by reason of the child's dependent relationship to it; it is, namely, the mother, although not the mother's breast. We call the mother the first *love-object*. We speak of *love* when we lay the accent upon the mental side of the sexual impulses and disregard, or wish to forget for a moment, the demands of the fundamental physical or *sensual* side of the impulses. At about the time when the mother becomes the love-object, the mental operation of repression has already begun in the child and has withdrawn from him the knowledge of some part of his sexual aims. Now with this choice of the mother as love-object is connected all that which, under the name of the *Oedipus complex*, has become of such great importance in the psycho-analytic explanation of the neuroses, and which has had a perhaps equally important

share in causing the opposition against psycho-analysis.

Here is a little incident which occurred during the present war. One of the staunch adherents of psycho-analysis was stationed in his medical capacity on the German front in Poland; he attracted the attention of his colleagues by the fact that he occasionally effected an unexpected influence upon a patient. On being questioned, he admitted that he worked with psycho-analytic methods and with readiness agreed to impart his knowledge to his colleagues. So every evening the medical men of the corps, his colleagues and superiors, met to be initiated into the mysteries of psycho-analysis. For a time all went well; but when he had introduced his audience to the Oedipus complex a superior officer rose and announced that he did not believe this, it was the behaviour of a cad for the lecturer to relate such things to brave men, fathers of families, who were fighting for their country, and he forbade the continuation of the lectures. This was the end; the analyst got himself transferred to another part of the front. In my opinion, however, it is a bad outlook if a victory for German arms depends upon an organization of science such as this, and German science will not prosper under any such organization.

Now you will be impatiently waiting to hear what this terrible Oedipus complex comprises. The name tells you: you all know the Greek myth of King Oedipus, whose destiny it was to slay his father and to wed his mother, who did all in his power to avoid the fate prophesied by the oracle, and who in self-punishment blinded himself when he discovered that in ignorance he had committed both these crimes. I trust that many of you have yourselves experienced the profound effect of the tragic drama fashioned by Sophocles from this story. The Attic poet's work portrays the gradual discovery of the deed of Oedipus, long since accomplished, and brings it slowly to light by skilfully prolonged enquiry, constantly fed by new evidence; it has thus a certain resemblance to the course of a psycho-analysis. In the dialogue, the deluded mother-wife, Jocasta, resists the continuation of the enquiry; she points out that many people in their dreams have mated with their mothers, but that dreams are of no account. To us dreams are of much account, especially typical dreams which occur in many people; we have no doubt that the dream Jocasta speaks of is intimately related to the shocking and terrible story of the myth.

It is surprising that Sophocles' tragedy does not call forth indignant remonstrance in its audience; this reaction would be much better justified in them than it was in the blunt army doctor. For at bottom it is an immoral play; it sets aside the individual's responsibility to social law, and displays divine forces ordaining the crime and rendering powerless the moral instincts of the human being which would guard him against the crime. It would be easy to believe that an accusation against destiny and the gods was intended in the story of the myth; in the hands of the critical Euripides, at variance with the gods, it would probably have become such an accusation. But with the reverent Sophocles there is no question of such an intention; the pious subtlety which declares it the highest morality to bow to the will of the gods, even when they ordain a crime, helps him out of the difficulty. I do not believe that this moral is one of the virtues of the drama, but neither does it detract from its effect; it leaves the hearer indifferent; he does not react to this, but to the secret meaning and content of the myth itself. He reacts as though by self-analysis he had detected the Oedipus complex in himself, and had recognized the will of the gods and the oracle as glorified disguises of his own unconscious; as though he remembered in himself the wish to do away with his father and in his place to wed his mother, and must abhor the thought. The poet's words seem to him to mean: "In vain do you deny that you are accountable, in vain do you proclaim how you have striven against these evil designs. You are guilty, nevertheless; for you could not stifle them; they still survive unconsciously in you." And psychological truth is contained in this; even though man has repressed his evil desires into his Unconscious and would then gladly say to himself that he is no longer answerable for them, he is yet compelled to feel his responsibility in the form of a sense of guilt for which he can discern no foundation.

There is no possible doubt that one of the most important sources of the sense of guilt which so often torments neurotic people is to be found in the Oedipus complex. More than this: in 1913, under the title of *Totem and Taboo*, I published a study of the earliest forms of religion and morality in which I expressed a suspicion that perhaps the sense of guilt of mankind as a whole, which is the ultimate source of religion and morality, was acquired in the beginnings of history through the Oedipus complex. I should much like to tell you

more of this, but I had better not; it is difficult to leave this subject when once one begins upon it, and we must return to individual psychology.

Now what does direct observation of children, at the period of object-choice before the latency period, show us in regard to the Oedipus complex? Well, it is easy to see that the little man wants his mother all to himself, finds his father in the way, becomes restive when the latter takes upon himself to caress her, and shows his satisfaction when the father goes away or is absent. He often expresses his feelings directly in words and promises his mother to marry her; this may not seem much in comparison with the deeds of Oedipus, but it is enough in fact; the kernel of each is the same. Observation is often rendered puzzling by the circumstance that the same child on other occasions at this period will display great affection for the father; but such contrasting—or, better, *ambivalent*—states of feeling, which in adults would lead to conflicts, can be tolerated alongside one another in the child for a long time, just as later on they dwell together permanently in the unconscious. One might try to object that the little boy's behaviour is due to egoistic motives and does not justify the conception of an erotic complex; the mother looks after all the child's needs and consequently it is to the child's interest that she should trouble herself about no one else. This too is quite correct; but it is soon clear that in this, as in similar dependent situations, egoistic interests only provide the occasion on which the erotic impulses seize. When the little boy shows the most open sexual curiosity about his mother, wants to sleep with her at night, insists on being in the room while she is dressing, or even attempts physical acts of seduction, as the mother so often observes and laughingly relates, the erotic nature of this attachment to her is established without a doubt. Moreover, it should not be forgotten that a mother looks after a little daughter's needs in the same way without producing this effect; and that often enough a father eagerly vies with her in trouble for the boy without succeeding in winning the same importance in his eyes as the mother. In short, the factor of sex preference is not to be eliminated from the situation by any criticisms. From the point of view of the boy's egoistic interests, it would merely be foolish if he did not tolerate two people in his service rather than only one of them.

As you see, I have only described the rela-

tionship of a boy to his father and mother; things proceed in just the same way, with the necessary reversal, in little girls. The loving devotion to the father, the need to do away with the superfluous mother and to take her place, the early display of coquetry and the arts of later womanhood, make up a particularly charming picture in a little girl, and may cause us to forget its seriousness and the grave consequences which may later result from this situation. Let us not fail to add that frequently the parents themselves exert a decisive influence upon the awakening of the Oedipus complex in a child, by themselves following the sex attraction where there is more than one child; the father in an unmistakable manner prefers his little daughter with marks of tenderness, and the mother, the son: but even this factor does not seriously impugn the spontaneous nature of the infantile Oedipus complex. When other children appear, the Oedipus complex expands and becomes a family complex. Reinforced anew by the injury resulting to the egoistic interests, it actuates a feeling of aversion towards these new arrivals and an unhesitating wish to get rid of them again. These feelings of hatred are as a rule much more often openly expressed than those connected with the parental complex. If such a wish is fulfilled and after a short time death removes the unwanted addition to the family, later analysis can show what a significant event this death is for the child, although it does not necessarily remain in memory. Forced into the second place by the birth of another child and for the first time almost entirely parted from the mother, the child finds it very hard to forgive her for this exclusion of him; feelings which in adults we should describe as profound embitterment are roused in him, and often become the groundwork of a lasting estrangement. That sexual curiosity and all its consequences is usually connected with these experiences has already been mentioned. As these new brothers and sisters grow up the child's attitude to them undergoes the most important transformations. A boy may take his sister as love-object in place of his faithless mother; where there are several brothers to win the favour of a little sister hostile rivalry, of great importance in after life, shows itself already in the nursery. A little girl takes an older brother as a substitute for the father who no longer treats her with the same tenderness as in her earliest years; or she takes a little sister as a substitute for the child that she vainly wished for from her father.

So much and a great deal more of a similar kind is shown by direct observation of children, and by consideration of clear memories of childhood, uninfluenced by any analysis. Among other things you will infer from this that a child's position in the sequence of brothers and sisters is of very great significance for the course of his later life, a factor to be considered in every biography. What is even more important, however, is that in the face of these enlightening considerations, so easily to be obtained, you will hardly recall without smiling the scientific theories accounting for the prohibition of incest. What has not been invented for this purpose! We are told that sexual attraction is diverted from the members of the opposite sex in one family owing to their living together from early childhood; or that a biological tendency against in-breeding has a mental equivalent in the horror of incest! Whereby it is entirely overlooked that no such rigorous prohibitions in law and custom would be required if any trustworthy natural barriers against the temptation to incest existed. The opposite is the truth. The first choice of object in mankind is regularly an incestuous one, directed to the mother and sister of men, and the most stringent prohibitions are required to prevent this sustained infantile tendency from being carried into effect. In the savage and primitive peoples surviving today the incest prohibitions are a great deal stricter than with us; Theodor Reik has recently shown in a brilliant work that the meaning of the savage rites of puberty, which represent re-birth, is the loosening of the boy's incestuous attachment to the mother and his reconciliation with the father.

Mythology will show you that incest, ostensibly so much abhorred by men, is permitted to their gods without a thought; and from ancient history you may learn that incestuous marriage with a sister was prescribed as a sacred duty for kings (the Pharaohs of Egypt and the Incas of Peru); it was therefore in the nature of a privilege denied to the common herd.

Incest with the mother is one of the crimes of Oedipus and parricide the other. Incidentally, these are the two great offences condemned by totemism, the first social-religious institution of mankind. Now let us turn from the direct observation of children to the analytic investigation of adults who have become neurotic; what does analysis yield in further knowledge of the Oedipus complex? Well, this is soon told. The complex is revealed just as the myth re-

lates it; it will be seen that every one of these neurotics was himself an Oedipus or, what amounts to the same thing, has become a Hamlet in his reaction to the complex. To be sure, the analytic picture of the Oedipus complex is an enlarged and accentuated edition of the infantile sketch; the hatred of the father and the death-wishes against him are no longer vague hints, the affection for the mother declares itself with the aim of possessing her as a woman. Are we really to accredit such grossness and intensity of the feelings to the tender age of childhood; or does the analysis deceive us by introducing another factor? It is not difficult to find one. Every time anyone describes anything past, even if he be a historian, we have to take into account all that he unintentionally imports into that past period from present and intermediate times, thereby falsifying it. With the neurotic it is even doubtful whether this retroversion is altogether unintentional; we shall hear later on that there are motives for it and we must explore the whole subject of the *retrogressive phantasy-making* which goes back to the remote past. We soon discover, too, that the hatred against the father has been strengthened by a number of motives arising in later periods and other relationships in life, and that the sexual desires towards the mother have been moulded into forms which would have been as yet foreign to the child. But it would be a vain attempt if we endeavoured to explain the whole of the Oedipus complex by *retrogressive phantasy-making*, and by motives originating in later periods of life. The infantile nucleus with more or less of the accretions to it, remains intact, as is confirmed by direct observation of children.

The clinical fact which confronts us behind the form of the Oedipus complex as established by analysis now becomes of the greatest practical importance. We learn that at the time of puberty, when the sexual instinct first asserts its demand in full strength, the older familiar incestuous objects are taken up again, and again invested by the libido. The infantile object-choice was but a feeble venture in play, as it were, but it laid down the direction for the object-choice of puberty. At this time a very intense flow of feeling towards the Oedipus complex or in reaction to it comes into force; since their mental antecedents have become intolerable, however, these feelings must remain for the most part outside consciousness. From the time of puberty onward the human

individual must devote himself to the great task of *freeing himself from the parents*; and only after this detachment is accomplished can he cease to be a child and so become a member of the social community. For a son, the task consists in releasing his libidinal desires from his mother, in order to employ them in the quest of an external love-object in reality; and in reconciling himself with his father if he has remained antagonistic to him, or in freeing himself from his domination if, in the reaction to the infantile revolt, he has lapsed into subservience to him. These tasks are laid down for every man; it is noteworthy how seldom they are carried through ideally, that is, how seldom they are solved in a manner psychologically as well as socially satisfactory. In neurotics, however, this detachment from the parents is not accomplished at all; the son remains all his life in subjection to his father, and incapable of transferring his libido to a new sexual object. In the reversed relationship the daughter's fate may be the same. In this sense the Oedipus complex is justifiably regarded as the kernel of the neuroses.

You will imagine how incompletely I am sketching a large number of the connections bound up with the Oedipus complex which practically and theoretically are of great importance. I shall not go into the variations and possible inversions of it at all. Of its less immediate effects I should like to allude to one only, which proves it to have influenced literary production in a far-reaching manner. Otto Rank has shown in a very valuable work that dramatists throughout the ages have drawn their material principally from the Oedipus and incest complex and its variations and masked forms. It should also be remarked that long before the time of psycho-analysis the two criminal offences of Oedipus were recognized as the true expressions of unbridled instinct. Among the works of the Encyclopaedist Diderot you will find the famous dialogue, *Le neveu de Rameau*, which was translated into German by no less a person than Goethe. There you may read these remarkable words: *Si le petit sauvage était abandonné à lui-même, qu'il conserva toute son imbecillité et qu'il réunit au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le cou à son père et coucherait avec sa mère.*<sup>1</sup>

<sup>1</sup> If the young savage were left to himself, so that he could keep all his foolishness and could unite to the slight reason of the baby in the crib the violent emotions of a man of thirty, he would wring the neck of his father and go to bed with his mother—Ed.

There is yet one thing more which I cannot pass over. The mother-wife of Oedipus must not remind us of dreams in vain. Do you still remember the results of our dream-analyses, how so often the dream-forming wishes proved perverse and incestuous in their nature, or betrayed an unsuspected enmity to near and beloved relatives? We then left the source of these evil strivings of feeling unexplained. Now you can answer this question yourselves. They are dispositions of the libido, and investments of objects by libido, belonging to early infancy and long since given up in conscious life, but which at night prove to be still present and in a certain sense capable of activity. But, since all men and not only neurotic persons have perverse, incestuous, and murderous dreams of this kind, we may infer that those who are normal today have also made the passage through the perversions and the object-investments of the Oedipus complex; and that this is the path of normal development; only that neurotics show in a magnified and exaggerated form what we also find revealed in the dream-analyses of normal people. And this is one of the reasons why we chose the study of dreams to lead up to that of neurotic symptoms.

## TWENTY-SECOND LECTURE

### ASPECTS OF DEVELOPMENT AND REGRESSION. AETIOLOGY

As we have heard, the libido-function goes through an extensive development before it can enter the service of reproduction in the way that is called normal. Now I wish to show you the significance of this fact for the causation of the neuroses.

I think that it will be in agreement with the doctrines of general pathology to assume that such a development involves two dangers; first, that of *inhibition*, and secondly, that of *regression*. That is to say, owing to the general tendency to variation in biological processes it must necessarily happen that not all these preparatory phases will be passed through and completely out-grown with the same degree of success; some parts of the function will be permanently arrested at these early stages, with the result that with the general development there goes a certain amount of inhibited development.

Let us seek analogies to these processes in other fields. When a whole people leaves its

dwellings in order to seek a new country, as often happened in earlier periods of human history, their entire number certainly did not reach the new destination. Apart from losses due to other causes, it must invariably have happened that small groups or bands of the migrating people halted on the way, and settled down in these stopping-places, while the main body went further. Or, to take a nearer comparison, you know that in the higher mammals the seminal glands, which are originally located deep in the abdominal cavity, begin a movement at a certain period of intra-uterine development which brings them almost under the skin of the pelvic extremity. In a number of males it is found that one of this pair of organs has remained in the pelvic cavity, or else that it has taken up a permanent position in the inguinal canal which both of them had to pass through on the journey, or at least that this canal has not closed as it normally should after the passage of the seminal glands through it. When as a young student I was doing my first piece of scientific research under von Brücke, I was working on the origin of the dorsal nerve-roots in the spinal cord of a small fish, still very archaic in form. I found that the nerve-fibres of these roots grew out of large cells in the posterior horn of the grey matter, a condition which is no longer found in other vertebrates. But soon after I discovered that similar nerve-cells were to be found outside the grey matter along the whole length to the so-called spinal ganglion of the posterior roots, from which I concluded that the cells of this ganglion had moved out of the spinal cord along the nerve-roots. Evolutionary development shows this too; in this little fish, however, the whole route of this passage was marked by cells arrested on the way. Closer consideration will soon show you the weak points of these comparisons. Therefore let me simply say that we consider it possible that single portions of every separate sexual impulse may remain in an early stage of development, although at the same time other portions of it may have reached their final goal. You will see from this that we conceive each such impulse as a current continuously flowing from the beginning of life, and that we have divided its flow to some extent artificially into separate successive forward movements. Your impression that these conceptions require further elucidation is correct, but the attempt would lead us too far afield. We will, however, decide at this point to call this *arrest* in a component

impulse at an early stage a **FIXATION** (of the impulse).

The second danger in a development by stages such as this we call **REGRESSION**; it also happens that those portions which have proceeded further may easily revert in a backward direction to these earlier stages. The impulse will find occasion to *regress* in this way when the exercise of its function in a later and more developed form meets with powerful external obstacles, which thus prevent it from attaining the goal of satisfaction. It is a short step to assume that fixation and regression are not independent of each other; the stronger the fixations in the path of development the more easily will the function yield before the external obstacles, by regressing on to those fixations; that is, the less capable of resistance against the external difficulties in its path will the developed function be. If you think of a migrating people who have left large numbers at the stopping-places on their way, you will see that the foremost will naturally fall back upon these positions when they are defeated or when they meet with an enemy too strong for them. And again, the more of their number they leave behind in their progress, the sooner will they be in danger of defeat.

It is important for comprehension of the neuroses that you should keep in mind this relation between fixation and regression. You will thus acquire a secure foothold from which to investigate the causation of the neuroses—their aetiology—which we shall soon consider.

For the present we will keep to the question of regression. After what you have heard about the development of the libido you may anticipate two kinds of regression; a return to the first objects invested with libido, which we know to be incestuous in character, and a return of the whole sexual organization to earlier stages. Both kinds occur in the transference neuroses and play a great part in their mechanism. In particular, the return to the first incestuous objects of the libido is a feature found with quite fatiguing regularity in neurotics. There is much more to be said about the regressions of libido if another group of neuroses, called the narcissistic, is taken into account; but this is not our intention at the moment. These affections yield conclusions about other developmental processes of the libido-function, not yet mentioned, and also show us new types of regression corresponding with them. I think, however, that I had better warn you now above all not to confound

*regression* with *repression* and that I must assist you to clear your minds about the relation between the two processes. *Repression*, as you will remember, is the process by which a mental act capable of becoming conscious (that is, one which belongs to the preconscious system) is made unconscious and forced back into the unconscious system. And we also call it *repression* when the unconscious mental act is not permitted to enter the adjacent preconscious system at all, but is turned back upon the threshold by the censorship. There is, therefore, no connection with sexuality in the concept *repression*; please mark this very carefully. It denotes a purely psychological process; and would be even better described as *topographical*, by which we mean that it has to do with the spatial relationships we assume within the mind, or, if we again abandon these crude aids to the formulation of theory, with the structure of the mental apparatus out of separate psychical systems.

The comparisons just now instituted showed us that hitherto we have not been using the word *regression* in its general sense but in a quite specific one. If you give it its general sense, that of a reversion from a higher to a lower stage of development in general, then repression also ranges itself under regression; for repression can also be described as reversion to an earlier and lower stage in the development of a mental act. Only, in repression this retrogressive direction is not a point of any moment to us; for we also call it repression in a dynamic sense when a mental process is arrested before it leaves the lower stage of the unconscious. Repression is thus a topographic-dynamic conception, while regression is a purely descriptive one. But what we have hitherto called *regression* and considered in its relation to fixation signified exclusively the return of the *libido* to its former halting-places in development, that is, something which is essentially quite different from repression and quite independent of it. Nor can we call regression of the libido a purely psychical process; neither do we know where to localize it in the mental apparatus; for though it may exert the most powerful influence upon mental life, the organic factor in it is nevertheless the most prominent.

Discussions of this sort tend to be rather dry; therefore let us turn to clinical illustrations of them in order to get a more vivid impression of them. You know that the group of the transference neuroses consists principally

of hysteria and the obsessional neurosis. Now in hysteria, a regression of the libido to the primary incestuous sexual objects is without doubt quite regular, but there is little or no regression to an earlier stage of sexual organization. Consequently the principal part in the mechanism of hysteria is played by repression. If I may be allowed to supplement by a construction the certain knowledge of this neurosis acquired up to the present, I might describe the situation as follows: The fusion of the component-impulses under the primacy of the genital zone has been accomplished; but the results of this union meet with resistance from the direction of the preconscious system with which consciousness is connected. The genital organization therefore holds good for the unconscious, but not also for the preconscious, and this rejection on the part of the preconscious results in a picture which has a certain likeness to the state prior to the primacy of the genital zone. It is nevertheless actually quite different. Of the two kinds of regression of the libido, that on to an earlier phase of sexual organization is much the more striking. Since it is absent in hysteria and our whole conception of the neuroses is still far too much dominated by the study of hysteria which came first in point of time, the significance of libidoregression was recognized much later than that of repression. We may be sure that our points of view will undergo still further extensions and alterations when we include consideration of still other neuroses (the narcissistic) in addition to hysteria and the obsessional neurosis.

In the obsessional neurosis, on the other hand, regression of the libido to the antecedent stage of the sadistic-anal organization is the most conspicuous factor and determines the form taken by the symptoms. The impulse to love must then mask itself under the sadistic impulse. The obsessive thought, "I should like to murder you," means (when it has been detached from certain superimposed elements that are not, however, accidental but indispensable to it) nothing else but "I should like to enjoy love of you." When you consider in addition that regression to the primary objects has also set in at the same time, so that this impulse concerns only the nearest and most beloved persons, you can gain some idea of the horror roused in the patient by these obsessive ideas and at the same time how unaccountable they appear to his conscious perception. But repression also has its share, a great one, in the

mechanism of this neurosis, and one which is not easy to expound in a rapid survey such as this. Regression of libido without repression would never give rise to a neurosis, but would result in a perversion. You will see from this that repression is the process which distinguishes the neuroses particularly and by which they are best characterized. Perhaps, however, I may have an opportunity at some time of expounding to you what we know of the mechanism of the perversions, and you will then see that there again nothing proceeds so simply as we should like to imagine in our constructions.

I think that you will be soonest reconciled to this exposition of fixation and regression of the libido if you will regard it as preparatory to a study of the *aetiology* of the neuroses. So far I have only given you one piece of information on this subject, namely, that people fall ill of a neurosis when the possibility of satisfaction for the libido is removed from them—they fall ill in consequence of a *frustration*, as I called it, therefore—and that their symptoms are actually substitutes for the missing satisfaction. This of course does not mean that every frustration in regard to libidinal satisfaction makes everyone who meets with it neurotic, but merely that in all cases of neurosis investigated the factor of frustration was demonstrable. The statement, therefore, cannot be reversed. You will no doubt have understood that this statement was not intended to reveal the whole secret of the aetiology of the neuroses, but that it merely emphasized an important and indispensable condition.

Now in order to consider this proposition further we do not know whether to begin upon the nature of the frustration or the particular character of the person affected by it. The frustration is very rarely a comprehensive and absolute one; in order to have a pathogenic effect it would probably have to strike at the only form of satisfaction which that person desires, the only form of which he is capable. In general, there are very many ways by which it is possible to endure lack of libidinal satisfaction without falling ill. Above all we know of people who are able to take such abstinence upon themselves without injury; they are then not happy, they suffer from unsatisfied longing, but they do not become ill. We therefore have to conclude that the sexual impulse-excitations are exceptionally plastic, if I may use the word. One of them can step in in place of another; if satisfaction of one is denied in

reality, satisfaction of another can offer full recompense. They are related to one another like a network of communicating canals filled with fluid, and this in spite of their subordination to the genital primacy, a condition which is not at all easily reduced to an image. Further, the component-instincts of sexuality, as well as the united sexual impulse which comprises them, show a great capacity to change their object, to exchange it for another—i.e., for one more easily attainable; this capacity for displacement and readiness to accept surrogates must produce a powerful counter-effect to the effect of a frustration. One amongst these processes serving as protection against illness arising from want has reached a particular significance in the development of culture. It consists in the abandonment, on the part of the sexual impulse, of an aim previously found either in the gratification of a component-impulse or in the gratification incidental to reproduction, and the adoption of a new aim—which new aim, though genetically related to the first, can no longer be regarded as sexual, but must be called social in character. We call this process *SUBLIMATION*, by which we subscribe to the general standard which estimates social aims above sexual (ultimately selfish) aims. Incidentally, sublimation is merely a special case of the connections existing between sexual impulses and other, asexual ones. We shall have occasion to discuss this again in another context.

Your impression now will be that we have reduced want of satisfaction to a factor of negligible proportions by the recognition of so many means of enduring it. But no; this is not so: it retains its pathogenic power. The means of dealing with it are not always sufficient. The measure of unsatisfied libido that the average human being can take upon himself is limited. The plasticity and free mobility of the libido is not by any means retained to the full in all of us; and sublimation can never discharge more than a certain proportion of libido, apart from the fact that many people possess the capacity for sublimation only in a slight degree. The most important of these limitations is clearly that referring to the mobility of the libido, since it confines the individual to the attaining of aims and objects which are very few in number. Just remember that incomplete development of the libido leaves behind it very extensive (and sometimes also numerous) libido-fixations upon earlier phases of organization and types of object-choice, mostly

incapable of satisfaction in reality; you will then recognize fixation of libido as the second powerful factor working together with frustration in the causation of illness. We may condense this schematically and say that libido-fixation represents the internal, predisposing factor, while frustration represents the external, accidental factor, in the aetiology of the neuroses.

I will take this opportunity to warn you against taking sides in a quite superfluous dispute. It is a popular habit in scientific matters to seize upon one side of the truth and set it up as the whole truth, and then in favour of that element of truth to dispute all the rest which is equally true. More than one faction has already split off in this way from the psycho-analytic movement; one of them recognizes only the egoistic impulses and denies the sexual; another perceives only the influence of real tasks in life but overlooks that of the individual's past life, and so on. Now here is occasion for another of these antitheses and moot-points: Are the neuroses exogenous or endogenous diseases—the inevitable result of a certain type of constitution or the product of certain injurious (traumatic) events in the person's life? In particular, are they brought about by the fixation of libido and the rest of the sexual constitution, or by the pressure of frustration? This dilemma seems to me about as sensible as another I could point to: Is the child created by the father's act of generation or by the conception in the mother? You will properly reply: Both conditions are alike indispensable. The conditions underlying the neuroses are very similar, if not exactly the same. From the point of view of causation, cases of neurotic illness fall into a *series*, within which the two factors—sexual constitution and events experienced, or, if you wish, fixation of libido and frustration—are represented in such a way that where one of them predominates the other is proportionately less pronounced. At one end of the series stand those extreme cases of whom one can say: "These people would have fallen ill whatever happened, whatever they experienced, however merciful life has been to them, because of their anomalous libido development." At the other end stand cases which call forth the opposite verdict—they would undoubtedly have escaped illness if life had not put such and such burdens upon them. In the intermediate cases in the series, more or less of the disposing factor (the sexual constitution) is combined with less or more

of the injurious impositions of life. Their sexual constitution would not have brought about their neurosis if they had not gone through such and such experiences, and life's vicissitudes would not have worked traumatically upon them if the libido had been otherwise constituted. In this series I can perhaps admit a certain preponderance in the effect of the predisposing factor, but this admission again depends upon where you draw the line in marking the boundaries of nervousness.

I shall now suggest to you that we should call series such as these *complemental series*, and will inform you beforehand that we shall find occasion to establish others of this kind.

The tenacity with which the libido holds to particular channels and particular objects, the *adhesiveness* of the libido, so to say, seems to be an independent factor, varying in individuals, the determining conditions of which are completely unknown to us, but the importance of which in the aetiology of the neuroses we shall certainly no longer underestimate. At the same time we should not overestimate the close relation between the two things. A similar adhesiveness of the libido occurs—from unknown causes—in normal people under numerous conditions, and is found as a decisive factor in those persons who in a certain sense are the extreme opposite of neurotics—namely, perverted persons. It was known before the time of psycho-analysis that in the anamnesis of such persons a very early impression, relating to an abnormal instinct-tendency or object-choice, is frequently discovered, to which the libido of that person henceforth remains attached for life (Binet). It is often hard to say what has enabled this impression to exert such an intense power of attraction upon the libido. I will describe a case of this kind observed by myself. A man to whom the genitals and all the other attractions in a woman now mean nothing can be aroused to irresistible sexual excitation only by a shoe-clad foot of a certain shape; he can remember an event in his sixth year which determined this fixation of libido. He was sitting upon a stool by the side of his governess who was to give him an English lesson. She was a plain, elderly, shrivelled old maid, with watery blue eyes and a snub nose, and on this day she had hurt her foot and had it therefore stretched out on a cushion in a velvet slipper, with the leg itself most decorously concealed. Later on, after a timid attempt at normal sexual activity during puberty,

a thin sinewy foot like that of the governess became his only sexual object; and if still other features in the person reminded him of the type of woman represented by the English governess, the man was helplessly attracted. This fixation of the libido, however, rendered him not neurotic but perverse; he became, as we say, a foot-fetichist. So you see that although an excessive and, in addition, premature fixation of libido is an indispensable condition in the causation of neuroses, the extent of its influence far exceeds the boundaries of the neuroses. This condition by itself is also as little decisive as the frustration mentioned previously.

So the problem of the causation of the neuroses seems to become more complicated. In fact, psycho-analytic investigation acquaints us with yet a new factor, not considered in our aetiological series, and best observed in someone whose previous good health is suddenly disturbed by falling ill of a neurosis. In these people, signs of contradictory and opposed wishes, or, as we say, of *mental conflict*, are regularly found. One side of the personality stands for certain wishes, while another part struggles against them and fends them off. There is no neurosis without such a *CONFLICT*. There might seem to be nothing very special in this; you know that mental life in all of us is perpetually engaged with conflicts that have to be decided. Therefore it would seem that special conditions must be fulfilled before such a conflict can become pathogenic; we may ask what these conditions are, what forces in the mind take part in these pathogenic conflicts, and what relation conflict bears to the other causative factors.

I hope to be able to give you answers to these questions which will be satisfactory although perhaps schematically condensed. Conflict is produced by frustration, in that the libido which lacks satisfaction is urged to seek other paths and other objects. A condition of it then is that these other paths and objects arouse disfavour in one side of the personality, so that a veto ensues, which at first makes the new way of satisfaction impossible. This is the point of departure for the formation of symptoms, which we shall follow up later. The rejected libidinal longings manage to pursue their course by circuitous paths, though not indeed without paying toll to the prohibition in the form of certain disguises and modifications. The circuitous paths are the ways of symptom-formation; the symptoms are the

new and substitutive satisfactions necessitated by the fact of the frustration.

The significance of the mental conflict can be defined in another way, thus: in order to become pathogenic *external* frustration must be supplemented by *internal* frustration. When this is so, the external and the internal frustration relate of course to different paths and different objects; external frustration removes one possibility of satisfaction, internal frustration tries to exclude another possibility, and it is this second possibility which becomes the debatable ground of the conflict. I choose this form of presentation because it contains a certain implication; it implies that the internal impediment arose originally, in primitive phases of human development, out of real external obstacles.

But what are these forces out of which the prohibition against the libidinal longings proceeds, the other parties in the pathogenic conflict? Speaking very broadly, we may say that they are the non-sexual instincts. We include them all under the name *ego-instincts*; analysis of the transference neuroses offers no adequate opportunity for further investigation of them; at most we learn something of them from the resistances opposed to the analysis. The pathogenic conflict is, therefore, one between the ego-instincts and the sexual instincts. In a whole series of cases it looks as though there might also be conflict between various purely sexual impulses; at bottom, however, this is the same thing, because of the two sexual impulses engaged in a conflict one will always be found *consistent with the ego* (ego syntonic) while the other calls forth a protest from the ego. It remains, therefore, a conflict between ego and sexuality.

Over and over again when psycho-analysis has regarded something happening in the mind as an expression of the sexual instincts, indignant protests have been raised to the effect that other instincts and other interests exist in mental life besides the sexual, that one should not derive everything from sexuality, and so on. Well, it is a real pleasure for once to be in agreement with one's opponents. Psycho-analysis has never forgotten that non-sexual instincts also exist; it has been built upon a sharp distinction between sexual instincts and ego-instincts; and in the face of all opposition it has insisted, *not* that they arise from sexuality, but that the neuroses owe their origin to a *conflict* between ego and sexuality. It has no conceiv-

able motive in denying the existence or the significance of the ego-instincts while it investigates the part played by sexual instincts in disease and in life generally. Only, psycho-analysis has been destined to concern itself first and foremost with the sexual instincts, because in the transference neuroses these are the most accessible to investigation, and because it was obliged to study what others had neglected.

It is not any more accurate to say that psycho-analysis has not occupied itself at all with the non-sexual side of the personality. The very distinction between the ego and sexuality has shown us with particular clearness that the ego-instincts also undergo an important development which is neither entirely independent of the development of the libido nor without influence upon the latter. We certainly understand the development of the ego much less well than the development of the libido, because it is only by the study of the narcissistic neuroses that we have just reached some hope of insight into the structure of the ego. Nevertheless, we have already a notable attempt on the part of Ferenczi<sup>1</sup> to reconstruct theoretically the developmental stages of the ego; and there are at least two points at which we have a secure foothold from which to examine this development further. We are not at all disposed to think that the libidinal interests of a human being are from the outset in opposition to the interests of self-preservation; the ego is rather impelled at every stage to attempt to remain in harmony with the corresponding stage of sexual organization and to accommodate itself to that. The succession of the separate phases in the development of the libido probably follows a prescribed course; it is undeniable, however, that this course may be influenced from the direction of the ego. A certain parallelism, a definite correspondence between the phases in the two developments (of the ego and of the libido) may also be assumed; indeed, a disturbance in this correspondence may become a pathogenic factor. More important to us is the question of how the ego behaves when the libido has undergone a powerful fixation at an earlier point in its development. The ego may countenance the fixation and will then be perverse to that extent, or, what is the same thing, infantile; it

<sup>1</sup> Ferenczi, *Contributions to Psycho-Analysis*. English translation by Ernest Jones (1916) chap. viii, p. 181.

may, however, hold itself averse from this attachment of libido, the result of which is that where the libido undergoes a *fixation* there the ego institutes an act of *repression*.

In this way we arrive at the conclusion that the third factor in the aetiology of the neuroses, the susceptibility to conflict, is as much connected with the development of the ego as with the development of the libido; our insight into the causation of the neuroses is thus enlarged. First, there is the most general condition of privation, then the fixation of libido (forcing it into particular channels), and thirdly, the *susceptibility to conflict* produced by the development of the ego having repudiated libidinal excitations of that particular kind. The thing is, therefore, not so very obscure and intricate as you probably thought it during the course of my exposition. To be sure, though, after all, we have not done with it yet; there is still something new to add and something we already know to dissect further.

In order to demonstrate the effect of the development of the ego upon the tendency to conflict and therewith upon the causation of the neurosis, I will quote an example which, although entirely imaginary, is not at all improbable in any respect. I will give it the title of Nestroy's farce: *On the Ground-Floor and in the Mansion*. Suppose that a caretaker is living on the ground-floor of a house, while the owner, a rich and well-connected man, lives above. They both have children, and we will assume that the owner's little girl is permitted to play freely without supervision with the child of lower social standing. It may then very easily happen that their games become "naughty," that is, take on a sexual character: that they play "father and mother," watch each other in the performance of intimate acts, and stimulate each other's genital parts. The caretaker's daughter may have played the temptress in this, since in spite of her five or six years she has been able to learn a great deal about sexual matters. These occurrences, even though they are only kept up for a short period, will be enough to rouse certain sexual excitations in both children which will come to expression in the practice of masturbation for a few years, after the games have been discontinued. There is common ground so far, but the final result will be very different in the two children. The caretaker's daughter will continue masturbation, perhaps up to the onset of menstruation, and then give it up without difficulty; a few

years later will find a lover, perhaps bear a child; choose this or that path in life, perhaps become a popular actress and end as an aristocrat. Probably her career will turn out less brilliantly, but in any case she will be unharmed by the premature sexual activity, free from neurosis, and able to live her life. Very different is the result in the other child. She will very soon, while yet a child, acquire a sense of having done wrong; after a fairly short time she will give up the masturbatory satisfaction, though perhaps only with a tremendous struggle, but will nevertheless retain an inner feeling of subdued depression. When later on as a young girl she comes to learn something of sexual intercourse, she will turn from it with inexplicable horror and wish to remain ignorant. Probably she will then again suffer a fresh irresistible impulse to masturbation about which she will not dare to unburden herself to anyone. When the time comes for a man to choose her as a wife the neurosis will break out and cheat her out of marriage and the joy of life. If analysis makes it possible to obtain an insight into this neurosis, it will be found that this well-brought-up, intelligent and idealistic girl has completely repressed her sexual desires; but that they are, unconsciously, attached to the few little experiences she had with the childish play-mate.

The differences which ensue in these two destinies in spite of the common experiences undergone, arise because in one girl the ego has sustained a development absent in the other. To the caretaker's daughter sexual activity seemed as natural and harmless in later years as in childhood. The gentleman's daughter had been "well brought-up" and had adopted the standards of her education. Thus stimulated, her ego had formed ideals of womanly purity and absence of desire that were incompatible with sexual acts; her intellectual training had caused her to depreciate the feminine rôle for which she is intended. This higher moral and intellectual development in her ego has brought her into conflict with the claims of her sexuality.

I will explore one more aspect of the development of the libido today, both because it leads out upon certain wide prospects, and also because it is well suited to justify the sharp, and not immediately obvious, line of demarcation we are wont to draw between go-instincts and sexual instincts. In considering the two developments undergone by the ego and by the

libido we must emphasize an aspect which hitherto has received little attention. Both of them are at bottom inheritances, abbreviated repetitions of the evolution undergone by the whole human race through long-drawn out periods and from prehistoric ages. In the development of the libido this phylogenetic origin is readily apparent, I should suppose. Think how in one class of animals the genital apparatus is in closest relation with the mouth, in another it is indistinguishable from the excretory mechanism, in another it is part of the organs of motility; you will find a delightful description of these facts in W. Bölsche's valuable book. One sees in animals all the various perversions, ingrained, so to speak, in the form taken by their sexual organizations. Now the phylogenetic aspect is to some extent obscured in man by the circumstances that what is fundamentally inherited is nevertheless individually acquired anew, probably because the same conditions that originally induced its acquisition still prevail and exert their influence upon each individual. I would say, where they originally created a new response they now stimulate a predisposition. Apart from this, it is unquestionable that the course of the prescribed development in each individual can be disturbed and altered by current impressions from without. But the power which has enforced this development upon mankind, and still today maintains its pressure in the same course, is known to us; it is, again, the frustration exacted by reality; or, if we give it its great real name, it is *necessity*, the struggle for life, *ἀνάγκη*. Necessity has been a severe taskmistress, and she has taught us a great deal. Neurotics are those of her children upon whom this severity has had evil effects, but that risk is inevitable in any education. Incidentally, this view of the struggle for existence as the motive force in evolution need not detract from the significance of *inner evolutionary tendencies*, if such are found to exist.

Now it is very noteworthy that sexual instincts and self-preservative instincts do not behave alike when confronted with the necessity of real life. The self-preservative instincts and all that hangs together with them are more easily moulded; they learn early to conform to necessity and to adapt their development according to the mandates of reality. This is comprehensible, for they cannot obtain the objects they require by any other means, and without these objects the individual must

perish. The sexual instincts are less easily moulded; for in the beginning they do not know any lack of objects. Since they are connected parasitically, as it were, with the other physical functions and at the same time can be auto-erotically gratified on their own body, they are at first isolated from the educative influence of real necessity; and in most people they retain throughout life, in some respect or other, this character of obstinacy and inaccessibility to influence which we call *unreasonableness*. Moreover, the educability of a young person as a rule comes to an end when sexual desire breaks out in its final strength. Educators know this and act accordingly; but perhaps they will yet allow themselves to be influenced by the results of psycho-analysis so that they will transfer the main emphasis in education to the earliest years of childhood, from the suckling period onward. The little human being is frequently a finished product in his fourth or fifth year, and only gradually reveals in later years what lies buried in him.

To appreciate the full significance of this difference between the two groups of instincts we must digress some distance, and include one of those aspects which deserve to be called *economic*; we enter here upon one of the most important, but unfortunately one of the most obscure, territories of psycho-analysis. We may put the question whether a main purpose is discernible in the operation of the mental apparatus; and our first approach to an answer is that this purpose is directed to the attainment of pleasure. It seems that our entire psychical activity is bent upon *procuring pleasure* and *avoiding pain*, that it is automatically regulated by the PLEASURE-PRINCIPLE. Now of all things in the world we should like to know what are the conditions giving rise to pleasure and pain, but that is just where we fall short. We may only venture to say that pleasure is *in some way* connected with lessening, lowering, or extinguishing the amount of stimulation present in the mental apparatus; and that pain involves a heightening of the latter. Consideration of the most intense pleasure of which man is capable, the pleasure in the performance of the sexual act, leaves little doubt upon this point. Since pleasurable processes of this kind are bound up with the distribution of quantities of mental excitation and energy, we term considerations of this kind *economic* ones. It appears that we can describe the tasks and performances of the mental apparatus in another

way and more generally than by emphasizing the attainment of pleasure. We can say that the mental apparatus serves the purpose of mastering and discharging the masses of supervening stimuli, the quantities of energy. It is quite plain that the sexual instincts pursue the aim of gratification from the beginning to the end of their development; throughout they keep up this primary function without alteration. At first the other group, the ego-instincts, do the same; but under the influence of necessity, their mistress, they soon learn to replace the pleasure-principle by a modification of it. The task of avoiding pain becomes for them almost equal in importance to that of gaining pleasure; the ego learns that it must inevitably go without immediate satisfaction, postpone gratification, learn to endure a degree of pain, and altogether renounce certain sources of pleasure. Thus trained, the ego becomes "reasonable," is no longer controlled by the pleasure-principle, but follows the REALITY-PRINCIPLE, which at bottom also seeks pleasure—although a delayed and diminished pleasure, one which is assured by its realization of fact, its relation to reality.

The transition from the pleasure-principle to the reality principle is one of the most important advances in the development of the ego. We already know that the sexual instincts follow late and unwillingly through this stage; presently we shall learn what the consequences are to man that his sexuality is satisfied with such a slight hold upon external reality. And now in conclusion one more observation relevant in this connection. If the ego in mankind has its evolution like libido, you will not be surprised to hear that there exist *ego-regressions* too, and will wish to know the part this reversion of the ego to earlier stages in development can play in neurotic disease.

## TWENTY-THIRD LECTURE

### THE PATHS OF SYMPTOM-FORMATION

IN the eyes of the general public, the symptoms are the essence of a disease, and to them a cure means the removal of the symptoms. In medicine, however, we find it important to differentiate between symptoms and disease, and state that the disappearance of the symptoms is by no means the same as the cure of the disease. The only tangible element of the disease that remains after the removal of the symptoms, however, is the capacity to form new

symptoms. Therefore for the moment let us adopt the lay point of view and regard a knowledge of the foundation of the symptoms as equivalent to understanding the disease.

The symptoms—of course we are here dealing with mental (or psychogenic) symptoms, and mental disease—are activities which are detrimental, or at least useless, to life as a whole; the person concerned frequently complains of them as obnoxious to him or they involve distress and suffering for him. The principal injury they inflict lies in the expense of mental energy they entail and, besides this, in the energy needed to combat them. Where the symptoms are extensively developed, these two kinds of effort may exact such a price that the person suffers a very serious impoverishment in available mental energy, which consequently disables him for all the important tasks of life. This result depends principally upon the amount of energy taken up in this way, therefore you will see that *illness* is essentially a practical conception. But if you look at the matter from a theoretical point of view and ignore this question of degree you can very well say that we are all ill, i.e., neurotic; for the conditions required for symptom-formation are demonstrable also in normal persons.

Of neurotic symptoms we already know that they are the result of a conflict arising when a new form of satisfaction of libido is sought. The two powers which have entered into opposition meet together again in the symptom and become reconciled by means of the *compromise* contained in symptom-formation. That is why the symptom is capable of such resistance; it is sustained from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido, frustrated by reality and now forced to seek other paths to satisfaction. If reality remains inexorable, even when the libido is prepared to take another object in place of that denied, the libido will then finally be compelled to resort to regression, and to seek satisfaction in one of the organizations it had already surmounted or in one of the objects it had relinquished earlier. The libido is drawn into the path of regression by the fixations it has left behind it at these places in its development.

Now the path of perversion branches off sharply from that of neurosis. If these regressions do not call forth a prohibition on the part of the ego, no neurosis results; the libido succeeds in obtaining a real, although not a

normal satisfaction. But if the ego, which controls not merely consciousness but also the approaches to motor innervation and hence the realization in actuality of mental impulses, is not in agreement with these regressions, conflict ensues. The libido is blocked, as it were, and must seek an escape by which it can find an outlet for its cathexis (charge of energy) in conformity with the demands of the pleasure-principle: it must elude, eschew the ego. The fixations upon the path of development now regressively traversed—fixations against which the ego had previously guarded itself by repressions—offer just such an escape. In streaming backward and re-*cathecting* these repressed positions, the libido withdraws itself from the ego and its laws; but it also abandons all the training acquired under the influence of the ego. It was docile as long as satisfaction was in sight; under the double pressure of external and internal frustration it becomes intractable and harks back to former happier days. That is its essential unchangeable character. The ideas to which the libido now transfers its cathexis belong to the unconscious system and are subject to the special processes characteristic of that system—namely, condensation and displacement. Conditions are thus set up which correspond exactly with those of dream formation. Just as the latent dream, first formed in the unconscious out of the thoughts proper, and constituting the fulfilment of an unconscious wish phantasy, meets with some (pre)conscious activity which exerts a censorship upon it and permits, according to its verdict, the formation of a compromise in the manifest dream, so the ideas to which the libido is attached (libido-representatives) in the unconscious have still to contend with the power of the preconscious ego. The opposition against it in the ego follows it as an anti-cathexis (counter-charge) and forces it to adopt a form of expression by which the opposing forces can at the same time express themselves. In this way the symptom then comes into being, as a derivative, distorted in manifold ways, of the unconscious libidinal wish-fulfilment, as a cleverly chosen ambiguity with two completely contradictory significations. In this last point alone is there a difference between dream-formation and symptom-formation; for the preconscious purpose in dream-formation is merely to preserve sleep and to allow nothing that would disturb it to penetrate consciousness; it does not insist upon confronting the unconscious wish-impulse with a sharp prohibiting "No, on the contrary." It

can be more tolerant because a sleeping person is in a less dangerous position; the condition of sleep is enough in itself to prevent the wish from being realized in actuality.

You see that this escape of the libido under the conditions of conflict is rendered possible by the existence of fixations. The regressive cathexis (with libido) of these fixations leads to a circumventing of the repressions and to a discharge—or a satisfaction—of the libido, in which the conditions of a compromise have nevertheless to be maintained. By this detour through the unconscious and the old fixations the libido finally succeeds in attaining to a real satisfaction, though the satisfaction is certainly of an exceedingly restricted kind and hardly recognizable as such. Let me add two remarks on this outcome. First, will you notice how closely connected the libido and the unconscious, on the one hand, and the ego, consciousness, and reality, on the other, show themselves to be, although there were no such connections between them originally; and secondly, let me tell you that all I have said and have still to say on this point concerns the neurosis of hysteria only.

Where does the libido find the fixations it needs in order to break through the repressions? In the activities and experiences of infantile sexuality, in the component-tendencies and the objects of childhood which have been relinquished and abandoned. It is to them, therefore, that the libido turns back. The significance of childhood is a double one; on the one hand the congenitally determined instinct-dispositions are first shown at that time, and secondly, other instincts are then first awakened and activated by external influences and accidental events experienced. In my opinion we are quite justified in laying down this dichotomy. That the innate predisposition comes to expression will certainly not be disputed; but analytic observation even requires us to assume that purely accidental experiences in childhood are capable of inducing fixations of libido. Nor do I see any theoretical difficulty in this. Constitutional predispositions are undoubtedly the after-effects of the experiences of an earlier ancestry; they also have been at one time acquired; without such acquired characters there would be no heredity. And is it conceivable that the acquisition of characters which will be transmitted further should suddenly cease in the generation which is being observed today? The importance of the infantile experiences should not, however, be entirely overlooked, as so often

happens, in favour of ancestral experiences or of experiences in adult life; but on the contrary they should be particularly appreciated. They are all the more pregnant with consequences because they occur at a time of uncompleted development, and for this very reason are likely to have a traumatic effect. The work done by Roux and others on the mechanism of development has shown that a needle pricked into an embryonic cell-mass undergoing division results in serious disturbances of the development; the same injury to a larva or a full-grown animal would be innocuous.

The libido-fixation of an adult, which we have referred to as representing the constitutional factor in the aetiology of the neuroses, may therefore now be divided into two further elements: the inherited predisposition and the predisposition acquired in early childhood. Since a schematic mode of presentation is always acceptable to a student, let us formulate these relations as follows:

The hereditary sexual constitution provides a great variety of predispositions, according as this or that component-impulse, alone or in combination with others, is specially strongly accentuated. Together with the infantile experiences the sexual constitution forms another *complementary series*, quite similar to that already described as being formed out of the predisposition and accidental experiences of an adult. In each series similar extreme cases are met with, and also similar degrees and relationships between the factors concerned. It would be appropriate at this point to consider whether the more striking of the two kinds of libido-regression (that which reverts to earlier stages of sexual organization) is not predominantly conditioned by the hereditary constitutional factor; but the answer to this question is best postponed until a wider range of forms of neurotic disease can be considered.

Now let us devote attention to the fact that analytic investigation shows the libido of neu-

rotics to be attached to their infantile sexual experiences. In this light these experiences seem to be of enormous importance in the lives and illnesses of mankind. This importance remains undiminished in so far as the therapeutic work of analysis is concerned; but regarded from another point of view it is easy to see that there is a danger of a misunderstanding here, one which might delude us into regarding life too exclusively from the angle of the situation in neurotics. The importance of the infantile experiences is after all diminished by the reflection that the libido reverts regressively to them *after* it has been driven from its later positions. This would lead us towards the opposite conclusion, that the libido-experiences had no importance at the time of their occurrence, but only acquired it later by regression. You will remember that we discussed a similar alternative before, in dealing with the Oedipus complex.

To decide this point is again not difficult. The statement is undoubtedly correct that regression greatly augments the cathexis of the infantile experiences with libido—and with that their pathogenic significance; but it would be misleading to allow this alone to become decisive. Other considerations must be taken into account as well. To begin with, observation shows in a manner excluding all doubt that infantile experiences have their own importance which is demonstrated already during childhood. There are, indeed, neuroses in children too; in their neuroses the factor of displacement backwards in time is necessarily much diminished, or quite absent, the outbreak of illness following immediately upon a traumatic experience. The study of infantile neuroses guards us from many risks of misunderstanding the neuroses of adults, just as children's dreams gave us the key to comprehension of the dreams of adults. Neurosis in children is very common, far more common than is usually supposed. It is often overlooked, regarded as a manifestation of bad behaviour or naughtiness, and often subdued by the authorities in the nursery; but in retrospect it is always easily recognizable. It appears most often in the form of anxiety-hysteria; we shall learn what that means on another occasion. When a neurosis breaks out in later life analysis invariably reveals it to be a direct continuation of that infantile neurosis, which had perhaps been expressed in a veiled and incipient form only; as has been said, however, there are cases in which the childish nervousness is carried on

into lifelong illness without a break. In a few instances we have been able to analyse a child actually in a condition of neurosis; far more often we have had to be satisfied with the retrospective insight into a childhood-neurosis that can be gained through someone who has fallen ill in mature years, a situation in which due corrections and precautions must not be neglected.

In the second place, it would certainly be inexplicable that the libido should regress so regularly to the time of childhood if there had been nothing there which could exert an attraction upon it. The fixation upon certain stages of development, which we assume, only has meaning if we regard it as attaching to itself a definite amount of libidinal energy. Finally, I may point out that a complementary relationship exists here between the intensity and pathogenic importance of the *infantile* and of the *later* experiences, again a similar relationship to that found in the other two series we have already studied. There are cases in which the whole accent of causation falls on the sexual experiences in childhood; cases in which these impressions undoubtedly had a traumatic effect, nothing more than the average sexual constitution and its immaturity being required to supplement them. Then there are others in which all the accent lies on the later conflicts, and the analytic emphasis upon the childhood-impressions seems to be the effect of regression alone. There exist, therefore, the two extremes—*inhibited development* and *regression*—and between them every degree of combination of the two factors.

This state of things has a certain interest for those looking to pedagogy for the prevention of neuroses by early intervention in the matter of the child's sexual development. As long as attention is directed mainly to the infantile sexual experiences one would think everything in the way of prophylaxis of later neurosis could be done by ensuring that this development should be retarded and the child secured against this kind of experience. But we know that the conditions causing neurosis are more complicated than this and that they cannot be influenced in a general way by attending to one factor only. Strict supervision in childhood loses value because it is helpless against the constitutional factor; more than this, it is less easy to carry out than specialists in education imagine; and it entails two new risks, which are not to be lightly disregarded. It may accomplish too much; in that it favours an exag-

gerated degree of sexual repression which is harmful in its effects, and it sends the child into life without power to resist the urgent demands of his sexuality that must be expected at puberty. It therefore remains most doubtful how far prophylaxis in childhood can go with advantage, and whether a changed attitude to actuality would not constitute a better point of departure for attempts to forestall the neuroses.

Let us return to consideration of the symptoms. They yield a satisfaction in place of one lacking in reality; they achieve this by means of a regression of the libido to a previous time of life, with which regression is indissolubly connected, a reversion to earlier phases in the object-choice or in the organization. We learned some time ago that the neurotic is in some way *tied* to a period in his past life; we know now that this period in the past is one in which his libido could attain satisfaction, one in which he was happy. He looks back on his life-story, seeking some such period, and goes on seeking it, even if he must go back to the time when he was a suckling infant to find it according to his recollection or his imagination of it under later influences. In some way the symptom reproduces that early infantile way of satisfaction, disguised though it is by censorship implicit in the conflict, converted as it usually is into a sensation of suffering, and mingled with elements drawn from the experiences leading up to the outbreak of the illness. The kind of satisfaction which the symptom brings has much about it which estranges us, quite apart from the fact that the person concerned is unaware of the satisfaction and perceives this that we call satisfaction much more as suffering, and complains of it. This transformation belongs to the mental conflict, by the pressure of which the symptom had to be formed; what was at one time a satisfaction must today arouse resistance or horror in him. We are familiar with a simple but instructive instance of such a change of feeling: the same child that sucked milk with voracity from its mother's breast often shows, some years later, a strong dislike of milk which can with difficulty be overcome by training; this dislike is intensified to the point of horror if the milk or any other kind of liquid containing it has a skin formed upon it. It is possible that the skin calls up reverberations of a memory of the mother's breast, once so ardently desired; it is true that the traumatic experience of weaning has intervened meanwhile.

There is still something else which makes the

symptoms seem remarkable and inexplicable as a means of libidinal satisfaction. They so entirely fail to remind us of all that we are accustomed normally to connect with satisfaction. They are mostly quite independent of an object and thus have given up a relation to external reality. We understand this as a consequence of the rejection of the reality-principle and the return to the pleasure-principle; it is also, however, a return to a kind of amplified auto-erotism, the kind which offered the sexual instinct its first gratifications. In the place of effecting a change in the outer world they set up a change in the body itself; that is, an internal action instead of an external one, an adaptation instead of an activity—from a phylogenetic point of view again a very significant regression. We shall understand this better when we consider it in connection with a new factor yet to be learnt from among those which analytic research has yielded in regard to symptom-formation. Further, we remember that in symptom-formation the same unconscious processes are at work as in dream-formation, namely, condensation and displacement. Like the dream, the symptom represents something as fulfilled, a satisfaction infantile in character; but by the utmost condensation this satisfaction can be compressed into a single sensation or innervation, or by farthest displacement can be whittled away to a tiny detail out of the entire libidinal complex. It is no wonder that we often find it difficult to recognize in the symptom the libidinal satisfaction which we suspect and can always verify in it.

I have indicated that we have still to learn of a new element; it is really something most surprising and bewildering. You know that from analysis of symptoms we arrive at a knowledge of the infantile experiences to which the libido is fixated and out of which the symptoms are made up. Now the astonishing thing is that these scenes of infancy are not always true. Indeed, in the majority of cases they are untrue, and in some cases they are in direct opposition to historical truth. You will see that this discovery is more likely than any other to discredit either the analysis which leads to such results, or the patient, upon whose testimony the analysis and comprehension of the neuroses as a whole is built up. There is besides this still something utterly bewildering about it. If the infantile experiences brought to light by the analysis were in every case real we should have the feeling that we were on firm ground; if they were invariably falsified and found to be

inventions and phantasies of the patient's we should have to forsake this insecure foothold and save ourselves some other way. But it is neither one thing nor the other; for what we find is that the childhood-experiences reconstructed or recollected in analysis are on some occasions undeniably false, while others are just as certainly quite true, and that in most cases truth and falsehood are mixed up. So the symptoms are thus at one minute reproductions of experiences which actually took place and which one can credit with an influence on the fixation of the libido; and at the next a reproduction of phantasies of the patient's to which, of course, it is difficult to ascribe any aetiological significance. It is hard to find one's way here. We may perhaps find our first clue in a discovery of a similar kind, namely, that the meagre childish recollections which people have always, long before analysis, consciously preserved can be falsified in the same way, or at least can contain a generous admixture of truth and falsehood; evidence of error in them is nearly always plainly visible, and so we have at least the reassurance that not the analysis, but the patient in some way, must bear the responsibility for this unexpected disappointment.

After a little reflection we can easily understand what it is that is so bewildering in this matter. It is the depreciation of reality, the neglect of the difference between reality and phantasy; we are tempted to be offended with the patient for taking up our time with invented stories. According to our way of thinking heaven and earth are not farther apart than fiction from reality, and we value the two quite differently. The patient himself, incidentally, takes the same attitude when he is thinking normally. When he brings forward the material that leads us to the wished-for situations (which underlie the symptoms and are formed upon the childhood experiences), we are certainly in doubt at first whether we have to deal with reality or with phantasies. Decision on this point becomes possible later by means of certain indications, and we are then confronted with the task of making this result known to the patient. This is never accomplished without difficulty. If we tell him at the outset that he is now about to bring to light the phantasies in which he has shrouded the history of his childhood, just as every race weaves myths about its forgotten early history, we observe to our dissatisfaction that his interest in pursuing the subject further suddenly declines—he also wishes to find out facts and despises what is

called *imagination*. But if we leave him to believe until this part of the work has been carried through that we are investigating the real events of his early years, we run the risk of being charged with the mistake later and of being laughed at for our apparent gullibility. It takes him a long time to understand the proposal that phantasy and reality are to be treated alike and that it is to begin with of no account whether the childhood-experiences under consideration belong to the one class or to the other. And yet this is obviously the only correct attitude towards these products of his mind. They have indeed also a kind of reality; it is a fact that the patient has created these phantasies, and for the neurosis this fact is hardly less important than the other—if he had really experienced what they contain. In contrast to *material* reality these phantasies possess *psychical* reality, and we gradually come to understand that *in the world of neurosis PSYCHICAL REALITY is the determining factor*.

Among the occurrences which continually recur in the story of a neurotic's childhood, and seem hardly ever absent, are some of particular significance which I therefore consider worthy of special attention. As models of this type I will enumerate: observation of parental intercourse, seduction by an adult, and the threat of castration. It would be a great mistake to suppose that they never occur in reality; on the contrary, they are often confirmed beyond doubt by the testimony of older relatives. Thus, for example, it is not at all uncommon for a little boy, who is beginning to play with his penis and has not yet learnt that he must conceal such activities, to be threatened by parents or nurses that his member or his offending hand will be cut off. Parents will often admit the fact on being questioned, since they imagine that such intimidation was the right course to take; many people have a clear conscious recollection of this threat, especially if it took place in later childhood. If the mother or some other woman makes the threat she usually shifts the execution of it to someone else, indicating that the father or the doctor will perform the deed. In the famous *Struwwelpeter* by the Frankfort physician for children, Hoffmann, which owes its popularity precisely to his understanding of the sexual and other complexes of children, you will find the castration idea modified and replaced by cutting off the thumbs as a punishment for stubborn sucking of them. It is, however, highly improbable that the threat of castration has been delivered as

often as would appear from the analysis of a neurotic. We are content to understand that the child concocts a threat of this kind out of its knowledge that auto-erotic satisfactions are forbidden, on the basis of hints and allusions, and influenced by the impression received on discovering the female genital organ. Similarly, it is not at all impossible that a small child, credited as he is with no understanding and no memory, may be witness of the sexual act on the part of his parents or other adults in other families besides those of the proletariat; and there is reason to think that the child can *subsequently* understand the impression received and react to it. But when this act of intercourse is described with minute details which can hardly have been observed, or when it appears, as it most frequently does, to have been performed from behind, *more feriorum*,<sup>1</sup> there can be little doubt that this phantasy has grown out of the observation of copulating animals (dogs) and that its motive force lies in the unsatisfied skoptophilia (gazing-impulse) of the child during puberty. The greatest feat achieved by this kind of phantasy is that of observing parental intercourse while still unborn in the mother's womb.

The phantasy of seduction has special interest, because only too often it is no phantasy but a real remembrance; fortunately, however, it is still not as often real as it seemed at first from the results of analysis. Seduction by children of the same age or older is more frequent than by adults; and when girls who bring forward this event in the story of their childhood fairly regularly introduce the father as the seducer, neither the phantastic character of this accusation nor the motive actuating it can be doubted. When no seduction has occurred, the phantasy is usually employed to cover the childhood period of auto-erotic sexual activity; the child evades feelings of shame about onanism by retrospectively attributing in phantasy a desired object to the earliest period. Do not suppose, however, that sexual misuse of children by the nearest male relatives is entirely derived from the world of phantasy; most analysts will have treated cases in which such occurrences actually took place and could be established beyond doubt; only even then they belonged to later years of childhood and had been transposed to an earlier time.

All this seems to lead to but one impression, that childhood experiences of this kind are in some way necessarily required by the neurosis,

<sup>1</sup> In the manner of animals.—ED.

that they belong to its unvarying inventory. If they can be found in real events, well and good; but if reality has not supplied them they will be evolved out of hints and elaborated by phantasy. The effect is the same, and even today we have not succeeded in tracing any variation in the results according as phantasy or reality plays the greater part in these experiences. Here again is one of those complementary series so often referred to already; it is certainly the strangest of all those we have encountered. Whence comes the necessity for these phantasies, and the material for them? There can be no doubt about the instinctual sources; but how is it to be explained that the same phantasies are always formed with the same content? I have an answer to this which I know will seem to you very daring. I believe that these *primal phantasies* (as I should like to name these, and certainly some others also) are a phylogenetic possession. In them the individual, wherever his own experience has become insufficient, stretches out beyond it to the experience of past ages. It seems to me quite possible that all that today is narrated in analysis in the form of phantasy, seduction in childhood, stimulation of sexual excitement upon observation of parental coitus, the threat of castration—or rather, castration itself—was in prehistoric periods of the human family a reality; and that the child in its phantasy simply fills out the gaps in its true individual experiences with true prehistoric experiences. We have again and again been led to suspect that more knowledge of the primordial forms of human development is stored up for us in the psychology of the neuroses than in any other field we may explore.

Now these things that we have been discussing require us to consider more closely the origin and meaning of that mental activity called *phantasy-making*. In general, as you know, it enjoys high esteem, although its place in mental life has not been clearly understood. I can tell you as much as this about it. You know that the ego in man is gradually trained by the influence of external necessity to appreciate reality and to pursue the reality-principle, and that in so doing it must renounce temporarily or permanently various of the objects and aims—not only sexual—of its desire for pleasure. But renunciation of pleasure has always been very hard to man; he cannot accomplish it without some kind of compensation. Accordingly he has evolved for himself a mental activity in which all these relinquished

sources of pleasure and abandoned paths of gratification are permitted to continue their existence, a form of existence in which they are free from the demands of reality and from what we call the exercise of *testing reality*. Every longing is soon transformed into the idea of its fulfilment; there is no doubt that dwelling upon a wish fulfilment in phantasy brings satisfaction, although the knowledge that it is not reality remains thereby unobscured. In phantasy, therefore, man can continue to enjoy a freedom from the grip of the external world, one which he has long relinquished in actuality. He has contrived to be alternately a pleasure-seeking animal and a reasonable being; for the meagre satisfaction that he can extract from reality leaves him starving. "There is no doing without accessory constructions," said Fontane. The creation of the mental domain of phantasy has a complete counterpart in the establishment of *reservations* and *nature-parks* in places where the inroads of agriculture, traffic, or industry threaten to change the original face of the earth rapidly into something unrecognizable. The *reservation* is to maintain the old condition of things which has been regretfully sacrificed to necessity everywhere else; there everything may grow and spread as it pleases, including what is useless and even what is harmful. The mental realm of phantasy is also such a reservation reclaimed from the encroachments of the reality-principle.

The best-known productions of phantasy have already been met by us; they are called *day-dreams*, and are imaginary gratifications of ambitious, grandiose, erotic wishes, dilating the more extravagantly the more reality admonishes humility and patience. In them is shown unmistakably the essence of imaginary happiness, the return of gratification to a condition in which it is independent of reality's sanction. We know that these day-dreams are the kernels and models of night-dreams; fundamentally the night-dream is nothing but a day-dream distorted by the nocturnal form of mental activity and made possible by the nocturnal freedom of instinctual excitations. We are already familiar with the idea that a day-dream is not necessarily conscious, that unconscious day-dreams also exist; such unconscious day-dreams are therefore just as much the source of night-dreams as of neurotic symptoms.

The significance of phantasy for symptom-formation will become clear to you in what follows. We said that, under frustration, the libido regressively invests the positions it had

left but to which nevertheless some portions of its energy had remained attached. We shall not retract or correct this statement, but we shall have to interpolate a connecting-link in it. How does the libido find its way back to these fixation-points? Now the objects and channels which have been forsaken by the libido have not been forsaken in every sense; they, or their derivatives, are still retained to some degree of intensity in the conceptions of phantasy. The libido has only to withdraw on to the phantasies in order to find the way open to it back to all the repressed fixations. These phantasies had enjoyed a certain sort of toleration; no conflict between them and the ego had developed, however sharp an opposition there was between them, as long as a certain condition was preserved—a condition of a *quantitative* nature, now disturbed by the return of the libidostream on to the phantasies. By this accession, the cathexis of the phantasies with energy becomes so much augmented that they become assertive and begin to press towards realization; then, however, conflict between them and the ego becomes unavoidable. Although previously they were preconscious or conscious, now they are subject to repression from the side of the ego and are exposed to the attraction exerted from the side of the unconscious. The libido travels from the phantasies, now unconscious, to their sources in the unconscious—back to its own fixation-points again.

The return of the libido on to phantasy is an intermediate step on the way to symptom-formation which well deserves a special designation. C. G. Jung has coined for it the very appropriate name of *INTROVERSION*, but inappropriately he uses it also to describe other things. We will adhere to the position that *introversion* describes the deflection of the libido away from the possibilities of real satisfaction and its excessive accumulation upon phantasies previously tolerated as harmless. An introverted person is not yet neurotic, but he is in an unstable condition; the next disturbance of the shifting forces will cause symptoms to develop, unless he can yet find other outlets for his pent-up libido. The unreal character of neurotic satisfaction and the disregard of the difference between phantasy and reality are already determined by the arrest at this stage of introversion.

You will doubtless have noticed that in these last remarks I have introduced a new factor into the concatenation of the aetiological chain—namely, the *quantity*, the magnitude of the

energies concerned; we must always take this factor into account as well. A purely qualitative analysis of the aetiological conditions does not suffice; or, to put it in another way, a purely *dynamic* conception of these processes is insufficient, the *economic* aspect is also required. We have to realize that the conflict between the two forces in opposition does not break out until a certain intensity in the degree of investment is reached, even though the substantive conditions have long been in existence. In the same way, the pathogenic significance of the constitutional factor is determined by the preponderance of one of the component-instincts in *excess* over another in the disposition; it is even possible to conceive disposition as qualitatively the same in all men and only differentiated by this quantitative factor. No less important is this quantitative factor for the capacity to withstand neurotic illness; it depends upon the *amount* of undischarged libido that a person can hold freely suspended, and upon *how large* a portion of it he can deflect from the sexual to a nonsexual goal in sublimation. The final aim of mental activity, which can be qualitatively described as a striving towards pleasure and avoidance of pain, is represented economically in the task of mastering the distribution of the quantities of excitation (stimulus-masses) present in the mental apparatus, and in preventing the accumulation of them which gives rise to pain.

I set out to tell you as much as this about symptom-formation in the neuroses. Yes, but I must not neglect to mention once more that everything said today relates only to symptom-formation in hysteria. Even the obsessional neurosis shows great differences, although the essentials are the same. The *counter-charges* from the ego against the demands made by instincts for satisfaction, mentioned already in connection with hysteria, are more strongly marked in the obsessional neurosis and govern the clinical picture in the form of what we call *reaction-formations*. Similar and more extensive deviations still are found in the other neuroses, in which field researches into the mechanisms of symptom-formation are not yet complete in any direction.

Before you leave today I should like to direct your attention for a moment to a side of phantasy-life of very general interest. There is, in fact, a path from phantasy back again to reality, and that is—art. The artist has also an introverted disposition and has not far to go to become neurotic. He is one who is urged

on by instinctual needs which are too clamorous; he longs to attain to honour, power, riches, fame, and the love of women; but he lacks the means of achieving these gratifications. So, like any other with an unsatisfied longing, he turns away from reality and transfers all his interest, and all his libido too, on to the creation of his wishes in the life of phantasy, from which the way might readily lead to neurosis. There must be many factors in combination to prevent this becoming the whole outcome of his development; it is well known how often artists in particular suffer from partial inhibition of their capacities through neurosis. Probably their constitution is endowed with a powerful capacity for sublimation and with a certain flexibility in the repressions determining the conflict. But the way back to reality is found by the artist thus: He is not the only one who has a life of phantasy; the intermediate world of phantasy is sanctioned by general human consent, and every hungry soul looks to it for comfort and consolation. But to those who are not artists the gratification that can be drawn from the springs of phantasy is very limited; their inexorable repressions prevent the enjoyment of all but the meagre day-dreams which can become conscious. A true artist has more at his disposal. First of all he understands how to elaborate his day-dreams, so that they lose that personal note which grates upon strange ears and become enjoyable to others; he knows too how to modify them sufficiently so that their origin in prohibited sources is not easily detected. Further, he possesses the mysterious ability to mould his particular material until it expresses the ideas of his phantasy faithfully; and then he knows how to attach to this reflection of his phantasy-life so strong a stream of pleasure that, for a time at least, the repressions are out-balanced and dispelled by it. When he can do all this, he opens out to others the way back to the comfort and consolation of their own unconscious sources of pleasure, and so reaps their gratitude and admiration; then he has won—through his phantasy—what before he could only win in phantasy: honour, power, and the love of women.

## TWENTY-FOURTH LECTURE

### ORDINARY NERVOUSNESS

AFTER such a difficult piece of work as we got through in our last lecture I shall leave the subject for a time and turn to my audience.

For I know that you are dissatisfied. You

imagined that *A General Introduction to Psycho-Analysis* would be something quite different. You expected illustrations from life instead of theories; you will tell me that the story of the two children, on the ground-floor and in the mansion, revealed something of the causation of neurosis to you, except that it ought to have been an actual fact instead of an invention of my own. Or you will say that, when at the beginning I described two symptoms to you (not also imaginary, let us hope), and unfolded the solution of them and their connection with the lives of the patients, it threw some light on the meaning of symptoms, and you had hoped I would continue in the same way. Instead of doing so I gave you long-drawn-out and very obscure theories which were never complete, and to which I was constantly adding something; I dealt with conceptions which I had not yet introduced to you; I let go of descriptive explanation and took up the dynamic aspect and dropped this again for a so-called economic one; made it difficult for you to understand how many of these technical terms mean the same thing and are only exchanged for one another on account of euphony; I let vast conceptions, such as those of the pleasure and reality principles, and the inherited residue of phylogenetic development, appear, and then instead of explaining anything to you I let them drift away before your eyes out of sight.

Why did I not begin the introduction to the study of the neuroses with what you all know of nervousness, a thing that has long roused your interest, or with the peculiar nature of nervous persons, their incomprehensible reactions to human intercourse and external influences, their excitability, their unreliability, and their inability to do well in anything? Why not lead you step by step from an explanation of the simple every-day forms of nervousness to the problems of the enigmatic extreme manifestations?

Indeed, I cannot deny any of this or say that you are wrong. I am not so much in love with my powers of presentation as to imagine that every blemish in it is a peculiar charm. I think myself that I might with advantage to you have proceeded differently, and, indeed, such was my intention. But one cannot always carry through a reasoned scheme; something in the material itself often intervenes and takes possession of one and turns one from one's first intentions. Even such an ordinary task as the arrangement of familiar material is not en-

tirely subject to the author's will; it comes out in its own way and one can but wonder afterwards why it happened so and not otherwise.

One of the reasons probably is that my theme, an introduction to psycho-analysis, no longer covers this section dealing with the subject of the neuroses. The introduction to psycho-analysis lies in the study of errors and of dreams; the theory of neurosis is psycho-analysis itself. I do not think that in such a short time I could have given you any knowledge of the material contained in the theory of the neuroses except in this very concentrated form. It was a matter of presenting to you in their proper context the sense and meaning of symptoms, together with the external and internal conditions and mechanisms of symptom-formation. This I attempted to do; it is more or less the core of what psycho-analysis is able to offer today. In conjunction with it there was much to be said about the libido and its development, and something about that of the ego. You were already prepared by the preliminary lectures for the main principles of our method and for the broad aspects involved in the conceptions of the unconscious and of repression (resistance). In one of the following lectures you will learn at what point the work of psycho-analysis finds its organic continuation. So far I have not concealed from you that all our results proceed from the study of one single group only of nervous disorders—namely, the transference neuroses; and even so I have traced out the mechanism of symptom-formation only in the hysterical neurosis. Though you will probably have gained no very thorough knowledge and have not retained every detail, yet I hope that you have acquired a general idea of the means with which psycho-analysis works, the problems it has to deal with, and the results it has to offer.

I have ascribed to you a wish that I had begun the subject of the neuroses with a description of the neurotic's behaviour, and of the ways in which he suffers from his disorder, protects himself against it and adapts himself to it. This is certainly a very interesting subject, well worth studying, and not difficult to treat: nevertheless there are reasons against beginning with this aspect. The danger is that the unconscious will be overlooked, the great importance of the libido ignored, and that everything will be judged as it appears to the patient's own ego. Now it is obvious that his ego is not a reliable and impartial authority. The ego is, after all, the force which denies the existence of the

unconscious and has subjected it to repressions; how then can we trust its good faith where the unconscious is concerned? That which has been repressed consists first and foremost of the repudiated claims of the sexuality; it is perfectly self-evident that we shall never learn their extent and their significance from the ego's view of the matter. As soon as the nature of repression begins to dawn upon us we are advised not to allow one of the two contending parties, and certainly not the victorious one, to be judged in the dispute. We are forewarned against being misled by what the ego tells us. According to its evidence it would appear to have been the active force throughout, so that the symptoms arise by its will and agency; we know that to a large extent it has played a passive part, a fact which it then endeavours to conceal and to gloss over. It is true that it cannot always keep up this pretence—in the symptoms of the obsessional neurosis it has to confess to being confronted by something alien which it must strenuously resist.

It is certainly plain sailing enough for anyone who does not heed these warnings against taking the falsifications of the ego at their face-value; he will escape all the opposition which psycho-analysis has to encounter in accentuating the unconscious, sexuality, and the passivity of the ego. He can agree with Alfred Adler that the *nervous character* is the cause of the neurosis, instead of the result; but he will not be in a position to account for a single detail of symptom-formation or a single dream.

You will ask: "May it not be possible to do justice to the part played by the ego in nervousness and in symptom-formation without absolutely glaring neglect of the other factors discovered by psycho-analysis?" I reply: Certainly it must be possible, and some time or other it will be done; but the work which lies at hand for psycho-analysis is not suited for a beginning at this end. One can, no doubt, predict the point at which this task also will be included. There are neuroses, called by us the *narcissistic* neuroses, in which the ego is far more deeply involved than in those we have studied; analytic investigation of these disorders will enable us to estimate impartially and reliably the share taken by the ego in neurotic disease.

One of the relations the ego bears to its neurosis is, however, so conspicuous that it was quite appreciable from the beginning. It never seems to be absent; but it is most clearly discernible in a form of disorder which we are far

from understanding, the traumatic neurosis. You must know that in the causation and mechanism of all the various different forms of neurosis the same factors are found at work over and over again, only that in one type this factor and in another type that factor is of greatest significance in symptom-formation. It is just the same as with the personnel of a theatrical company, where every member plays a special type of part—hero, confidant, villain, etc.; each of them will choose a different piece for his own benefit-performance. Hence, the phantasies which are transformed into the symptoms are nowhere so manifest as in hysteria; the *counter-charges* (anti-cathexes) or reaction-formations of the ego dominate the picture in the obsessional neurosis; the mechanism which in dreams we called *secondary elaboration* is the prominent feature in the delusions of paranoia, and so on.

In the *traumatic neuroses*, especially in those arising from the terrors of war, we are particularly impressed by a self-seeking, egoistic motive, a straining towards protection and self-interest; this alone perhaps could not produce the disease, but it gives its support to the latter and maintains it once it has been formed. This tendency aims at protecting the ego from the dangers which led by their imminence to the outbreak of illness; nor does it permit of recovery until a repetition of the dangers appear to be no longer possible, or until some gain in compensation for the danger undergone has been received.

The ego takes a similar interest in the origin and maintenance of all the other forms of neurosis; we have said already that the symptom is supported by the ego because one side of it offers a satisfaction to the repressing ego-tendency. More than this, a solution of the conflict by a symptom-formation is the most convenient one, most in accordance with the pleasure-principle; for it undoubtedly spares the ego a severe and painful piece of internal labour. There are indeed cases in which the physician himself must admit that the solution of a conflict by a neurosis is the one most harmless and most tolerable socially. Do not be astonished to hear then that the physician himself occasionally takes sides with the illness which he is attacking. It is not for him to confine himself in all situations in life to the part of fanatic about health; he knows that there is *other* misery in the world besides neurotic misery—real unavoidable suffering—that necessity may even demand of a man that he

sacrifice his health to it, and he learns that such suffering in one individual may often avert incalculable hardship for many others. Therefore, although it may be said of every neurotic that he has taken *flight into illness*, it must be admitted that in many cases this flight is fully justified, and the physician who has perceived this state of things will silently and considerably retire.

But let us continue our discussion without regard to these exceptional cases. In the ordinary way it is apparent that by flight into neurosis the ego gains a certain internal *advantage through illness*, as we call it; under certain conditions a tangible external advantage, more or less valuable in reality, may be combined with this. To take the commonest case of this kind: a woman who is brutally treated and mercilessly exploited by her husband fairly regularly takes refuge in a neurosis, if her disposition admits of it. This will happen if she is too cowardly or too conventional to console herself secretly with another man, if she is not strong enough to defy all external reasons against it and separate from her husband, if she has no prospect of being able to maintain herself or of finding a better husband, and last of all, if she is still strongly attached sexually to this brutal man. Her illness becomes her weapon in the struggle against him, one that she can use for her protection, or misuse for purposes of revenge. She can complain of her illness, though she probably dare not complain of her marriage; her doctor is her ally; the husband who is otherwise so ruthless is required to spare her, to spend money on her, to grant her absence from home and thus some freedom from marital oppression. Whenever this external or *accidental* advantage through illness is at all pronounced, and no substitute for it can be found in reality, you need not look forward very hopefully to influencing the neurosis by your therapy.

You will now say that what I have just told you about the *advantage through illness* is all in favour of the view I have rejected, namely, that the ego itself desires the neurosis and creates it. But just a moment! Perhaps it means merely this: that the ego is pleased to accept the neurosis which it is in any case unable to prevent, and that if there is anything at all to be made out of it it makes the best of it. This is only one side of the matter. In so far as there is advantage in it the ego is quite happy to be on good terms with a neurosis, but there are also disadvantages to be considered. As a

rule it is soon apparent that by accepting a neurosis the ego has made a bad bargain. It has paid too heavily for the solution of the conflict; the sufferings entailed by the symptoms are perhaps as bad as those of the conflict they replace, and they may quite probably be very much worse. The ego wishes to be rid of the pain of the symptoms, but not give up its advantage through illness; and that is just what it cannot succeed in doing. It appears, therefore, that the ego was not quite so actively concerned in the matter throughout as it had thought, and we will keep this well in mind.

If, as physicians, you have much to do with neurotics, you will soon cease to expect that those who complain most bitterly of their illness will be most ready to accept your help and make least difficulty—quite the contrary. You will at all events easily understand that everything which contributes to the advantage through illness reinforces the resistance arising from the repressions, and increases the therapeutic difficulties. And there is yet another kind of advantage through illness, one which supervenes later than that born with the symptom, so to speak. When such a mental organization as the disease has persisted for a considerable time it seems finally to acquire the character of an independent entity; it displays something like a self-preservative instinct; it forms a kind of pact, a *modus vivendi*, with the other forces in mental life, even with those fundamentally hostile to it, and opportunities can hardly fail to arise in which it once more manifests itself as useful and expedient, thus acquiring a *secondary function* which again strengthens its position. Instead of taking an example from pathology let us consider a striking illustration in everyday life. A capable working-man earning his living is crippled by an accident in the course of his employment; he can work no more, but he gets a small periodical dole in compensation and learns how to exploit his mutilation as a beggar. His new life, although so inferior, nevertheless is supported by the very thing which destroyed his old life; if you were to remove his disability you would deprive him for a time of his means of subsistence, for the question would arise whether he would still be capable of resuming his former work. When a secondary exploitation of the illness such as this is formed in a neurosis we can range it alongside the first and call it a *secondary advantage through illness*.

I should like to advise you in a general way not to underestimate the practical importance

of the advantage through illness, and yet not to be too much impressed by its theoretical significance. Apart from the exceptions previously recognized, this factor always reminds one of the illustrations of "Intelligence in Animals" by Oberländer in *Fliegende Blätter*. An Arab is riding a camel along a narrow path cut in the side of a steep mountain. At a turn in the path he suddenly finds himself confronted by a lion ready to spring at him. There is no escape; on one side the abyss, on the other the sheer wall; retreat and flight are impossible; he gives himself up for lost. Not so the camel. He takes one leap with his rider into the abyss—and the lion is left a spectator. The remedies provided by neurosis avail the patient no better as a rule; perhaps because the solution of the conflict by a symptom-formation is after all an automatic process which may show itself inadequate to meet the demands of life, and involves man in a renunciation of his best and highest powers. The more honourable choice, if there be a choice, is to go down in fair fight with destiny.

I still owe you a further explanation of my motive in not taking ordinary nervousness as my starting-point. Perhaps you think I avoided doing so because it would have been more difficult to bring in evidence of the sexual origin of the neuroses in that way; but in this you would be mistaken. In the transference neuroses the symptoms have to be submitted to interpretation before we arrive at this; but in the ordinary forms of what are called the ACTUAL NEUROSES the aetiological significance of the sexual life is a crudely obvious fact which courts notice. I became aware of it more than twenty years ago, as one day I began to wonder why, when we examine nervous patients, we so invariably exclude from consideration all matters concerning their sexual life. Investigations on this point led to the sacrifice of my popularity with my patients, but in a very short time my efforts had brought me to this conclusion: that no neurosis—actual neurosis, I meant—is present where sexual life is normal. It is true that this statement ignores the individual differences in people rather too much, and it also suffers from the indefinite connotation inseparable from the word *normal*; but as a broad outline it has retained its value to this day. At that time I got so far as to be able to establish particular connections between certain forms of nervousness and certain injurious sexual conditions; I do not doubt that I could repeat these observations today if I

still had similar material for investigation. I noticed often enough that a man who contented himself with some kind of incomplete sexual satisfaction, e.g., with manual masturbation, would suffer from a definite type of actual neurosis, and that this neurosis would promptly give way to another form if he adopted some other equally unsatisfactory form of sexual life. I was then in a position to infer the change in his mode of sexual life from the alteration in the patient's condition; and I learnt to abide stubbornly by my conclusions until I had overcome the prevarications of my patients and had compelled them to give me confirmation. It is true that they then thought it advisable to seek other physicians who would not take so much interest in their sexual life.

It did not escape me at that time either that sexuality was not always indicated as the cause of a neurosis; one person certainly would fall ill because of some injurious sexual condition, but another because he had lost his fortune or recently sustained a severe organic illness. The explanation of these variations was revealed later, when insight was obtained into the inter-relationships suspected between the ego and the libido; and the further this subject was explored the more satisfactory became our insight into it. A person only falls ill of a neurosis when the ego loses its capacity to deal in some way or other with the libido. The stronger the ego the more easily can it accomplish this task; every weakening of the ego, from whatever cause, must have the same effect as an increase in the demands of the libido; that is, make a neurosis possible. There are yet other and more intimate relations between the ego and the libido, which I shall not go into now as we have not yet come to them in the course of our discussions. The most essential and most instructive point for us is that the fund of energy supporting the symptoms of a neurosis, in every case and regardless of the circumstances inducing their outbreak, is provided by the libido, which is thus put to an abnormal use.

Now I must point out to you the decisive difference between the symptoms of the *actual neuroses* and those of the *psychoneuroses*, with the first group of which (the transference neuroses) we have hitherto been so much occupied. In both the actual neuroses and the psychoneuroses the symptoms proceed from the libido; that is, they are abnormal ways of using it, substitutes for satisfaction of it. But the symptoms of an actual neurosis—headache, sensation of pain, an irritable condition of some

organ, the weakening or inhibition of some function—have no *meaning*, no signification in the mind. Not merely are they manifested principally in the body, as also happens, for instance with hysterical symptoms, but they are in themselves purely and simply physical processes; they arise without any of the complicated mental mechanisms we have been learning about. They really are, therefore, what psychoneurotic symptoms were for so long held to be. But then, how can they be expressions of the libido which we have come to know as a force at work in the mind? Now, really, the answer to that is very simple. Let me resurrect one of the very first objections ever made against psycho-analysis. It was said that the theories were an attempt to account for neurotic symptoms by psychology alone and that the outlook was consequently hopeless, since no illness could ever be accounted for by psychological theories. These critics were pleased to forget that the sexual function is not a purely mental thing, any more than it is merely a physical thing. It affects bodily life as well as mental life. Having learnt that the symptoms of the psychoneuroses express the mental consequences of some disturbance in this function, we shall not be surprised to find that the actual neuroses represent the direct somatic consequences of sexual disturbances.

Clinical medicine gives us a useful hint (recognized by many different investigators) towards comprehension of the actual neuroses. In the details of their symptomatology, and also in the peculiarity by which all the bodily systems and functions are affected together, they exhibit an unmistakable similarity with pathological conditions resulting from the chronic effect or the sudden removal of foreign toxins—i.e., with states of intoxication or of abstinence. The two groups of affections are brought still closer together by comparison with conditions like Basedow's disease<sup>1</sup> that have also been found to result from poisoning, not, however, from poisons derived externally, but from such as arise in the internal metabolism. In my opinion, these analogies necessitate our regarding the neuroses as the effects of disturbances in the sexual metabolism, due either to more of these sexual toxins being produced than the person can dispose of, or else to internal and even mental conditions which interfere with the proper disposal of these substances. Assumptions of this kind about the nature of sexual desire have found acceptance in the mind of

<sup>1</sup> i.e., Grave's disease, exophthalmic goitre.—TR.

the people since the beginning of time; love is called an *intoxication*, it can be induced by "potions"—in these ideas the agency at work is to some extent projected on to the outer world. We find occasion at this point to remember the erotogenic zones, and to reflect upon the proposition that sexual excitation may arise in the most various organs. Beyond this the subject of *sexual metabolism* or the *chemistry of sexuality* is an empty chapter: we know nothing about it, and cannot even determine whether to assume two kinds of sexual substances, to be called *male* and *female*, or to content ourselves with *one* sexual toxin as the agent of the stimuli effected by the libido. The edifice of psycho-analytic doctrine which we have erected is in reality but a superstructure, which will have to be set on its organic foundation at some time or other; but this foundation is still unknown to us.

As a science, psycho-analysis is characterized by the methods with which it works, not by the subject-matter with which it deals. These methods can be applied without violating their essential nature to the history of civilization, to the science of religion, and to mythology as well as to the study of the neuroses. Psycho-analysis aims at and achieves nothing more than the discovery of the unconscious in mental life. The problems of the actual neuroses, in which the symptoms probably arise through direct toxic injury, offer no point of attack for psycho-analysis; it can supply little towards elucidation of them and must leave this task to biological and medical research. Now perhaps you understand better why I chose this arrangement of my material. If I had intended an *Introduction to the Study of the Neuroses* it would undoubtedly have been correct to begin with the simple forms of (actual) neuroses and proceed from them to the more complicated psychical disorders resulting from disturbances of the libido. I should have had to collect from various quarters what we know or think we know about the former, and about the latter psycho-analysis would have been introduced as the most important technical means of obtaining insight into these conditions. An *Introduction to Psycho-Analysis* was what I had undertaken and announced, however; I thought it more important to give you an idea of psycho-analysis than to teach you something about the neuroses; and therefore the actual neuroses which yield nothing towards the study of psycho-analysis could not suitably be put in the foreground. I think, too,

that my choice was the wiser for you, since the radical axioms and far-reaching connections of psycho-analysis make it worthy of every educated person's interest; the theory of the neuroses, however, is a chapter of medicine like any other.

However, you are justified in expecting that we should take some interest in the actual neuroses; their close clinical connection with the psycho-neuroses even necessitates this. I will tell you then that we distinguish three pure forms of actual neurosis: *neurasthenia*, *anxiety-neurosis* and *hypochondria*. Even this classification has been disputed; the terms are certainly all in use, but their connotation is vague and unsettled. There are some medical men who are opposed to all discrimination in the confusing world of neurotic manifestations, who object to any distinguishing of clinical entities or types of disease, and do not even recognize the difference between actual neuroses and psychoneuroses; in my opinion they go too far, and the direction they have chosen does not lead to progress. The three kinds of neurosis named above are occasionally found in a pure form; more frequently, it is true, they are combined with one another and with a psychoneurotic affection. This fact need not make us abandon the distinctions between them. Think of the difference between the science of minerals and that of ores in mineralogy: the minerals are classified individually, in part no doubt because they are frequently found as crystals, sharply differentiated from their surroundings; the ores consist of mixtures of minerals which have indeed coalesced, not accidentally, but according to the conditions at their formation. In the theory of the neuroses we still understand too little of the process of their development to formulate anything similar to our knowledge of ores; but we are certainly working in the right direction in first isolating from the mass the recognizable clinical elements, which are comparable to the individual minerals.

A noteworthy connection between the symptoms of the actual neuroses and the psychoneuroses adds a valuable contribution to our knowledge of symptom-formation in the latter; the symptom of the actual neurosis is frequently the nucleus and incipient stage of the psychoneurotic symptom. A connection of this kind is most clearly observable between *neurasthenia* and the transference neurosis known as *conversion-hysteria*, between the *anxiety-neurosis* and *anxiety-hysteria*, but also between

hypochondria and forms of a neurosis which we shall deal with later on, namely, paraphrenia (dementia praecox and paranoia). As an example, let us take an hysterical headache or backache. Analysis shows that, by means of condensation and displacement, it has become a substitutive satisfaction for a whole series of libidinal phantasies or memories; at one time, however, this pain was real, a direct symptom of a sexual toxin, the bodily expression of a sexual excitation. We do not by any means maintain that all hysterical symptoms have a nucleus of this kind, but it remains true that this very often is so, and that all effects (whether normal or pathological) of the libidinal excitation upon the body are especially adapted to serve the purposes of hysterical symptom-formation. They play the part of the grain of sand which the oyster envelops in mother-of-pearl. The temporary signs of sexual excitation accompanying the sexual act serve the psychoneurosis in the same way, as the most suitable and convenient material for symptom-formation.

There is a similar process of special diagnostic and therapeutic interest. In persons who are disposed to be neurotic without having yet developed a neurosis on a grand scale, some morbid organic condition—perhaps an inflammation, or an injury—very commonly sets the work of symptom-formation in motion; so that the latter process swiftly seizes upon the symptom supplied by reality, and uses it to represent those unconscious phantasies that have only been lying in wait for some means of expression. In such a case, the physician will try first one therapy and then the other; will either endeavour to abolish the organic foundation on which the symptom rests, without troubling about the clamorous neurotic elaboration of it; or will attack the neurosis which this opportunity has brought to birth, while leaving on one side the organic stimulus which incited it. Sometimes one and sometimes the other procedure will be found justified by success; no general rules can be prescribed for mixed cases of this kind.

## TWENTY-FIFTH LECTURE

### ANXIETY

You will certainly have judged the information that I gave you in the last lecture about ordinary nervousness as the most fragmentary and most inadequate of all my accounts. I know that it was; and I expect that nothing

surprised you more than that I made no mention of the *anxiety* which most nervous people complain of and themselves describe as their most terrible burden. Anxiety or dread can really develop tremendous intensity and in consequence be the cause of the maddest precautions. But in this matter at least I wished not to cut you short; on the contrary, I had determined to put the problem of nervous anxiety to you as clearly as possible and to discuss it at some length.

*Anxiety* (or *dread*) itself needs no description; everyone has personally experienced this sensation, or to speak more correctly this affective condition at some time or other. But in my opinion not enough serious consideration has been given to the question why nervous persons in particular suffer from anxiety so much more intensely, and so much more altogether, than others. Perhaps it has been taken for granted that they should; indeed, the words *nervous* and *anxious* are used interchangeably, as if they meant the same thing. This is not justifiable, however; there are anxious people who are otherwise not in any way nervous and there are, besides, neurotics with numerous symptoms who exhibit no tendency to dread.

However this may be, one thing is certain, that the problem of anxiety is a nodal point, linking up all kinds of most important questions; a riddle, of which the solution must cast a flood of light upon our whole mental life. I do not claim that I can give you a complete solution; but you will certainly expect psycho-analysis to have attacked this problem too in a different manner from that adopted by academic medicine. Interest there centres upon the anatomical processes by which the anxiety condition comes about. We learn that the medulla oblongata is stimulated, and the patient is told that he is suffering from a neurosis in the vagal nerve. The medulla oblongata is a wondrous and beauteous object; I well remember how much time and labour I devoted to the study of it years ago. But today I must say I know of nothing less important for the psychological comprehension of anxiety than a knowledge of the nerve-paths by which the excitations travel.

One may consider anxiety for a long time without giving a thought to nervousness. You will understand me at once when I describe this form of anxiety as OBJECTIVE ANXIETY, in contrast to neurotic anxiety. Now *real* anxiety or dread appears to us a very natural and rational thing; we should call it a reaction

to the perception of an external danger, of an injury which is expected and foreseen; it is bound up with the reflex of flight, and may be regarded as an expression of the instinct of self-preservation. The occasions of it, i.e., the objects and situations about which anxiety is felt, will obviously depend to a great extent upon the state of the person's knowledge and feeling of power regarding the outer world. It seems to us quite natural that a savage should be afraid of a cannon or of an eclipse of the sun, while a white man who can handle the weapon and foretell the phenomenon remains unafraid in the same situation. At other times, it is knowledge itself which inspires fear, because it reveals the danger sooner; thus a savage will recoil with terror at the sight of a track in the jungle which conveys nothing to an ignorant white man, but means that some wild beast is near at hand; and an experienced sailor will perceive with dread a little cloud on the horizon because it means an approaching hurricane, while to a passenger it looks quite insignificant.

The view that objective anxiety is rational and expedient, however, will on deeper consideration be admitted to need thorough revision. In face of imminent danger the only expedient behaviour, actually, would be first a cool appraisal of the forces at disposal as compared with the magnitude of the danger at hand, and then a decision whether flight or defence, or possibly attack, offered the best prospect of a successful outcome. Dread, however, has no place in this scheme; everything to be done will be accomplished as well and probably better if dread does not develop. You will see, too, that when dread is excessive it becomes in the highest degree inexpedient; it paralyses every action, even that of flight. The reaction to danger usually consists in a combination of the two things, the fear-affect and the defensive action; the frightened animal is afraid *and* flees, but the expedient element in this is the *flight*, not the *being afraid*.

One is tempted therefore to assert that the development of anxiety is never expedient; perhaps a closer dissection of the situation in dread will give us a better insight into it. The first thing about it is the *readiness* for danger, which expresses itself in heightened sensorial perception and in motor tension. This expectant readiness is obviously advantageous; indeed, absence of it may be responsible for grave results. It is then followed on the one hand by a motor action, taking the form pri-

marily of flight and, on a higher level, of defensive action; and on the other hand by the condition we call a sensation of *anxiety* or dread. The more the development of dread is limited to a flash, to a mere signal, the less does it hinder the transition from the state of anxious readiness to that of action, and the more expediently does the whole course of events proceed. The *anxious readiness* therefore seems to me the expedient element, and the *development* of anxiety the inexpedient element, in what we call anxiety or dread.

I shall not enter upon a discussion whether the words *anxiety*, *fear*, *fright*, mean the same or different things in common usage. In my opinion, *anxiety* relates to the condition and ignores the object, whereas in the word *fear* attention is directed to the object; *fright* does actually seem to possess a special meaning—namely, it relates specifically to the condition induced when danger is unexpectedly encountered without previous anxious readiness. It might be said, then, that anxiety is a protection against fright.

It will not have escaped you that a certain ambiguity and indefiniteness exists in the use of the word *anxiety*. It is generally understood to mean the subjective condition arising upon the perception of what we have called *developed* anxiety; such a condition is called an *affect*. Now what is an affect, in a dynamic sense? It is certainly something very complex. An affect comprises first of all certain motor innervations or discharges; and, secondly, certain sensations, which moreover are of two kinds—namely, the perceptions of the motor actions which have been performed, and the directly pleasurable or painful sensations which give the affect what we call its dominant note. But I do not think that this description penetrates to the essence of an affect. With certain affects one seems to be able to see deeper, and to recognize that the core of it, binding the whole complex structure together, is of the nature of a *repetition* of some particular very significant previous experience. This experience could only have been an exceedingly early impression of a universal type, to be found in the previous history of the species rather than of the individual. In order to be better understood I might say that an affective state is constructed like an hysterical attack, i.e., is the precipitate of a reminiscence. An hysterical attack is, therefore, comparable to a newly formed individual affect, and the normal affect to a universal hysteria which has become a heritage.

Do not imagine that what I am telling you now about affects is the common property of normal psychology. On the contrary, these conceptions have grown on the soil of psycho-analysis and are only indigenous there. What psychology has to say about affects—the James-Lange theory, for instance—is utterly incomprehensible to us psycho-analysts and impossible for us to discuss. We do not however regard what we know of affects as at all final; it is a first attempt to take our bearings in this obscure region. To continue, then: we believe we know what this early impression is which is reproduced as a repetition in the anxiety affect. We think it is the experience of *birth*—an experience which involves just such a concatenation of painful feelings, of discharges of excitation, and of bodily sensations, as to have become a prototype for all occasions on which life is endangered, ever after to be reproduced again in us as the dread or *anxiety* condition. The enormous increase in stimulation effected by the interruption of the renewal of blood (the internal respiration) was the cause of the anxiety experience at birth—the first anxiety was therefore toxically induced. The name *Angst* (anxiety)—*angustiae*, *Enge*, a narrow place, a strait—accentuates the characteristic tightening in the breathing which was then the consequence of a real situation and is subsequently repeated almost invariably with an affect. It is very suggestive, too, that the first anxiety state arose on the occasion of the separation from the mother. We naturally believe that the disposition to reproduce this first anxiety condition has become so deeply ingrained in the organism, through countless generations, that no single individual can escape the anxiety affect; even though, like the legendary Macduff, he “was from his mother’s womb untimely ripped” and so did not himself experience the act of birth. What the prototype of the anxiety condition may be for other animals than mammals we cannot say; neither do we know what the complex of sensations in them is which is equivalent to fear in us.

It may perhaps interest you to know how it was possible to arrive at such an idea as this—that birth is the source and prototype of the anxiety affect. Speculation had least of all to do with it; on the contrary, I borrowed a thought from the naïve intuitive mind of the people. Many years ago a number of young house-physicians, including myself, were sitting round a dinner-table, and one of the assistants at the obstetrical clinic was telling

us all the funny stories of the last midwives’ examination. One of the candidates was asked what it meant when the meconium (child’s excreta) was present in the waters at birth, and promptly replied: “That the child is frightened.” She was ridiculed and failed. But I silently took her part and began to suspect that the poor unsophisticated woman’s unerring perception had revealed a very important connection.

Now let us turn to neurotic anxiety; what are the special manifestations and conditions found in the anxiety of nervous persons? There is a great deal to be described here. First of all, we find a general apprehensiveness in them, a *free-floating* anxiety, as we call it, ready to attach itself to any thought which is at all appropriate, affecting judgments, inducing expectations, lying in wait for any opportunity to find a justification for itself. We call this condition *expectant dread* or *anxious expectation*. People who are tormented with this kind of anxiety always anticipate the worst of all possible outcomes, interpret every chance happening as an evil omen, and exploit every uncertainty to mean the worst. The tendency to this kind of expectation of evil is found as a character-trait in many people who cannot be described as ill in any other way, and we call them *over-anxious* or pessimistic; but a marked degree of expectant dread is an invariable accompaniment of the nervous disorder which I have called anxiety-neurosis and include among the actual neuroses.

In contrast to this type of anxiety, a second form of it is found to be much more circumscribed in the mind, and attached to definite objects and situations. This is the anxiety of the extraordinarily various and often very peculiar phobias. Stanley Hall, the distinguished American psychologist, has recently taken the trouble to designate a whole series of these phobias by gorgeous Greek titles; they sound like the ten plagues of Egypt, except that there are far more than ten of them. Just listen to the things that can become the object or content of a phobia: darkness, open air, open spaces, cats, spiders, caterpillars, snakes, mice, thunder, sharp points, blood, enclosed places, crowds, loneliness, crossing bridges, travelling by land or sea, and so on. As a first attempt to take one’s bearings in this chaos we may divide them into three groups. Many of the objects and situations feared are rather sinister, even to us normal people they have some connection with danger; and these phobias are not entirely

incomprehensible to us, although their intensity seems very much exaggerated. Most of us, for instance, have a feeling of repulsion upon encountering a snake. It may be said that the snake-phobia is universal in mankind. Charles Darwin has described most vividly how he could not control his dread of a snake that darted at him, although he knew that he was protected from it by a thick plate of glass. The second group consists of situations that still have some relation to danger, but to one that is usually belittled or not emphasized by us; most situation-phobias belong to this group. We know that there is more chance of meeting with a disaster in a railway train than at home—namely, a collision; we also know that a ship may sink, whereupon it is usual to be drowned; but we do not brood upon these dangers and we travel without anxiety by train and boat. Nor can it be denied that, if a bridge were to break at the moment we are crossing it, we should be hurled into the torrent, but that only happens so very occasionally that it is not a danger worth considering. Solitude too has its dangers, which in certain circumstances we avoid, but there is no question of never being able to endure it for a moment under any conditions. The same thing applies to crowds, enclosed spaces, thunderstorms, and so on. What is foreign to us in these phobias is not so much their content as their intensity. The anxiety accompanying a phobia is positively indescribable! And we sometimes get the impression that neurotics are not really at all fearful of those things which can, under certain conditions, arouse anxiety in us and which they call by the same names.

There remains a third group which is entirely unintelligible to us. When a strong full-grown man is afraid to cross a street or square in his own so familiar town, or when a healthy well-developed woman becomes almost senseless with fear because a cat has brushed against her dress or a mouse has scurried through the room, how can we see the connection with danger which is obviously present to these people? With this kind of animal-phobia it is no question of an increased intensity of common human antipathies; to prove the contrary, there are numbers of people who, for instance, cannot pass a cat without attracting and petting it. A mouse is a thing that so many women are afraid of, and yet it is at the same time a very favourite pet name; many a girl who is delighted to be called so by her lover will scream with terror at the sight of the dainty

little creature itself. The behaviour of the man who is afraid to cross streets and squares only suggests one thing to us—that he behaves like a little child. A child is directly taught that such situations are dangerous, and the man's anxiety, too, is allayed when he is led by someone across the open space.

The two forms of anxiety described, the *free-floating* expectant dread and that attached to phobias, are independent of each other. The one is not the other at a further stage; they are only rarely combined, and then as if fortuitously. The most intense general apprehensiveness does not necessarily lead to a phobia; people who have been hampered all their lives by agoraphobia may be quite free from pessimistic expectant dread. Many phobias, e.g., fear of open spaces, of railway travelling, are demonstrably acquired first in later life; others, such as fear of darkness, thunder, animals, seem to have existed from the beginning. The former signify serious illness, the latter are more of the nature of idiosyncrasies, peculiarities; anyone exhibiting one of these latter may be suspected of harbouring others similar to it. I must add that we group all these phobias under *anxiety-hysteria*, that is, we regard them as closely allied to the well-known disorder called conversion-hysteria.

The third form taken by neurotic anxiety brings us to an enigma; there is no visible connection at all between the anxiety and the danger dreaded. This anxiety occurs in hysteria, for instance, accompanying the hysterical symptoms; or under various conditions of excitement in which, it is true, we should expect some affect to be displayed, but least of all an anxiety-affect; or without reference to any conditions, incomprehensible both to us and to the patient, an unrelated anxiety-attack. We may look far and wide without discovering a danger or an occasion which could even be exaggerated to account for it. These spontaneous attacks show, therefore, that the complex condition which we describe as anxiety can be split up into components. The whole attack can be represented (as a substitute) by a single intensively developed symptom—shuddering, faintness, palpitation of the heart, inability to breathe—and the general feeling which we recognize as anxiety may be absent or may have become unnoticeable. And yet these states which are termed *anxiety equivalents* have the same clinical and aetiological validity as anxiety itself.

Two questions arise now: Is it possible to

bring neurotic anxiety, in which such a small part or none at all is played by danger, into relation with *objective anxiety*, which is essentially a reaction to danger? And, how is neurotic anxiety to be understood? We will at present hold fast to the expectation that where there is anxiety there must be something of which one is afraid.

Clinical observation yields various clues to the comprehension of neurotic anxiety, and I will now discuss their significance with you.

(a) It is not difficult to see that expectant dread or general apprehensiveness stands in intimate relation to certain processes in the sexual life—let us say, to certain modes of libido-utilization. The simplest and most instructive case of this kind arises in people who expose themselves to what is called frustrated excitation, i.e., when a powerful sexual excitation experiences insufficient discharge and is not carried on to a satisfying termination. This occurs, for instance, in men during the time of an engagement to marry, and in women whose husbands are not sufficiently potent, or who perform the sexual act too rapidly or incompletely with a view to preventing conception. Under these conditions the libidinal excitation disappears and anxiety appears in place of it, both in the form of expectant dread and in that of attacks and anxiety-equivalents. The precautionary measure of *coitus interruptus*, when practised as a customary sexual régime, is so regularly the cause of anxiety-neurosis in men, and even more so in women, that medical practitioners would be wise to enquire first of all into the possibility of such an aetiology in all such cases. Innumerable examples show that the anxiety-neurosis vanishes when the sexual malpractice is given up.

So far as I know, the fact that a connection exists between sexual restraint and anxiety conditions is no longer disputed, even by physicians who hold aloof from psycho analysis. Nevertheless I can well imagine that they do not neglect to invert the connection, and to put forward the view that such persons are predisposed to apprehensiveness and consequently practice caution in sexual matters. Against this, however, decisive evidence is found in the reactions in women, in whom the sexual function is essentially passive, so that its course is determined by the treatment accorded by the man. The more *temperament*, i.e., the more inclination for sexual intercourse and capacity for satisfaction, a woman has, the more certainly will she react with anxiety manifesta-

tions to the man's impotence or to *coitus interruptus*; whereas such abuse entails far less serious results with anaesthetic women or those in whom the sexual hunger is less strong.

Sexual abstinence, which is nowadays so warmly recommended by physicians, of course only has the same significance for anxiety conditions when the libido which is denied a satisfactory outlet is correspondingly insistent, and is not being utilized to a large extent in sublimation. Whether or not illness will ensue is indeed always a matter of the quantitative factor. Even apart from illness, it is easy to see in the sphere of character-formation that sexual restraint goes hand in hand with a certain anxiousness and cautiousness, whereas fearlessness and a boldly adventurous spirit bring with them a free tolerance of sexual needs. However these relations may be altered and complicated by the manifold influences of civilization, it remains incontestible that, for the average human being, anxiety is closely connected with sexual restriction.

I have by no means told you all the observations which point to this genetic connection between libido and anxiety. There is, for instance, the effect upon anxiety states of certain periods of life, such as puberty and the menopause, in which the production of libido is considerably augmented. In many states of excitement, too, the mingling of sexual excitation with anxiety may be directly observed as well as the final replacement of the libidinal excitation by anxiety. The impression received from all this is a double one; first, that it is a matter of an accumulation of libido, debarred from its normal utilization; and secondly, that the question is one of somatic processes only. How anxiety develops out of sexual desire is at present obscure; we can only ascertain that desire is lacking and anxiety is found in its place.

(b) A second clue is obtained from analysis of the psychoneuroses, in particular, of hysteria. We have heard that anxiety frequently accompanies the symptoms in this disease, and that unattached anxiety may also be chronically present or come to expression in attacks. The patients cannot say what it is they fear; they link it up by unmistakable secondary elaboration to the most convenient phobias: of dying, of going mad, of having a stroke, etc. When we subject to analysis the situation in which the anxiety, or the symptom accompanied by anxiety, arose, we can as a rule discover what normal mental process has been checked in its

course and replaced by a manifestation of anxiety. To express it differently: we construe the unconscious process as though it had not undergone repression and had gone through unhindered into consciousness. This process would have been accompanied by a particular affect and now we discover, to our astonishment, that this affect, which would normally accompany the mental process through into consciousness, is in every case replaced by anxiety, no matter what particular type it had previously been. So that when we have a hysterical anxiety condition before us, its unconscious correlative may be an excitation of a similar character, such as apprehension, shame, embarrassment; or quite as possibly a *positive* libidinal excitation; or an antagonistic, aggressive one, such as rage or anger. Anxiety is thus general current coin for which all the affects are exchanged or can be exchanged, when the corresponding ideational content is under repression.

(c) A third observation is provided by patients whose symptoms take the form of obsessive acts, and who seem to be remarkably immune from anxiety. When we restrain them from carrying out their obsessive performances, their washing, their ceremonies, etc., or when they themselves venture an attempt to abandon one of their compulsions, they are forced by an appalling dread to yield to the compulsion and to carry out the act. We perceive that the anxiety was concealed under the obsessive act and that this is only performed to escape the feeling of dread. In the obsessional neurosis, therefore, the anxiety which would otherwise ensue is replaced by the symptom-formation; and when we turn to hysteria we find a similar relation existing—as a consequence of the process of repression either a pure developed anxiety, or anxiety with symptom-formation, or symptom-formation without anxiety. In an abstract sense, therefore, it seems correct to say that symptoms altogether are formed purely for the purpose of escaping the otherwise inevitable development of anxiety. Thus anxiety comes to the fore-front of our interest in the problems of the neuroses.

We concluded from our observations on the anxiety-neurosis that the diversion of the libido away from its normal form of utilization, a diversion which releases anxiety, took place on the basis of somatic processes. The analyses of hysterical and obsessional neuroses furnish the additional conclusion that a similar diversion with a similar result can follow from opposition on the part of institutions in the mind. We

know as much as this, therefore, about the origin of neurotic anxiety; it still sounds rather indefinite. But for the moment I know of no path which will take us further. The second task we undertook, that of establishing a connection between neurotic anxiety (abnormally utilized libido) and *objective anxiety* (which corresponds with the reaction to danger), seems even more difficult to accomplish. One would think there could be no comparison between the two things, and yet there are no means by which the sensations of neurotic anxiety can be distinguished from those of real anxiety.

The desired connection may be found with the help of the antithesis, so often put forward, between the ego and the libido. As we know, the development of anxiety is the reaction of the ego to danger and the signal preparatory to flight; it is, then, not a great step to imagine that in neurotic anxiety also the ego is attempting a flight, from the demands of its libido, and is treating this internal danger as if it were an external one. Then our expectation, that where anxiety is present there must be something of which one is afraid, would be fulfilled. The analogy goes further than this, however. Just as the tension prompting the attempt to flee from external danger is resolved into holding one's ground and taking appropriate defensive measures, so the development of neurotic anxiety yields to a symptom-formation, which enables the anxiety to be "bound."

Our difficulty in comprehension now lies elsewhere. The anxiety which signifies the flight of the ego from its libido is nevertheless supposed to have had its source in that libido. This is obscure, and we are warned not to forget that the libido of a given person is fundamentally part of that person and cannot be contrasted with him as if it were something external. It is the question of the topographical dynamics of anxiety-development that is still obscure to us—what kind of mental energies are being expended and to what systems do they belong? I cannot promise you to answer this question also; but we will not neglect to follow up two other clues, and in so doing will again summon direct observation and analytic investigation to aid our speculation. We will turn to the sources of anxiety in children, and to the origin of the neurotic anxiety which is attached to phobias.

Apprehensiveness is very common among children, and it is difficult enough to decide whether it is objective or neurotic anxiety. Indeed the very value of this distinction is called in question by the attitude of children them-

selves. For on the one hand we are not surprised that children are afraid of strangers, of strange objects and situations, and we account for this reaction to ourselves very easily by reflecting on their weakness and ignorance. Thus we ascribe to the child a strong tendency to objective anxiety and should regard it as only practical if this apprehensiveness had been transmitted by inheritance. The child would only be repeating the behaviour of prehistoric man and of primitive man today who, in consequence of his ignorance and helplessness, experiences a dread of anything new and strange, and of much that is familiar to him, none of which any longer inspires fear in us. It would also correspond to our expectations if the phobias of children were, at least in part, such as might be attributed to those primeval periods of human development.

On the other hand, it cannot be overlooked that children are not all equally apprehensive, and that the very children who are more than usually timid in the face of all kinds of objects and situations are just those who later become neurotic. The neurotic disposition is, therefore, betrayed, amongst other signs, by a marked tendency to objective anxiety; apprehensiveness rather than nervousness appears to be primary; and we arrive at the conclusion that the child, and later the adult, experiences a dread of the strength of his libido simply because he is afraid of everything. The derivation of anxiety from the libido itself would then be discarded; and investigation of the conditions of real anxiety would logically lead to the view that consciousness of personal weakness and helplessness—inferiority, as A. Adler calls it—when it is able to maintain itself into later life is the final cause of neurosis.

This sounds so simple and plausible that it has a claim on our attention. It is true that it would involve shifting the point of view from which we regard the problem of nervousness. That such feelings of inferiority do persist into later life—together with a disposition to anxiety and symptom-formation—seems so well established that much more explanation is required when, in an exceptional case, what we call *health* is the outcome. But what can be learnt from the close observation of apprehensiveness in children? The small child is first of all afraid of strange people; situations become important only on account of the people concerned in them, and objects always much later. But the child is not afraid of these strange people because he attributes evil intentions to

them, comparing their strength with his weakness and thus recognizing in them a danger to his existence, his safety, and his freedom from pain. Such a conception of a child, so suspicious and terrified of an overpowering aggressivity in the world, is a very poor sort of theoretical construction. On the contrary, the child starts back in fright from a strange figure because is used to—and therefore expects—a beloved and familiar figure, primarily his mother. It is his disappointment and longing which are transformed into dread—his libido, unable to be expended, and at that time not to be held suspended, is discharged through being converted into dread. It can hardly be a coincidence, too, that in this situation, which is the prototype of childish anxiety, the condition of the primary anxiety state during birth, a separation from the mother, is again reproduced.

The first phobias of situations in children concern darkness and loneliness; the former is often retained throughout life; common to both is the desire for the absent attendant, for the mother, therefore. I once heard a child who was afraid of the darkness call out: "Auntie, talk to me, I'm frightened." "But what good will that do? You can't see me"; to which the child replied: "If someone talks, it gets lighter." The longing felt in the darkness is thus transformed into fear of the darkness. Far from finding that neurotic anxiety is only secondary and a special case of objective anxiety, we see on the contrary that there is something in the small child which behaves like real anxiety and has an essential feature in common with neurotic anxiety—namely, origin in undischarged libido. Of genuine *objective anxiety* the child seems to bring very little into the world. In all those situations which can become the conditions of phobias later, on heights, on narrow bridges over water, in trains and boats, the small child shows no fear—the less it knows the less it fears. It is much to be wished that it inherited more of these life-preserving instincts; the task of looking after it and preventing it from exposing itself to one danger after another would have been very much lightened. Actually, you see, a child overestimates his powers, to begin with, and behaves without fear because he does not recognize dangers. He will run along the edge of the water, climb upon the window-sill, play with sharp things and with fire, in short, do anything that injures him and alarms his attendants. Since he cannot be allowed to learn it himself through bitter experience, it is entirely due to train-

ing that real anxiety does eventually awake in him.

Now if some children embrace this training in apprehensiveness very readily, and then find for themselves dangers which they have not been warned against, it is explicable on the ground that these children have inherently a greater amount of libidinal need in their constitution than others, or else that they have been spoiled early with libidinal gratifications. It is no wonder if those who later become nervous also belong to this type as children; we know that the most favourable circumstance for the development of a neurosis lies in the inability to tolerate a considerable degree of pent-up libido for any length of time. You will observe now that here the constitutional factor, which we have never denied, comes into its own. We protest only when others emphasize it to the exclusion of all other claims, and when they introduce the constitutional factor even where according to the unanimous findings both of observation and of analysis, it does not belong, or only plays a minor part.

Let us sum up the conclusions drawn from the observation of apprehensiveness in children: Infantile dread has very little to do with objective anxiety (dread of real danger), but is, on the other hand, closely allied to the neurotic anxiety of adults. It is derived, like the latter, from undischarged libido, and it substitutes some other external object or some situation for the love-object which it misses.

Now you will be glad to hear that the analysis of phobias has little more to teach us than we have learnt already. The same thing happens in them as in the anxiety of children; libido that cannot be discharged is continuously being converted into an apparently *objective* anxiety, and so an insignificant external danger is taken as a representative of what the libido desires. The agreement between the two forms of anxiety is not surprising; for infantile phobias are not merely prototypes of those which appear later in anxiety-hysteria, but they are a direct preliminary condition and prelude of them. Every hysterical phobia can be traced back to a childish dread, of which it is a continuation, even if it has a different content and must be called by a different name. The difference between the two conditions lies in their mechanism. In order that the libido should be converted into anxiety in the adult, it is no longer sufficient that the libido should be momentarily unable to be utilized. The adult has long since learned to maintain such libido sus-

pended, or to apply it in different ways. But, when the libido is attached to a mental excitation which has undergone repression, conditions similar to those in the child, in whom there is not yet any distinction between conscious and unconscious, are re-established; and, by a regression to the infantile phobia, a bridge, so to speak, is provided by which the conversion of libido into anxiety can be conveniently effected. As you will remember, we have treated repression at some length, but in so doing we have been concerned exclusively with the fate of the *idea* to be repressed; naturally, because this was easier to recognize and to present. But we have so far ignored the question of what happened to the *affect* attached to this idea, and now we learn for the first time that it is the immediate fate of the affect to be converted into anxiety, no matter what quality of affect it would otherwise have been had it run a normal course. This transformation of affect is, moreover, by far the more important effect of the process of repression. It is not so easy to present to you; for we cannot maintain the existence of unconscious affects in the same sense as that of unconscious ideas. An idea remains up to a point the same whether it is conscious or unconscious; we can indicate something that corresponds to an unconscious idea. But an affect is a process involving a discharge of energy, and it is to be regarded quite differently from an idea; without searching examination and clarification of our hypotheses concerning mental processes, we cannot tell what corresponds with it in the unconscious—and that cannot be undertaken here. However, we will preserve the impression we have gained, that the development of anxiety is closely connected with the unconscious system.

I said that conversion into anxiety, or better, discharge in the form of anxiety, was the immediate fate of libido which encounters repression; I must add that it is not the only or the final fate of it. In the neuroses, processes take place which are intended to prevent the development of anxiety, and which succeed in so doing by various means. In the phobias, for instance, two stages in the neurotic process are clearly discernible. The first effects the repressions and conversion of the libido into anxiety which is then attached to some external danger. The second consists in building up all those precautions and safeguards by which all contact with this externalized danger shall be avoided. Repression is an attempt at flight on the part of the ego from the libido, which it

feels to be dangerous; the phobia may be compared to a fortification against the outer danger, which now stands for the dreaded libido. The weakness of this defensive system in the phobias is, of course, that the fortress which is so well guarded from without remains exposed to danger from within; projection externally of danger from libido can never be a very successful measure. In the other neuroses, therefore, other defensive systems are employed against the possibility of the development of anxiety; this is a very interesting part of the psychology of the neuroses. Unfortunately it would take us too far afield and also it would require a thorough grounding in special knowledge of the subject. I will merely add this. I have already spoken of the *counter-charges* that are instituted by the ego upon repression, which must be maintained so that the repression can persist. It is the task of this counter-charge to carry out the various forms of defence against the development of anxiety after repression.

To return to the phobias: I may now hope that you realize how inadequate it is to attempt merely to explain their content, and to take no interest in them apart from their derivation—this or that object or situation which has been made into a phobia. The content of the phobia has an importance comparable to that of the manifest dream—it is a façade. With all due modifications, it is to be admitted that among the contents of the various phobias many are found which, as Stanley Hall points out, are specially suited by phylogenetic inheritance to become objects of dread. It is even in agreement with this that many of these dreaded things have no connection with danger, except through a *symbolic* relation to it.

Thus we are convinced of the quite central position which the problem of anxiety fills in the psychology of the neuroses. We have received a strong impression of how the development of anxiety is bound up with the fate of the libido and with the unconscious system. There is only one unconnected thread, only one gap in our structure, the fact, which after all can hardly be disputed, that *objective anxiety* must be regarded as an expression of the ego's instinct for self-preservation.

## TWENTY-SIXTH LECTURE

### THE THEORY OF THE LIBIDO: NARCISSISM

WE have repeatedly, and again quite recently, referred to the distinction between the sexual and the ego-instincts. First of all, repression

showed how they can oppose each other, how the sexual instincts are then apparently brought to submission, and required to procure their satisfaction by circuitous regressive paths, where in their impregnability they obtain compensation for their defeat. Then it appeared that from the outset they each have a different relation to the task mistress Necessity, so that their developments are different and they acquire different attitudes to the reality-principle. Finally we believe we can observe that the sexual instincts are connected by much closer ties with the affective state of anxiety than are the ego-instincts—a conclusion which in one important point only still seems incomplete. In support of it we may bring forward the further remarkable fact that want of satisfaction of hunger or thirst, the two most elemental of the self-preservative instincts, never results in conversion of them into anxiety, whereas the conversion of unsatisfied libido into anxiety is, as we have heard, a very well-known and frequently observed phenomenon.

Our justification for distinguishing between sexual and ego-instincts can surely not be contested; it is indeed assumed by the existence of the sexual instinct as a special activity in the individual. The only question is what significance is to be attached to this distinction, how radical and decisive we intend to consider it. The answer to this depends upon what we can ascertain about the extent to which the sexual instincts, both in their bodily and their mental manifestations, conduct themselves differently from the other instincts which we set against them; and how important the results arising from these differences are found to be. We have, of course, no motive for maintaining any difference in the fundamental nature of the two groups of instincts, and, by the way, it would be difficult to apprehend any. They both present themselves to us merely as descriptions of the sources of energy in the individual, and the discussion whether fundamentally they are one, or essentially different, and if one, when they became separated from each other, cannot be carried through on the basis of these concepts alone, but must be grounded on the biological facts underlying them. At present we know too little about this, and even if we knew more it would not be relevant to the task of psycho-analysis.

We should clearly, also, profit very little by emphasizing the primordial unity of all the instincts, as Jung has done, and describing all the energies which flow from them as *libido*.

We should then be compelled to speak of sexual and asexual libido, since the sexual function is not to be eliminated from the field of mental life by any such device. The name *libido*, however, remains properly reserved for the instinctual forces of the sexual life, as we have hitherto employed it.

In my opinion, therefore, the question how far the quite justifiable distinction between sexual and self-preservative instincts is to be carried has not much importance for psycho-analysis, nor is psycho-analysis competent to deal with it. From the biological point of view, there are certainly various indications that the distinction is important. For the sexual function is the only function of a living organism which extends beyond the individual and secures its connection with its species. It is undeniable that the exercise of this function does not always bring advantage to the individual, as do his other activities, but that, for the sake of an exceptionally high degree of pleasure, he is involved by this function in dangers which jeopardize his life and often enough exact it. Quite peculiar metabolic processes, different from all others, are probably required in order to preserve a portion of the individual's life as a disposition for posterity. And finally, the individual organism that regards itself as first in importance and its sexuality as a means like any other to its own satisfaction is, from a biological point of view, only an episode in a series of generations, a short-lived appendage to a germ-plasm which is endowed with virtual immortality, comparable to the temporary holder of an entail that will survive his death.

We are not concerned with such far-reaching considerations, however, in the psycho-analytic elucidation of the neuroses. By means of following up the distinction between the sexual and the ego-instincts we have gained the key to comprehension of the group of transference neuroses. We were able to trace back their origin to a fundamental situation in which the sexual instincts had come into conflict with the self-preservative instincts, or—to express it biologically, though at the same time less exactly—in which the ego in its capacity of independent individual organism had entered into opposition with itself in its other capacity as a member of a series of generations. Such a dissociation perhaps only exists in man, so that, taken all in all, his superiority over the other animals may come down to his capacity for neurosis. The excessive development of his libido and the rich elaboration of his mental

life (perhaps directly made possible by it) seem to constitute the conditions which give rise to a conflict of this kind. It is at any rate clear that these are the conditions under which man has progressed so greatly beyond what he has in common with the animals, so that his capacity for neurosis would merely be the obverse of his capacity for cultural development. However, these again are but speculations which distract us from the task in hand.

Our work so far has been conducted on the assumption that the manifestations of the sexual and the ego-instincts can be distinguished from one another. In the transference neuroses this is possible without any difficulty. We called the investments of energy directed by the ego towards the object of its sexual desires *libido*, and all the other investments proceeding from the self-preservative instincts its *interest*; and by following up the investments with libido, their transformations, and their final fates, we were able to acquire our first insight into the workings of the forces in mental life. The transference neuroses offered the best material for this exploration. The ego, however—its composition out of various organizations with their structure and mode of functioning—remained undiscovered; we were led to believe that analysis of other neurotic disturbances would be required before light could be gained on these matters.

The extension of psycho-analytic conceptions on to these other affections was begun in early days. Already in 1908, K. Abraham expressed the view after a discussion with me that the main characteristic of dementia praecox (reckoned as one of the psychoses) is that in this disease *the investments of objects with libido is lacking*. (*The Psycho-Sexual Differences between Hysteria and Dementia Praecox*). But then the question arose: what happens to the libido of dementia patients when it is diverted from its objects? Abraham did not hesitate to answer that it is turned back upon the ego, and that *this reflex reversion of it is the source of the delusions of grandeur in dementia praecox*. The delusion of grandeur is in every way comparable to the well-known overestimation of the object in a love-relationship. Thus we come for the first time to understand a feature of a psychotic affection by bringing it into relation to the normal mode of loving in life.

I will tell you at once that these early views of Abraham's have been retained in psycho-analysis and have become the basis of our position regarding the psychoses. We became slowly

accustomed to the conception that the libido, which we find attached to certain objects and which is the expression of a desire to gain some satisfaction in these objects, can also abandon these objects and set the ego itself in their place; and gradually this view developed itself more and more consistently. The name for this utilization of the libido—*NARCISSISM*—we borrowed from a perversion described by P. Näcke, in which an adult individual lavishes upon his own body all the caresses usually expended only upon a sexual object other than himself.

Reflection, then, at once disclosed that, if a fixation of this kind to the subject's own body and his own person can occur, it cannot be an entirely exceptional or meaningless phenomenon. On the contrary, it is probable that this *narcissism* is the universal original condition, out of which *object-love* develops later without thereby necessarily effecting a disappearance of the narcissism. One also had to remember the evolution of object-libido, in which to begin with many of the sexual impulses are gratified on the child's own body—as we say, auto-erotically—and that this capacity for auto-erotism accounts for the backwardness of sexuality in learning to conform to the reality-principle. Thus it appeared that auto-erotism was the sexual activity of the narcissistic phase of direction of the libido.

To put it briefly, we formed an idea of the relation between the ego-libido and the object-libido which I can illustrate to you by a comparison taken from zoology. Think of the simplest forms of life consisting of a little mass of only slightly differentiated protoplasmic substances. They extend protrusions which are called *pseudopodia* into which the protoplasm overflows. They can, however, again withdraw these extensions of themselves and re-form themselves into a mass. We compare this extending of protrusions to the radiation of libido on to the objects, while the greatest volume of libido may yet remain within the ego; we infer that under normal conditions ego-libido can transform itself into object-libido without difficulty and that this can again subsequently be absorbed into the ego.

With the help of these conceptions it is now possible to explain a whole series of mental states, or, to express it more modestly, to describe in terms of the libido-theory conditions that belong to normal life; for instance, the mental attitude pertaining to the conditions of "being in love," of organic illness, and of sleep. Of the condition of sleep we assumed that it is

founded upon a withdrawal from the outer world and a concentration upon the wish to sleep. We found that the nocturnal mental activity which is expressed in dreams served the purpose of the wish to sleep, and, moreover, that it was governed exclusively by egoistic motives. In the light of the libido-theory we may carry this further and say that sleep is a condition in which all investments of objects, the libidinal as well as the egoistic are abandoned and withdrawn again into the ego. Does not this shed a new light upon the recuperation afforded by sleep and upon the nature of fatigue in general? The likeness we see in the condition which the sleeper conjures up again every night to the blissful isolation of the intra-uterine existence is thus confirmed and amplified in its mental aspects. In the sleeper the primal state of the libido-distribution is again reproduced, that of absolute narcissism, in which libido and ego-interests dwell together still, united and indistinguishable in the self-sufficient self.

Two observations are in place here. First, how is the concept *narcissism* distinguished from *egoism*? In my opinion, narcissism is the libidinal complement of egoism. When one speaks of egoism one is thinking only of the *interests* of the person concerned, narcissism relates also to the satisfaction of his libidinal needs. It is possible to follow up the two separately for a considerable distance as practical motives in life. A man may be absolutely egoistic and yet have strong libidinal attachments to objects, in so far as libidinal satisfaction in an object is a need of his ego: his egoism will then see to it that his desires towards the object involve no injury to his ego. A man may be egoistic and at the same time strongly narcissistic (i.e., feel very little need for objects), and this again either in the form taken by the need for direct sexual satisfaction, or in those higher forms of feeling derived from the sexual needs which are commonly called *love*, and as such are contrasted with *sensuality*. In all these situations egoism is the self-evident, the constant element, and narcissism the variable one. The antithesis of egoism, *altruism*, is not an alternative term for the investment of an object with libido; it is distinct from the latter in its lack of the desire for sexual satisfaction in the object. But when the condition of love is developed to its fullest intensity, altruism coincides with the investment of an object with libido. As a rule, the sexual object draws to itself a portion of the ego's

narcissism, which becomes apparent in what is called the *sexual overestimation* of the object. If to this is added an altruism directed towards the object and derived from the egoism of the lover, the sexual object becomes supreme; it has entirely swallowed up the ego.

I think you will find it a relief if, after these scientific phantasies, which are after all very dry, I submit to you a poetic description of the *economic* contrast between the condition of narcissism and that of love in full intensity. I take it from a dialogue between Zuleika and her lover in Goethe's *Westöstliche Divan*:

#### Zuleika

*The slave, the lord of victories,  
The crowd, with single voice, confess  
In sense of personal being lies  
A child of earth's true happiness.  
There's not a life he need refuse  
If his true self he does not miss:  
There's not a thing he cannot lose  
If he remains the man he is.*

#### Hâtem

*So it is held! so well may be!  
But down a different track I come  
Of all the bliss earth holds for me  
I in Zuleika find the sum.  
Does she expend her being on me,  
Myself grows to myself of cost;  
Turns she away, then instantly  
I to my very self am lost.  
And then with Hâtem all were over;  
Though yet I should but change my state  
Swift, should she grace some happy lover,  
In him I were incorporate.<sup>1</sup>*

The second observation is an amplification of the theory of dreams. The way in which a dream originates is not explicable unless we assume that what is repressed in the unconscious has acquired a certain independence of the ego, so that it does not subordinate itself to the wish for sleep and maintains its investments, although all the object-investments proceeding from the ego have been withdrawn for the purpose of sleep. Only this makes it possible to understand how it is that this unconscious material can make use of the abrogation or diminution in the activities of the censorship which takes place at night, and that it knows how to mould the day's residue so as to form a forbidden dream-wish from the ma-

terial to hand in that residue. On the other hand, some of the resistance against the wish to sleep, and the withdrawal of libido thereby induced, may have its origin in an association already in existence between this residue and the repressed unconscious material. This important dynamic factor must, therefore, now be incorporated into the conception of dream-formation which we formed in our earlier discussions.

Certain conditions—organic illness, painful accesses of stimulation, an inflammatory condition of an organ—have clearly the effect of loosening the libido from its attachment to its objects. The libido, which has thus been withdrawn, attaches itself again to the ego in the form of a stronger investment of the diseased region of the body. Indeed, one may venture the assertion that in such conditions the withdrawal of the libido from its objects is more striking than the withdrawal of the egoistic interests from their concerns in the outer world. This seems to lead to a possibility of understanding hypochondria, in which some organ, without being perceptibly diseased, becomes in a very similar way the subject of solicitude on the part of the ego. I shall, however, resist the temptation to follow this up, or to discuss other situations which become explicable or capable of exposition on this assumption of a return of the object-libido into the ego; for I feel bound to meet two objections which I know have all your attention at the moment. First of all, you want to know why when I discuss sleep, illness, and similar conditions, I insist upon distinguishing between libido and interests, sexual instincts and ego-instincts, while the observations are satisfactorily explained by assuming a single uniform energy which is freely mobile, can invest either object or ego, and can serve the purposes of the one as well as of the other. Secondly, you will want to know how I can be so bold as to treat the detachment of the libido from its objects as the origin of a pathological condition, if such a transformation of object-libido into ego-libido—or into ego-energy in general—is a normal mental process repeated every day and every night.

The answer is: Your first objection sounds a good one. Examination of the conditions of sleep, illness, and falling in love would probably never have led to a distinction between ego-libido and object-libido, or between libido and interests. But in this you omit to take into account the investigations with which we start-

<sup>1</sup> Taken, with very slight modifications, from Edward Dowden's translation.—TR.

ed, in the light of which we now regard the mental situations under discussion. The necessity of distinguishing between libido and interests, between sexual and self-preservative instincts, has been forced upon us by our insight into the conflict from which the transference neuroses arise. We have to reckon with this distinction henceforth. The assumption that object-libido can transform itself into ego-libido, in other words, that we shall also have to reckon with an ego-libido, appears to be the only one capable of solving the riddle of what are called the narcissistic neuroses, e.g., *dementia praecox*, or of giving any satisfactory explanation of their likeness to hysteria and obsessions and differences from them. We then apply what we have found undeniably proved in these cases to illness, sleep, and the condition of intense love. We are at liberty to apply them in any direction and see where they will take us. The single conclusion which is not directly based on analytical experience is that libido is libido and remains so, whether it is attached to objects or to the ego itself, and is never transformed into egoistic interests, and vice versa. This statement, however, is another way of expressing the distinction between sexual instincts and ego-instincts which we have already critically examined, and which we shall hold to from heuristic motives until such time as it may prove valueless.

Your second objection, too, raises a justifiable question, but it is directed to a false issue. The withdrawal of object-libido into the ego is certainly not pathogenic; it is true that it occurs every night before sleep can ensue, and that the process is reversed upon awakening. The protoplasmic animalcule draws in its protrusions and sends them out again at the next opportunity. But it is quite a different matter when a definite, very forcible process compels the withdrawal of the libido from its objects. The libido that has then become narcissistic can no longer find its way back to its objects, and this obstruction in the way of the free movement of the libido certainly does prove pathogenic. It seems that an accumulation of narcissistic libido over and above a certain level becomes intolerable. We might well imagine that it was this that first led to the investment of objects, that the ego was obliged to send forth its libido in order not to fall ill of an excessive accumulation of it. If it were part of our scheme to go more particularly into the disorder of *dementia praecox* I would show you that the process which detaches the libido

from its objects and blocks the way back to them again is closely allied to the process of repression, and is to be regarded as a counterpart of it. In any case you would recognize familiar ground under your feet when you found that the preliminary conditions giving rise to these processes are almost identical, so far as we know at present, with those of repression. The conflict seems to be the same and to be conducted between the same forces. Since the outcome is so different from that of hysteria, for instance, the reason can only lie in some difference in the disposition. The weak point in the libido-development in these patients is found at a different phase of the development; the decisive fixation which, as you will remember, enables the process of symptom-formation to break out is at another point, probably at the stage of primary narcissism, to which *dementia praecox* finally returns. It is most remarkable that for all the narcissistic neuroses we have to assume fixation-points of the libido at very much earlier phases of development than those found in hysteria or the obsessional neurosis. You have heard, however, that the concepts we have elicited from the study of the transference neuroses also suffice to show us our bearings in the narcissistic neuroses, which are in practice so much more severe. There is a very wide community between them; fundamentally they are phenomena of a single class. You may imagine how hopeless a task it is for anyone to attempt to explain these disorders (which properly belong to psychiatry) without being first equipped with the analytic knowledge of the transference neuroses.

The picture formed by the symptoms of *dementia praecox*, incidentally a very variable one, is not determined exclusively by the symptoms arising from the forcing of the libido back from the objects and the accumulation of it as narcissism in the ego. Other phenomena occupy a large part of the field, and may be traced to the efforts made by the libido to reach its objects again, which correspond therefore to attempts at restitution and recovery. These are in fact the conspicuous, clamorous symptoms; they exhibit a marked similarity to those of hysteria, or more rarely of the obsessional neurosis; they are nevertheless different in every respect. It seems that in *dementia praecox* the efforts of the libido to get back to its objects, that is, to the mental idea of its objects, do really succeed in conjuring up something of them, something that at the same

time is only the shadow of them—namely, the verbal images, the words, attached to them. This is not the place to discuss this matter further, but in my opinion this reversed procedure on the part of the libido gives us an insight into what constitutes the real difference between a conscious and an unconscious idea.

This has now brought us into the field where the next advances in analytic work are to be expected. Since the time when we resolved upon our formulation of the conception of ego-libido, the narcissistic neuroses have become accessible to us; the task before us was to find the dynamic factors in these disorders, and at the same time to amplify our knowledge of mental life by a comprehension of the ego. The psychology of the ego, at which we are aiming, cannot be founded upon data provided by our own self-perceptions; it must be based, as is that of the libido, upon analysis of the disturbances and disintegrations of the ego. We shall probably think very little of our present knowledge of the fate of the libido, gained from the study of the transference neuroses, when that further, greater work has been achieved. But as yet we have not got very far towards it. The narcissistic neuroses can hardly be approached at all by the method which has availed for the transference neuroses; you shall soon hear why this is. With these patients it always happens that, after one has penetrated a little way, one comes up against a stone wall which cannot be surmounted. You know that in the transference neuroses, too, barriers of resistance of this kind are met with, but that it is possible bit by bit to pull them down. In the narcissistic neuroses the resistance is insuperable; at the most we can satisfy our curiosity by craning our necks for a glimpse or two at what is going on over the wall. Our technique will, therefore, have to be replaced by other methods; at present we do not know whether we shall succeed in finding a substitute. There is no lack of material with these patients; they bring forward a great deal, although not in answer to our questions; at present all we can do is to interpret what they say in the light of the understanding gained from the study of the transference neuroses. The agreement between the two forms of disease goes far enough to ensure us a satisfactory start with them. How much we shall be able to achieve by this method remains to be seen.

There are other difficulties, besides this, in the way of our progress. The narcissistic disorders and the psychoses related to them can

only be unriddled by observers trained in the analytic study of the transference neuroses. But our psychiatrists do not study psycho-analysis and we psycho-analysts see too little of psychiatric cases. We shall have to develop a breed of psychiatrists who have gone through the training of psycho-analysis as a preparatory science. A beginning in this direction is being made in America, where several of the leading psychiatrists lecture on psycho-analytic doctrines to their students, and where medical superintendents of institutions and asylums endeavour to observe their patients in the light of this theory. But all the same it has sometimes been possible for us here to take a peep over the wall of narcissism, so I will now proceed to tell you what we think we have discovered in this way.

The disease of paranoia, a chronic form of systematic insanity, has a very uncertain position in the attempts at classification made by present-day psychiatry. There is no doubt, however, that it is closely related to dementia praecox; I have in fact proposed that they should both be included under the common designation of *paraphrenia*. The forms taken by paranoia are described according to the content of the delusion, e.g., delusions of grandeur, of persecution, of jealousy, of being loved (erotomania), etc. We do not expect attempts at explanation from psychiatry; as an example, an antiquated and not very fair example, I grant, I will tell you the attempt which was made to derive one of these symptoms from another, by means of a piece of intellectual rationalization: The patient who has a primary tendency to believe himself persecuted draws from this the conclusion that he must necessarily be a very important person and therefore develops a delusion of grandeur. According to our analytic conception, the delusion of grandeur is the direct consequence of the inflation of the ego by the libido withdrawn from the investment of objects, a secondary narcissism ensuing as a return of the original early infantile form. In the case of delusions of persecution, however, we observed things which led us to follow up a certain clue. In the first place we noticed that in the great majority of cases the persecuting person was of the same sex as the persecuted one; this was capable of a harmless explanation, it is true, but in certain cases which were closely studied it appeared that the person of the same sex who had been most beloved while the patient was normal became the persecutor after the disease

broke out. A further development of this becomes possible through the well-known paths of association by which a loved person may be replaced by someone else, e.g., the father by masters or persons in authority. From these observations, which were continually corroborated, we drew the conclusion that persecutory paranoia is the means by which a person defends himself against a homosexual impulse which has become too powerful. The conversion of the affectionate feeling into the hate which, as is well-known, can seriously endanger the life of the loved and hated object then corresponds to the conversion of libidinal impulses into anxiety, which is a regular result of the process of repression. As an illustration I will quote the last case I had of this type. A young doctor had to be sent away from the place where he lived because he had threatened the life of the son of a university professor there who had previously been his greatest friend. He imputed superhuman power and the most devilish intentions to this friend; he was to blame for all the misfortunes which had occurred in recent years to the family of the patient and for all his ill-luck in public and in private. This was not enough, however; the wicked friend and his father, the professor, had caused the war and brought the Russians over the border; he had ruined his life in a thousand ways; our patient was convinced that the death of this criminal would be the end of all evil in the world. And yet his old love for him was still so strong that it had paralysed his hand when he had an opportunity of shooting his enemy at sight. In the short conversation which I had with the patient it came to light that this intimate friendship between the two men went right back to their school-days; on at least one occasion it had passed beyond the boundaries of friendship, a night spent together had been the occasion of complete sexual intercourse. The patient had never developed any of the feeling towards women that would have been natural at his age with his attractive personality. He had been engaged to a handsome, well-connected girl, but she had broken off the engagement because her lover was so cold. Years after, his disease broke out at the very moment when he had for the first time succeeded in giving full sexual gratification to a woman; as she encircled him in her arms in gratitude and devotion he suddenly felt a mysterious stab of pain running like a sharp knife round the crown of his head. Afterwards he described the sensation as being like that of the

incision made at a post-mortem to bare the brain; and as his friend was a pathological anatomist he slowly came to the conclusion that he alone could have sent him this woman as a temptation. Then his eyes began to be opened about the other persecutions of which he had been the victim by the machinations of his former friend.

But how about those cases in which the persecutor is of a different sex from that of the persecuted one, and which appear therefore to contradict our explanation of this disease as a defence against homosexual libido? Some time ago I had an opportunity of examining a case of the kind, and behind the apparent contradiction I was able to elicit a confirmation. A young girl imagined herself persecuted by a man with whom she had twice had intimate relations; actually she had first of all cherished the delusions against a woman who could be recognized to be a mother-substitute. Not until after the second meeting with him did she make the advance of transferring the delusional idea from the woman to the man; so that in this case also the condition that the sex of the persecutor is the same as that of the victim originally held good also. In her complaint to the lawyer and the doctor the patient had not mentioned the previous phase of her delusion and this gave rise to an apparent contradiction of our theory of paranoia.

The homosexual choice of object is originally more closely related to narcissism than the heterosexual; hence, when a strong unwelcome homosexual excitation suffers repudiation, the way back to narcissism is especially easy to find. I have so far had very little opportunity in these lectures of speaking about the fundamental plan on which the course of the love-impulse during life is based, so far as we know it; nor can I supplement it now. I will only select this to tell you: that the choice of object, the step forward in the development of the libido which comes after the narcissistic stage, can proceed according to two types. These are: either *the narcissistic type*, according to which, in place of the ego itself, someone as nearly as possible resembling it is adopted as an object; or *the anaelitic type* (*Anlehnungstypus*)<sup>1</sup> in which those persons who became prized on account of the satisfactions they rendered to the primal needs in life are chosen as objects by the libido also. A strong libido-fixation on the

<sup>1</sup> This name refers to the *dependence* of the sexual instincts on the self-preservative instincts for their first object, i.e., the suckling mother.—TR.

narcissistic type of object-choice is also found as a trait in the disposition of manifest homosexuals.

You will remember that in the first lecture given this session I described to you a case of delusional jealousy in a woman. Now that we have so nearly reached the end you will certainly want to know how we account for a delusion psycho-analytically. I have less to say about it than you would expect, however. The inaccessibility of delusions to logical arguments and to actual experience is to be explained, as it is with obsessions, by the connection they bear to the unconscious material which is both expressed by, and held in check by, the delusion or the obsession. The differences between the two are based on the topographical and dynamic differences in the two affections.

As with paranoia, so also with melancholia (under which, by the way, very different clinical types are classified), it has been possible to obtain a glimpse into the inner structure of the disorder. We have perceived that the self-reproaches with which these sufferers torment themselves so mercilessly actually relate to another person, to the sexual object they have lost or whom they have ceased to value on account of some fault. From this we concluded that the melancholic has indeed withdrawn his libido from the object, but that by a process which we must call *narcissistic identification* he has set up the object within the ego itself, projected it on to the ego. I can only give you a descriptive representation of this process, and not one expressed in terms of topography and dynamics. The ego itself is then treated as though it were the abandoned object; it suffers all the revengeful and aggressive treatment which is designed for the object. The suicidal impulses of melancholics also become more intelligible on the supposition that the bitterness felt by the diseased mind concerns the ego itself at the same time as, and equally with, the loved and hated objects. In melancholia, as in the other narcissistic disorders, a feature of the emotional life which, after Bleuler, we are accustomed to call *ambivalence* comes markedly to the fore; by this we mean a directing of antithetical feelings (affectionate and hostile) towards the same person. It is unfortunate that I have not been able to say more about ambivalence in these lectures.

There is also, besides the narcissistic, an hysterical form of identification which has long

been known to us. I wish it were possible to make the differences between them clear to you in a few definite statements. I can tell you something of the periodic and cyclic forms of melancholia which will interest you. It is possible in favourable circumstances—I have twice achieved it—to prevent the recurrence of the condition, or of its antithesis, by analytic treatment during the lucid intervals between the attacks. One learns from this that in melancholia and mania as well as other conditions a special kind of solution of a conflict is going on, which in all its pre-requisites agrees with those of the other neuroses. You may imagine how much there remains for psycho-analysis to do in this field.

I also told you that, by analysis of the narcissistic disorders, we hoped to gain some knowledge of the composition of the ego and of its structure out of various faculties and elements. We have made a beginning towards this at one point. From analysis of the delusion of observation we have come to the conclusion that in the ego there exists a faculty that incessantly watches, criticizes, and compares, and in this way is set against the other part of the ego. In our opinion, therefore, the patient reveals a truth which has not been appreciated as such when he complains that at every step he is spied upon and observed, that his very thought is known and examined. He has erred only in attributing this disagreeable power to something outside himself and foreign to him; he perceives within his ego the rule of a faculty which measures his actual ego and all his activities by an *ego-ideal*, which he has created for himself in the course of his development. We also infer that he created this ideal for the purpose of recovering thereby the self-satisfaction bound up with the primary infantile narcissism, which since those days has suffered so many shocks and mortification. We recognize in this self-criticizing faculty the ego censorship, the *conscience*; it is the same censorship as that exercised at night upon dreams, from which the repressions against inadmissible wish-excitations proceed. When this faculty disintegrates in the delusion of being observed, we are able to detect its origin and that it arose out of the influence of parents and those who trained the child, together with his social surroundings, by a process of identification with certain of these persons who were taken as a model.

These are some of the results yielded by the application of psycho-analysis to the narcissistic disorders.

sistic disorders. They are still not very numerous, and many of them still lack that sharpness of outline which cannot be achieved in a new field until some degree of familiarity has been attained. All of them have been made possible by employing the conception of ego-libido, or narcissistic libido, by means of which we can extend the conclusions established for the transference neuroses on to the narcissistic neuroses. But now you will put the question whether it is possible for us to bring all the disorders of the narcissistic neuroses and of the psychoses into the range of the libido-theory, for us to find the libidinal factor in mental life always and everywhere responsible for the development of disease, and for us never to have to attribute any part in the causation to the same alteration in the functions of the self-preservative instincts. Well now, it seems to me that decision on this point is not very urgent, and above all that the time is not yet ripe for us to make it; we may leave it calmly to be decided by advance in the work of science. I should not be astonished if it should prove that the capacity to induce a pathogenic effect were actually a prerogative of the libidinal impulses, so that the theory of the libido would triumph all along the line from the actual neuroses to the severest psychotic form of individual derangement. For we know it to be characteristic of the libido that it refuses to subordinate itself to reality in life, to necessity. But I consider it extremely probable that the ego-instincts are involved secondarily and that disturbances in their functions may be necessitated by the pathogenic affections of the libido. Nor can I see that the direction taken by our investigations will be invalidated if we should have to recognize that in severe psychosis the ego-instincts themselves are primarily deranged; the future will decide—for you, at least.

Let me return for a moment to anxiety, in order to throw light upon the one obscure point we left there. We said that the relation between anxiety and libido, otherwise so well defined, is with difficulty harmonized with the almost indisputable assumption that objective anxiety in the face of danger is the expression of the self-preservative instincts. But how if the anxiety-affect is provided, not by self-interest on the part of the ego-instincts, but by the ego-libido? The condition of anxiety is after all invariably detrimental; its disadvantage becomes conspicuous when it reaches an intense degree. It then interferes with the

action that alone would be expedient and would serve the purposes of self-preservation, whether it be flight or self-defence. Therefore if we ascribe the affective component of objective anxiety to the ego libido, and the action undertaken to the ego-preservative instincts, every theoretical difficulty will be overcome. You will hardly maintain seriously that we run away *because* we perceive fear? No, we perceive fear *and* we take to flight, out of the common impulse that is roused by the perception of danger. Men who have survived experiences of imminent danger to life tell us that they did not perceive any fear, that they simply acted—for instance, pointed their gun at the oncoming beast—which was undoubtedly the best thing they could do.

## TWENTY-SEVENTH LECTURE

### TRANSFERENCE

Now that we are coming to the end of our discussions you will feel a certain expectation which must not be allowed to mislead you. You are probably thinking that I surely have not led you through all these complicated mazes of psycho-analysis only to dismiss you at the end without a word about the therapy, upon which after all the possibility of undertaking psycho-analytic work depends. As a matter of fact I could not possibly leave out this aspect of it; for some of the phenomena belonging to it will teach you a new fact, without knowledge of which you would be quite unable to assimilate properly your understanding of the diseases we have been studying.

I know you do not expect directions in the technique of practising analysis for therapeutic purposes; you only want to know in a general way by what means the psycho-analytic therapy works and to gain a general idea of what it accomplishes. And you have an undeniable right to learn this; nevertheless I am not going to tell you—I am going to insist upon your finding out for yourselves.

Think for a moment! You have already learnt everything essential, from the conditions by which illness is provoked to all the factors which take effect within the diseased mind. Where is the opening in all this for therapeutic influence? First of all there is the hereditary disposition—we do not often mention it because it is so strongly emphasized in other quarters and we have nothing new to say about it. But do not suppose that we underestimate it; as practitioners, we are well aware of its

power. In any event we can do nothing to change it; for us also it is a fixed datum in the problem, which sets a limit to our efforts. Next, there is the influence of the experiences of childhood, which we are accustomed in analysis to rank as very important; they belong to the past, we cannot undo them. Then there is all that unhappiness in life which we have included under *frustration in reality*, from which all the absence of love in life proceeds—namely, poverty, family strife, mistaken choice in marriage, unfavourable social conditions, and the severity of the demands by which moral convention oppresses the individual. There is indeed a wide opening for a very effective treatment in all this; but it would have to follow the course of the dispensations of Kaiser Joseph in the Viennese legend—the benevolent despotism of a potentate before whose will men bow and difficulties disappear! But who are we that we can exert such beneficence as a therapeutic measure? Poor as we are and without influence socially, with our living to earn by our medical practice, we are not even in a position to extend our efforts to penniless folk, as other physicians with other methods can do; our treatment takes too much time and labour for that. But perhaps you are still clinging on to one of the factors put forward and believe you see an opening for our influence there. If the conventional restrictions imposed by society have had a part in the privations forced upon the patient, the treatment could give him the courage and even directly advise him to defy these obstacles, and to seize satisfactions and health for himself at the cost of failing to achieve an ideal which, though highly esteemed, is after all often set at naught by the world. Health is to be won by “free living,” then. There would be this blot upon analysis, to be sure, that it would not be serving general morality; what it gave to the individual it would take from the rest of the world.

But now, who has given you such a false impression of analysis? It is out of the question that part of the analytic treatment should consist of advice to “live freely”—if for no other reason because we ourselves tell you that a stubborn conflict is going on in the patient between libidinal desires and sexual repression, between sensual and ascetic tendencies. This conflict is not resolved by helping one side to win a victory over the other. It is true we see that in neurotics ascetism has gained the day; the result of which is that the suppressed sexual impulses have found a vent for themselves

in the symptoms. If we were to make victory possible to the sensual side instead, the disregarded forces repressing sexuality would have to indemnify themselves by symptoms. Neither of these measures will succeed in ending the inner conflict; one side in either event will remain unsatisfied. There are but few cases in which the conflict is so unstable that a factor like medical advice can have any effect upon it, and these cases do not really require analytic treatment. People who can be so easily influenced by physicians would have found their own way to that solution without this influence. After all, you know that a young man living in abstinence who makes up his mind to illicit sexual intercourse, or an unsatisfied wife who seeks compensation with a lover, does not as a rule wait for the permission of a physician, still less of an analyst, to do so.

In considering this question, people usually overlook the essential point of the whole difficulty—namely, that the pathogenic conflict in a neurotic must not be confounded with a normal struggle between conflicting impulses all of which are in the same mental field. It is a battle between two forces of which one has succeeded in coming to the level of the pre-conscious and conscious part of the mind, while the other has been confined on the unconscious level. That is why the conflict can never have a final outcome one way or the other; the antagonists meet each other as little as the whale and the polar bear in the well-known story. An effective decision can be reached only when they confront each other on the same ground. And, in my opinion, to accomplish this is the sole task of the treatment.

Besides this, I can assure you that you are quite misinformed if you imagine that advice and guidance concerning conduct in life forms an integral part of the analytic method. On the contrary, so far as possible we refrain from playing the part of mentor; we want nothing better than that the patient should find his own solutions for himself. To this end we expect him to postpone all vital decisions affecting his life, such as choice of career, business enterprises, marriage or divorce, during treatment and to execute them only after it has been completed. Now confess that you had imagined something very different. Only with certain very young or quite helpless and defenceless persons is it impossible to keep within such strict limitations as we should wish. With them we have to combine the positions of physician and educator; we are then well aware of

our responsibility and act with the necessary caution.

You must not be led away by my eagerness to defend myself against the accusation that in analytic treatment neurotics are encouraged to "live a free life" and conclude from it that we influence them in favour of conventional morality. That is at least as far removed from our purpose as the other. We are not reformers, it is true; we are merely observers; but we cannot avoid observing with critical eyes, and we have found it impossible to give our support to conventional sexual morality or to approve highly of the means by which society attempts to arrange the practical problems of sexuality in life. We can demonstrate with ease that what the world calls its code of morals demands more sacrifices than it is worth, and that its behaviour is neither dictated by honesty nor instituted with wisdom. We do not absolve our patients from listening to these criticisms; we accustom them to an unprejudiced consideration of sexual matters like all other matters; and if after they have become independent by the effect of the treatment they choose some intermediate course between unrestrained sexual licence and unconditional asceticism, our conscience is not burdened whatever the outcome. We say to ourselves that anyone who has successfully undergone the training of learning and recognizing the truth about himself is henceforth strengthened against the dangers of immorality, even if his standard of morality should in some respect deviate from the common one. Incidentally, we must beware of overestimating the importance of abstinence in affecting neurosis; only a minority of pathogenic situations due to frustration and the subsequent accumulation of libido thereby induced can be relieved by the kind of sexual intercourse that is procurable without any difficulty.

So you cannot explain the therapeutic effect of psycho-analysis by supposing that it permits patients free sexual indulgence; you must look round for something else. I think that one of the remarks I made while I was disposing of this conjecture on your part will have put you on the right track. Probably it is the substitution of something conscious for something unconscious, the transformation of the unconscious thoughts into conscious thoughts, that makes our work effective. You are right; that is exactly what it is. By extending the unconscious into consciousness the repressions are raised, the conditions of symptom-formation are abolished, and the pathogenic conflict ex-

changed for a normal one which must be decided one way or the other. We do nothing for our patients but enable this one mental change to take place in them; the extent to which it is achieved is the extent of the benefit we do them. Where there is no repression or mental process analogous to it to be undone there is nothing for our therapy to do.

The aim of our efforts may be expressed in various formulas—making conscious the unconscious, removing the repressions, filling in the gaps in memory; they all amount to the same thing. But perhaps you are dissatisfied with this declaration; you imagined the recovery of a nervous person rather differently, that after he had been subjected to the laborious process of psycho-analysis he would emerge a different person altogether, and then you hear that the whole thing only amounts to his having a little less that is unconscious and a little more that is conscious in him than before. Well, you probably do not appreciate the importance of an inner change of this kind. A neurotic who has been cured has really become a different person, although at bottom of course he remains the same—that is, he has become his best self, what he would have been under the most favourable conditions. That, however, is a great deal. Then when you hear of all that has to be done, of the tremendous exertion required to carry out this apparently trifling change in his mental life, the significance attached to these differences between the various mental levels will appear more comprehensible to you.

I will digress a moment to enquire whether you know what a *causal therapy* means? This name is given to a procedure which puts aside the manifestations of a disease and looks for a point of attack in order to eradicate the cause of the illness. Now is psycho-analysis a causal therapy or not? The answer is not a simple one, but it may give us an opportunity to convince ourselves of the futility of such questions. In so far as psycho-analytic therapy does not aim immediately at removing the symptoms it is conducted like a causal therapy. In other respects you may say it is not, for we have followed the causal chain back far beyond the repressions to the instinctive predispositions, their relative intensity in the constitution, and the aberrations in the course of their development. Now suppose that it were possible by some chemical means to affect this mental machinery, to increase or decrease the amount of libido available at any given moment, or to

reinforce the strength of one impulse at the expense of another—that would be a causal therapy in the literal sense, and our analysis would be the indispensable preliminary work of reconnoitring the ground. As you know, there is at present no question of any such influence upon the processes of the libido; our mental therapy makes its attack at another point in the concatenation, not quite at the place where we perceive the manifestations to be rooted, but yet comparatively far behind the symptoms themselves, at a place which becomes accessible to us in very remarkable circumstances.

What then have we to do in order to bring what is unconscious in the patient into consciousness? At one time we thought that would be very simple; all we need do would be to identify this unconscious matter and then tell the patient what it was. However, we know already that that was a short-sighted mistake. Our knowledge of what is unconscious in him is not equivalent to his knowledge of it; when we tell him what we know, he does not assimilate it *in place of* his own unconscious thoughts, but *alongside* of them, and very little has been changed. We have rather to regard this unconscious material topographically; we have to look for it in his memory at the actual spot where the repression of it originally ensued. This repression must be removed, and then the substitution of conscious thought for unconscious thought can be effected straightway. How is a repression such as this to be removed? Our work enters upon a second phase here; first, the discovery of the repression, and then the removal of the resistance which maintains this repression.

How can this resistance be got rid of? In the same way: by finding it out and telling the patient about it. The resistance, too, arises in a repression, either from the very one which we are endeavouring to dispel, or in one that occurred earlier. It is set up by the counter-charge which rose up to repress the repellent impulse. So that we now do just the same as we were trying to do before; we interpret, identify, and inform the patient; but this time we are doing it at the right spot. The counter-charge or the resistance is not part of the unconscious, but of the ego which co-operates with us, and this is so, even if it is not actually conscious. We know that a difficulty arises here in the ambiguity of the word *unconscious*, on the one hand, as a phenomenon, on the other hand, as a system. That sounds very obscure

and difficult; but after all it is only a repetition of what we have said before, is it not? We have come to this point already long ago. Well then, we expect that this resistance will be abandoned, and the counter-charge withdrawn, when we have made the recognition of them possible by our work of interpretation. What are the instinctive propelling forces at our disposal to make this possible? First, the patient's desire for recovery, which impelled him to submit himself to the work in co-operation with us, and secondly, the aid of his intelligence which we reinforce by our interpretation. There is no doubt that it is easier for the patient to recognize the resistance with his intelligence, and to identify the idea in his unconscious which corresponds to it, if we have first given him an idea which rouses his expectations in regard to it. If I say to you: "Look up at the sky and you will see a balloon," you will find it much more quickly than if I merely tell you to look up and see whether you can see anything; a student who looks through a microscope for the first time is told by the instructor what he is to see; otherwise he sees nothing, although it is there and quite visible.

And now for the fact! In quite a number of the various forms of nervous illness, in the hysterias, anxiety-conditions, obsessional neuroses, our hypothesis proves sound. By seeking out the repression in this way, discovering the resistances, indicating the repressed, it is actually possible to accomplish the task, to overcome the resistances, to break down the repression, and to change something unconscious into something conscious. As we do this we get a vivid impression of how, as each individual resistance is being mastered, a violent battle goes on in the soul of the patient—a normal mental struggle between two tendencies on the same ground, between the motives striving to maintain the counter charge and those which are ready to abolish it. The first of these are the old motives which originally erected the repression; among the second are found new ones more recently acquired which it is hoped will decide the conflict in our favour. We have succeeded in revivifying the old battle of the repression again, in bringing the issue, so long ago decided, up for revision again. The new contribution we make to it lies, first of all, in demonstrating that the original solution led to illness and in promising that a different one would pave the way to health, and secondly, in pointing out that the circumstances have all changed immensely since the time of that orig-

inal repudiation of these impulses. Then the ego was weak, infantile, and perhaps had reason to shrink with horror from the claims of the libido as being dangerous to it. Today it is strong and experienced and moreover has a helper at hand in the physician. So we may expect to lead the revived conflict through a better outcome than repression; and, as has been said, in hysteria, anxiety-neurosis, and the obsessional neurosis success in the main justifies our claims.

There are other forms of illness, however, with which our therapeutic treatment never is successful, in spite of the similarity of the conditions. In them also there was originally a conflict between ego and libido, leading to repression—although this conflict may be characterized by topographical differences from the conflict of the transference neuroses; in them too it is possible to trace out the point in the patient's life at which the repressions occurred; we apply the same method, are ready to make the same assurances, offer the same assistance by telling the patient what to look out for; and here also the interval in time between the present and the point at which the repressions were established is all in favour of a better outcome of the conflict. And yet we cannot succeed in overcoming one resistance or in removing one of the repressions. These patients, paranoiacs, melancholics, and those suffering from dementia praecox, remain on the whole unaffected, proof against psycho-analytic treatment. What can be the cause of this? It is not due to lack of intelligence; a certain degree of intellectual capacity must naturally be stipulated for analysis, but there is no deficiency in this respect in, for instance, the very quick-witted deductive paranoiac. Nor are any of the other propelling forces regularly absent: melancholics, for instance, in contrast to paranoiacs, experience a very high degree of realization that they are ill and that their sufferings are due to this; but they are not on that account any more accessible to influence. In this we are confronted with a fact that we do not understand, and are therefore called upon to doubt whether we have really understood all the conditions of the success possible with the other neuroses.

When we keep to consideration of hysterical and obsessional neurotics we are very soon confronted with a second fact, for which we were quite unprepared. After the treatment has proceeded for a while we notice that these patients behave in a quite peculiar manner towards ourselves. We thought indeed that we had taken

into account all the motive forces affecting the treatment and had reasoned out the situation between ourselves and the patient fully, so that it balanced like a sum in arithmetic; and then, after all, something seems to slip in which was quite left out of our calculation. This new and unexpected feature is in itself many-sided and complex; I will first of all describe some of its more frequent and simpler forms to you.

We observe then that the patient, who ought to be thinking of nothing but the solution of his own distressing conflicts, begins to develop a particular interest in the person of the physician. Everything connected with this person seems to him more important than his own affairs and to distract him from his illness. Relations with the patient then become for a time very agreeable; he is particularly docile, endeavours to show his gratitude wherever he can, exhibits a fineness of character and other good qualities which we had perhaps not anticipated in him. The analyst thus forms a very good opinion of the patient and values his luck in being able to render assistance to such an admirable personality. If the physician has occasion to see the patient's relatives he hears with satisfaction that this esteem is mutual. The patient at home is never tired of praising the analyst and attributing new virtues to him. "He has quite lost his head over you; he puts implicit trust in you; everything you say is like a revelation to him," say the relatives. Here and there, one among this chorus having sharper eyes will say: "It is positively boring the way he never speaks of anything but you: he quotes you all the time."

We will hope that the physician is modest enough to ascribe the patient's estimate of his value to the hopes of recovery which he has been able to offer to him, and to the widening in the patient's intellectual horizon consequent upon the surprising revelations entailed by the treatment and their liberating influence. The analysis too makes splendid progress under these conditions, the patient understands the suggestions offered to him, concentrates upon the tasks appointed by the treatment, the material needed—his recollections and associations—is abundantly available; he astonishes the analyst by the sureness and accuracy of his interpretations, and the latter has only to observe with satisfaction how readily and willingly a sick man will accept all the new psychological ideas that are so hotly contested by the healthy in the world outside. A general improvement in the patient's condition, objec-

tively confirmed on all sides, also accompanies this harmonious relationship in the analysis.

But such fair weather cannot last for ever. There comes a day when it clouds over. There begin to be difficulties in the analysis; the patient says he cannot think of anything more to say. One has an unmistakable impression that he is no longer interested in the work, and that he is casually ignoring the injunction given him to say everything that comes into his mind and to yield to none of the critical objections that occur to him. His behaviour is not dictated by the situation of the treatment; it is as if he had not made an agreement to that effect with the physician; he is obviously preoccupied with something which at the same time he wishes to reserve to himself. This is a situation in which the treatment is in danger. Plainly a very powerful resistance has risen up. What can have happened?

If it is possible to clear up this state of things, the cause of the disturbance is found to consist in certain intense feelings of affection which the patient has transferred on to the physician, not accounted for by the latter's behaviour nor by the relationship involved by the treatment. The form in which this affectionate feeling is expressed and the goal it seeks naturally depend upon the circumstances of the situation between the two persons. If one of them is a young girl and the other still a fairly young man, the impression received is that of normal love; it seems natural that a girl should fall in love with a man with whom she is much alone and can speak of very intimate things, and who is in the position of an adviser with authority—we shall probably overlook the fact that in a neurotic girl some disturbance of the capacity for love is rather to be expected. The farther removed the situation between the two persons is from this supposed example, the more unaccountable it is to find that nevertheless the same kind of feeling comes to light in other cases. It may be still comprehensible when a young woman who is unhappily married seems to be overwhelmed by a serious passion for her physician, if he is still unattached, and that she should be ready to seek a divorce and give herself to him, or, where circumstances would prevent this, to enter into a secret love-affair with him. That sort of thing, indeed, is known to occur outside psycho-analysis. But in this situation girls and women make the most astonishing confessions which reveal a quite peculiar attitude on their part to the therapeutic problem: they had

always known that nothing but love would cure them, and from the beginning of the treatment they had expected that this relationship would at last yield them what life had so far denied them. It was only with this hope that they had taken such pains over the analysis and had conquered all their difficulties in disclosing their thoughts. We ourselves can add: "and had understood so easily all that is usually so hard to accept." But a confession of this kind astounds us; all our calculations are blown to the winds. Could it be that we have omitted the most important element in the whole problem?

And actually it is so; the more experience we gain the less possible does it become for us to contest this new factor, which alters the whole problem and puts our scientific calculations to shame. The first few times one might think that the analytic treatment had stumbled upon an obstruction in the shape of an accidental occurrence, extraneous to its purpose and unconnected with it in origin. But when it happens that this kind of attachment to the physician regularly evinces itself in every fresh case, under the most unfavourable conditions, and always appears, even in circumstances of a positively grotesque incongruity—in elderly women, in relation to grey-bearded men, even on occasions when our judgment assures us that no temptations exist—then we are compelled to give up the idea of a disturbing accident and to admit that we have to deal with a phenomenon in itself essentially bound up with the nature of the disease.

The new fact which we are thus unwillingly compelled to recognize, we call *transference*. By this we mean a transference of feelings on to the person of the physician, because we do not believe that the situation in the treatment can account for the origin of such feelings. We are much more disposed to suspect that the whole of this readiness to develop feeling originates in another source; that it was previously formed in the patient, and has seized the opportunity provided by the treatment to transfer itself on to the person of the physician. The transference can express itself as a passionate petitioning for love, or it can take less extreme forms; where a young girl and an elderly man are concerned, instead of the wish to be wife or mistress, a wish to be adopted as a favourite daughter may come to light, the libidinous desire can modify itself and propose itself as a wish for an everlasting, but ideally platonic friendship. Many women understand how to

sublimate the transference and to mould it until it acquires a sort of justification for its existence; others have to express it in its crude, original, almost impossible form. But at bottom it is always the same, and its origin in the same source can never be mistaken.

Before we enquire where we are to range this new fact, we will amplify the description of it a little. How is it with our male patients? There at least we might hope to be spared the troublesome element of sex difference and sex attraction. Well, the answer is very much the same as with women. The same attachment to the physician, the same overestimation of his qualities, the same adoption of his interests, the same jealousy against all those connected with him. The sublimated kinds of transference are the forms more frequently met with between man and man, and the directly sexual declaration more rarely, in the same degree to which the manifest homosexuality of the patient is subordinated to the other ways by which this component-instinct can express itself. Also, it is in male patients that the analyst more frequently observes a manifestation of the transference which at the first glance seems to controvert the description of it just given—that is, the hostile or *negative* transference.

First of all, let us realize at once that the transference exists in the patient from the beginning of the treatment, and is for a time the strongest impetus in the work. Nothing is seen of it and one does not need to trouble about it as long as its effect is favourable to the work in which the two persons are co-operating. When it becomes transformed into a resistance, attention must be paid to it; and then it appears that the two different and contrasting states of mind have supervened in it and have altered its attitude to the treatment: first, when the affectionate attraction has become so strong and betrays signs of its origin in sexual desire so clearly that it was bound to arouse an inner opposition against itself; and secondly, when it consists in antagonistic instead of affectionate feeling. The hostile feelings as a rule appear later than the affectionate and under cover of them; when both occur simultaneously they provide a very good exemplification of that ambivalence in feeling which governs most of our intimate relationships with other human beings. The hostile feelings therefore indicate an attachment of feeling quite similar to the affectionate, just as defiance indicates a similar dependence upon the other person to that belonging to obedience, though with a reversed

prefix. There can be no doubt that the hostile feelings against the analyst deserve the name of *transference*, for the situation in the treatment certainly gives no adequate occasion for them; the necessity for regarding the negative transference in this light is a confirmation of our previous similar view of the positive or affectionate variety.

Where the transference springs from, what difficulties it provides for us, how we can overcome them, and what advantage we can finally derive from it, are questions which can only be adequately dealt with in a technical exposition of the analytic method; I can merely touch upon them here. It is out of the question that we should yield to the demands made by the patient under the influence of his transference; it would be nonsensical to reject them unkindly, and still more so, indignantly. The transference is overcome by showing the patient that his feelings do not originate in the current situation, and do not really concern the person of the physician, but that he is reproducing something that had happened to him long ago. In this way we require him to transform his *repetition* into *recollection*. Then the transference which, whether affectionate or hostile, every time seemed the greatest menace to the cure becomes its best instrument, so that with its help we can unlock the closed doors in the soul. I should like, however, to say a few words to dispel the unpleasant effects of the shock that this unexpected phenomenon must have been to you. After all, we must not forget that this illness of the patient's which we undertake to analyse is not a finally accomplished and, as it were, consolidated thing; but that it is growing and continuing its development all the time like a living thing. The beginning of the treatment puts no stop to this development; but, as soon as the treatment has taken a hold upon the patient, it appears that the entire productivity of the illness henceforward becomes concentrated in one direction—namely, upon the relationship to the physician. The transference then becomes comparable to the cambium layer between the wood and the bark of a tree, from which proceeds the formation of new tissue and the growth of the trunk in diameter. As soon as the transference has taken on this significance the work upon the patient's recollections recedes far into the background. It is then not incorrect to say that we no longer have to do with the previous illness, but with a newly created and transformed neurosis which has replaced the earlier one. This new edition

of the old disease has been followed from its inception, one sees it come to light and grow, and is particularly familiar with it since one is oneself its central object. All the patient's symptoms have abandoned their original significance and have adapted themselves to a new meaning, which is contained in their relationship to the transference; or else only those symptoms remain which were capable of being adapted in this way. The conquest of this new artificially acquired neurosis coincides with the removal of the illness which existed prior to the treatment, that is, with accomplishing the therapeutic task. The person who has become normal and free from the influence of repressed instinctive tendencies in his relationship to the physician remains so in his own life when the physician has again been removed from it.

The transference has this all-important, absolutely central significance for the cure in hysteria, anxiety-hysteria, and the obsessional neurosis, which are in consequence rightly grouped together as the *transference neuroses*. Anyone who has grasped from analytic experience a true impression of the fact of transference can never again doubt the nature of the suppressed impulses which have manufactured an outlet for themselves in the symptoms; and he will require no stronger proof of their libidinal character. We may say that our conviction of the significance of the symptoms as a substitutive gratification of the libido was only finally and definitely established by evaluating the phenomenon of transference.

Now, however, we are called upon to correct our former dynamic conception of the process of cure and to bring it into agreement with the new discovery. When the patient has to fight out the normal conflict with the resistances which we have discovered in him by analysis, he requires a powerful propelling force to influence him towards the decision we aim at, leading to recovery. Otherwise it might happen that he would decide for a repetition of the previous outcome, and allow that which had been raised into consciousness to slip back again under repression. The outcome in this struggle is not decided by his intellectual insight—it is neither strong enough nor free enough to accomplish such a thing—but solely by his relationship to the physician. In so far as his transference bears the positive sign, it clothes the physician with authority, transforms itself into faith in his findings and in his views. Without this kind of transference or with a

negative one, the physician and his arguments would never even be listened to. Faith repeats the history of its own origin; it is a derivative of love and at first it needed no arguments. Not until later does it admit them so far as to take them into critical consideration, if they have been offered by someone who is loved. Without this support, arguments have no weight with the patient, never do have any with most people in life. A human being is therefore on the whole only accessible to influence, even on the intellectual side, in so far as he is capable of investing objects with libido; and we have good cause to recognize, and to fear, in the measure of his narcissism a barrier to his susceptibility to influence, even by the best analytic technique.

The capacity for the radiation of libido towards other persons in object-investment must, of course, be ascribed to all normal people; the tendency to transference in neurotics, so called, is only an exceptional intensification of a universal characteristic. Now it would be very remarkable if a human character-trait of this importance and universality had never been observed and made use of. And this has really been done. Bernheim with unerring perspicacity, based the theory of hypnotic manifestations upon the proposition that all human beings are more or less open to suggestion, are *suggestible*. What he called *suggestibility* is nothing else but the tendency to transference, rather too narrowly circumscribed so that the negative transference did not come within its scope. But Bernheim could never say what suggestion actually was nor how it arises; it was an axiomatic fact to him and he could give no explanation of its origin. He did not recognize the dependence of *suggestibility* on sexuality, on the functioning of the libido. And we have to admit that we have only abandoned hypnosis in our methods in order to discover suggestion again in the shape of transference.

But now I will pause and let you take up the thread. I observe that an objection is invading your thoughts with such violence that it would deprive you of all power of attention if it were not given expression. "So now at last you have confessed that you too work with the aid of suggestion like the hypnotists. We have been thinking so all along. But then, what is the use of all these round-about routes by way of past experiences, discovering the unconscious material, interpreting and retranslating the distortions, and the enormous expenditure of time, trouble, and money, when, after all,

the only effective agent is suggestion? Why do you not suggest directly against the symptoms, as others do who are honest hypnotists? And besides, if you are going to make out that by these round-about routes you have made numerous important psychological discoveries, which are concealed in direct suggestion, who is to vouch for their validity? Are not they too the result of suggestion, of unintentional suggestion, that is? Cannot you impress upon the patient what you please and whatever seems good to you in this direction also?"

What you charge me with in this way is exceedingly interesting and must be answered. But I cannot do that today; our time is up. Till next time, then. You will see that I shall be answerable to you. Today I must finish what I began. I promised to explain to you, through the factor of transference, why it is that our therapeutic efforts have no success in the narcissistic neuroses.

I can do it in a few words, and you will see how simply the riddle is solved, and how well everything fits together. Experience shows that persons suffering from the narcissistic neuroses have no capacity for transference, or only insufficient remnants of it. They turn from the physician, not in hostility, but in indifference. Therefore they are not to be influenced by him; what he says leaves them cold, makes no impression on them, and therefore the process of cure which can be carried through with others, the revivification of the pathogenic conflict and the overcoming of the resistance due to the repressions, cannot be effected with them. They remain as they are. They have often enough undertaken attempts at recovery on their own account which have led to pathological results; we can do nothing to alter this.

On the basis of our clinical observations of these patients, we stated that they must have abandoned the investment of objects with libido and transformed object libido into ego-libido. By this we differentiated them from the first group of neurotics (hysteria, anxiety, and obsessional neurosis). Their behaviour during the attempt to cure them confirms this suspicion. They produce no transference, and are, therefore, inaccessible to our efforts, not to be cured by us.

## TWENTY-EIGHTH LECTURE

### THE ANALYTIC THERAPY

You know what we are going to discuss today. When I admitted that the influence of the

psycho-analytic therapy is essentially founded upon transference, i.e., upon suggestion, you asked me why we do not make use of direct suggestion, and you linked this up with a doubt whether, in view of the fact that suggestion plays such a large part, we can still vouch for the objectivity of our psychological discoveries. I promised to give you a comprehensive answer.

Direct suggestion is suggestion delivered directly against the forms taken by the symptoms, a struggle between your authority and the motives underlying the disease. In this struggle you do not trouble yourself about these motives, you only require the patient to suppress the manifestation of them in the form of symptoms. In the main it makes no difference whether you place the patient under hypnosis or not. Bernheim, with his characteristic acuteness, repeatedly stated that suggestion was the essence of the manifestations of hypnotism, and that hypnosis itself was already a result of suggestion, a suggested condition; he preferred to use suggestion in the waking state, which can achieve the same results in hypnosis.

Now which shall I take first, the results of experience or theoretical considerations?

Let us begin with experience. I sought out Bernheim in Nancy in 1889 and became a pupil of his; I translated his book on suggestion into German. For years I made use of hypnotic treatment, first with prohibitory suggestions and later combined with Breuer's system of the fullest inquiry into the patient's life; I can therefore speak from wide experience about the results of the hypnotic or suggestive therapy. According to an old medical saying, an ideal therapy should be rapid, reliable and not disagreeable to the patient; Bernheim's method certainly fulfilled two of these requirements. It was much more rapid, that is, incomparably more rapid in its course than the analytic, and it involved the patient in no trouble or discomfort. For the physician, it eventually became monotonous; it meant treating every case in the same way, always employing the same ritual to prohibit the existence of the most diverse symptoms, without being able to grasp anything of their meaning or significance. It was a sort of mechanical drudgery—hodman's work—not scientific work; it was reminiscent of magic, conjuring, and hocus-pocus, yet in the patient's interests one had to ignore that. In the third desideratum, however, it failed; it was not reliable in any respect. It could be

employed in certain cases only and not in others; with some much could be achieved by it, and with others very little, one never knew why. But worse than its capricious nature was the lack of permanence in the results; after a time, if one heard from the patient again, the old malady had reappeared or had been replaced by another. Then one could begin to hypnotize again. In the background there was the warning of experienced men against robbing the patient of his independence by frequent repetitions of hypnosis, and against accustoming him to this treatment as though it were a narcotic. It is true, on the other hand, that at times everything fell out just as one could wish; one obtained complete and lasting success with little difficulty; but the conditions of this satisfactory outcome remained hidden. In one case, when I had completely removed a severe condition by a short hypnotic treatment, it recurred unchanged after the patient (a woman) had developed ill feeling against me without just cause; then after a reconciliation I was able to effect its disappearance again and this time far more thoroughly; but it reappeared again when she had a second time become hostile to me. Another time I had the following experience: during the treatment of an especially obstinate attack in a patient whom I had several times relieved of nervous symptoms, she suddenly threw her arms round my neck. Whether one wished to do so or not, this kind of thing finally made it imperative to enquire into the problem of the nature and source of one's suggestive authority.

So much for experience; it shows that in abandoning direct suggestion we have given up nothing irreplaceable. Now let us link on to the facts a few comments. The exercise of the hypnotic method makes as little demand for effort on the part of the patient as it does on the physician. The method is in complete harmony with the view of the neuroses generally accepted by the majority of medical men. The practitioner says to the nervous person: "There is nothing the matter with you; it is merely nervousness, therefore a few words from me will scatter all your troubles to the winds in five minutes." But it is contrary to all our beliefs about energy in general that a minimal exertion should be able to remove a heavy load by approaching it directly without the assistance of any suitably devised appliance. In so far as the circumstances are at all comparable, experience shows that this trick cannot be performed successfully with the neuroses. I

know, however, that this argument is not unsailable; there are such things as explosions.

In the light of the knowledge we have obtained through psycho-analysis, the difference between hypnotic and psycho-analytic suggestion may be described as follows: The hypnotic therapy endeavours to cover up and as it were to whitewash something going on in the mind, the analytic to lay bare and to remove something. The first works cosmetically, the second surgically. The first employs suggestion to interdict the symptoms; it reinforces the repressions, but otherwise it leaves unchanged all the processes that have led to symptom-formation. Analytic therapy takes hold deeper down nearer the roots of the disease, among the conflicts from which the symptoms proceed; it employs suggestion to change the outcome of these conflicts. Hypnotic therapy allows the patient to remain inactive and unchanged, consequently also helpless in the face of every new incitement to illness. Analytic treatment makes as great demands for efforts on the part of the patient as on the physician, efforts to abolish the inner resistances. The patient's mental life is permanently changed by overcoming these resistances, is lifted to a higher level of development, and remains proof against fresh possibilities of illness. The labour of overcoming the resistances is the essential achievement of the analytic treatment; the patient has to accomplish it and the physician makes it possible for him to do this by suggestions which are in the nature of an *education*. It has been truly said therefore, that psycho-analytic treatment is a kind of *re-education*.

I hope I have now made clear to you the difference between our method of employing suggestion therapeutically and the method which is the only possible one in hypnotic therapy. Since we have traced the influence of suggestion back to the transference, you also understand the striking capriciousness of the effect in hypnotic therapy, and why analytic therapy is, within its limits, dependable. In employing hypnosis, we are entirely dependent upon the condition of the patient's transference and yet we are unable to exercise any influence upon this condition itself. The transference of a patient being hypnotized may be negative, or, as most commonly, ambivalent, or he may have guarded himself against his transference by adopting special attitudes; we gather nothing about all this. In psycho-analysis we work upon the transference itself, dissipate whatever stands in the way of it, and manipulate the

instrument which is to do the work. Thus it becomes possible for us to derive entirely new benefits from the power of suggestion; we are able to control it; the patient alone no longer manages his suggestibility according to his own liking, but in so far as he is amenable to its influence at all, we guide his suggestibility.

Now you will say that, regardless of whether the driving force behind the analysis is called *transference* or *suggestion*, the danger still remains that our influence upon the patient may bring the objective certainty of our discoveries into doubt; and that what is an advantage in therapy is harmful in research. This is the objection that has most frequently been raised against psycho-analysis; and it must be admitted that, even though it is unjustified, it cannot be ignored as unreasonable. If it were justified, psycho-analysis, after all, would be nothing else but a specially well-disguised and particularly effective kind of suggestive treatment; and all its conclusions about the experiences of the patient's past life, mental dynamics, the unconscious, and so on, could be taken very lightly. So our opponents think; the significance of sexual experiences in particular, if not the experiences themselves, we are supposed to have "put into the patient's mind," after having first concocted these conglomerations in our own corrupt minds. These accusations are more satisfactorily refuted by the evidence of experience than by the aid of theory. Anyone who has himself conducted psycho-analyses has been able to convince himself numberless times that it is impossible to suggest things to a patient in this way. There is no difficulty, of course, in making him a disciple of a particular theory, and thus making it possible for him to share some mistaken belief possibly harboured by the physician. He behaves like anyone else in this, like a pupil; but by this one has only influenced his intellect, not his illness. The solving of his conflicts and the overcoming of his resistances succeeds only when what he is told to look for in himself corresponds with what actually does exist in him. Anything that has been inferred wrongly by the physician will disappear in the course of the analysis; it must be withdrawn and replaced by something more correct. One's aim is, by a very careful technique, to prevent temporary successes arising through suggestion; but if they do arise no great harm is done, for we are not content with the first result. We do not consider the analysis completed unless all obscurities in the case are explained, the gaps in

memory filled out, and the original occasions of the repressions discovered. When results appear prematurely, one regards them as obstacles rather than as furtherances of the analytic work, and one destroys them again by continually exposing the transference on which they are founded. Fundamentally, it is this last feature which distinguishes analytic treatment from that of pure suggestion, and which clears the results of analysis from the suspicion of being the results of suggestion. In every other suggestive treatment, the transference is carefully preserved and left intact; in analysis, it is itself the object of the treatment and is continually being dissected in all its various forms. At the conclusion of the analysis the transference itself must be dissolved; if success then supervenes and is maintained it is not founded on suggestion, but on the overcoming of the inner resistances effected by the help of suggestion, on the inner change achieved within the patient.

That which probably prevents single effects of suggestion from arising during the treatment is the struggle that is incessantly being waged against the resistances, which know how to transform themselves into a negative (hostile) transference. Nor will we neglect to point to the evidence that a great many of the detailed findings of analysis, which would otherwise be suspected of being produced by suggestion, are confirmed from other, irreproachable sources. We have unimpeachable witnesses on these points, namely, demented and paranoiacs, who are of course quite above any suspicion of being influenced by suggestion. All that these patients relate in the way of phantasies and translations of symbols, which have penetrated through into their consciousness, corresponds faithfully with the results of our investigations into the unconscious of transference neurotics, thus confirming the objective truth of the interpretations made by us which are so often doubted. I do not think you will find yourselves mistaken if you choose to trust analysis in these respects.

We now need to complete our description of the process of recovery by expressing it in terms of the libido theory. The neurotic is incapable of enjoyment or of achievement—the first because his libido is attached to no real object, the last because so much of the energy which would otherwise be at his disposal is expended in maintaining the libido under repression, and in warding off its attempts to assert itself. He would be well, if the conflict

between his ego and his libido came to an end, and if his ego again had the libido at its disposal. The task of the treatment, therefore, consists in the task of loosening the libido from its previous attachments, which are beyond the reach of the ego, and in making it again serviceable to the ego. Now where is the libido of a neurotic? Easily found: it is attached to the symptoms, which offer it the substitutive satisfaction that is all it can obtain as things are. We must master the symptoms then, dissolve them—just what the patient asks of us. In order to dissolve the symptoms it is necessary to go back to the point at which they originated, to review the conflict from which they proceeded, and with the help of propelling forces which at that time were not available to guide it towards a new solution. This revision of the process of repression can only partially be effected by means of the memory-traces of the processes which led up to repression. The decisive part of the work is carried through by creating—in the relationship to the physician, in the *transference*—new editions of those early conflicts, in which the patient strives to behave as he originally behaved, while one calls upon all the available forces in his soul to bring him to another decision. The transference is thus the battlefield where all the contending forces must meet.

All the libido and the full strength of the opposition against it are concentrated upon the one thing, upon the relationship to the physician; thus it becomes inevitable that the symptoms should be deprived of their libido; in place of the patient's original illness appears the artificially acquired transference, the transference-disorder; in place of a variety of unreal objects of his libido appears the one object, also *phantastic*, of the person of the physician. This new struggle which arises concerning this object is by means of the analyst's suggestions lifted to the surface, to the higher mental levels, and there worked out as a normal mental conflict. Since a new repression is thus avoided, the opposition between the ego and the libido comes to an end; unity is restored within the patient's mind. When the libido has been detached from its temporary object in the person of the physician, it cannot return to its earlier objects, but is now at the disposal of the ego. The forces opposing us in this struggle during the therapeutic treatment are, on the one hand, the ego's aversion against certain tendencies on the part of the libido, which had expressed itself in repressing tendencies; and, on

the other hand, the tenacity or *adhesiveness* of the libido, which does not readily detach itself from objects it has once invested.

The therapeutic work thus falls into two phases: in the first, all the libido is forced away from the symptoms into the transference and there concentrated; in the second, the battle rages round this new object and the libido is made free from it. The change that is decisive for a successful outcome of this renewed conflict lies in the preclusion of repression, so that the libido cannot again withdraw itself from the ego by a flight into the unconscious. It is made possible by changes in the ego ensuing as a consequence of the analyst's suggestions. At the expense of the unconscious, the ego becomes wider by the work of interpretation which brings the unconscious material into consciousness; through education it becomes reconciled to the libido and is made willing to grant it a certain degree of satisfaction; and its horror of the claims of its libido is lessened by the new capacity it acquires to expend a certain amount of the libido in sublimation. The more nearly the course of the treatment corresponds with this ideal description the greater will be the success of the psycho-analytic therapy. Its barriers are found in the lack of mobility in the libido, which resists being released from its objects, and in the rigidity of the patient's narcissism, which will not allow more than a certain degree of object-transference to develop. Perhaps the dynamics of the process of recovery will become still clearer if we describe it by saying that, in attracting a part of it to ourselves through transference, we gather in the whole amount of the libido which has been withdrawn from the ego's control.

It is as well here to make clear that the distributions of the libido which ensue during and by means of the analysis afford no direct inference of the nature of its disposition during the previous illness. Given that a case can be successfully cured by establishing and then resolving a powerful father-transference to the person of the physician, it would not follow that the patient had previously suffered in this way from an unconscious attachment of the libido to his father. The father-transference is only the battlefield on which we conquer and take the libido prisoner; the patient's libido has been drawn hither away from other positions. The battlefield does not necessarily constitute one of the enemy's most important strongholds; the defence of the enemy's capital city need not be conducted immediately before its gates.

Not until after the transference has been again resolved can one begin to reconstruct in imagination the dispositions of the libido that were represented by the illness.

In the light of the libido theory there is a final word to be said about dreams. The dreams of a neurotic, like his *errors* and his free associations, enable us to find the meaning of the symptoms and to discover the dispositions of the libido. The forms taken by the wish-fulfilment in them show us what are the wish-impulses that have undergone repression, and what are the objects to which the libido has attached itself after withdrawal from the ego. The interpretation of dreams therefore plays a great part in psycho-analytic treatment, and in many cases it is for lengthy periods the most important instrument at work. We already know that the condition of sleep in itself produces a certain relaxation of the repressions. By this diminution in the heavy pressure upon it, the repressed desire is able to create for itself a far clearer expression in a dream than can be permitted to it by day in the symptoms. Hence the study of dreams becomes the easiest approach to a knowledge of the repressed unconscious, which is where the libido which has withdrawn from the ego belongs.

The dreams of neurotics, however, differ in no essential from those of normal people; they are indeed perhaps not in any way distinguishable from them. It would be illogical to account for the dreams of neurotics in a way that would not also hold good of the dreams of normal people. We have to conclude, therefore, that the difference between neurosis and health prevails only by day; it is not sustained in dream-life. It thus becomes necessary to transfer to healthy persons a number of conclusions arrived at as a result of the connections between the dreams and the symptoms of neurotics. We have to recognize that the healthy man as well possesses those factors in mental life which alone can bring about the formation of a dream or of a symptom, and we must conclude further that the healthy also have instituted repressions and have to expend a certain amount of energy to maintain them; that their unconscious minds, too, harbour repressed impulses which are still suffused with energy, and that *a part of the libido is in them also withdrawn from the disposal of the ego*. The healthy man, too, is therefore virtually a neurotic, but the only symptom that he *seems* capable of developing is a dream. To be sure, when you subject his waking life also to a critical investigation, you discover

something that contradicts this specious conclusion; for this apparently healthy life is pervaded by innumerable trivial and practically unimportant symptom-formations.

The difference between nervous health and nervous illness (neurosis) is narrowed down therefore to a practical distinction, and is determined by the practical result—how far the person concerned remains capable of a sufficient degree of capacity for enjoyment and active achievement in life. The difference can probably be traced back to the proportion of the energy which has remained free relative to that of the energy which has been bound by repression, i.e., it is a quantitative and not a qualitative difference. I do not need to remind you that this view provides a theoretical basis for our conviction that the neuroses are essentially amenable to cure, in spite of their being based on a constitutional disposition.

So much, therefore, in the way of knowledge of the characteristics of health may be inferred from the identity of the dreams dreamt by neurotic and by healthy persons. Of dreams themselves, however, a further inference must be drawn—namely, that it is not possible to detach them from their connection with neurotic symptoms; that we are not at liberty to believe that their essential nature is exhausted by compressing them into the formula of *a translation of thoughts into archaic forms of expression*; and that we are bound to conclude that they disclose dispositions of the libido and objects of desire which are actually in operation and valid at the moment.

We have now come very nearly to the end. Perhaps you are disappointed that, under the heading of psycho-analytic therapy, I have limited myself to theory and have told you nothing of the conditions under which the cure is undertaken, or of the results it achieves. I omit both, however: the first, because in fact I never intended to give you a practical training in the exercise of the analytic method; and the last, because I have several motives against it. At the beginning of these discussions I said emphatically that under favourable conditions we achieve cures that are in no way inferior to the most brilliant in other fields of medical therapy; I may perhaps add that these results could be achieved by no other method. If I said more I should be suspected of wishing to drown the depreciatory voices of our opponents by self-advertisement. Medical "colleagues" have, even at public congresses, repeatedly held

out a threat to psycho-analysts that by publishing a collection of the failures and harmful effects of analysis they will open the eyes of the injured public to the worthlessness of this method of treatment. Apart from the malicious, denunciatory character of such a measure, however, a collection of that kind would not even be valid evidence upon which a correct estimate of the therapeutic results of analysis might be formed. Analytic therapy, as you know, is still young; it needed many years to elaborate the technique, which could only be done in the course of the work under the influence of increasing experience. On account of the difficulties of imparting instruction in the methods, the beginner is thrown much more upon his own resources for development of his capacity than any other kind of specialist, and the results of his early years can never be taken as indicating the full possible achievements of analytic therapy.

Many attempts at treatment made in the beginning of psycho-analysis were failures because they were undertaken with cases altogether unsuited to the procedure, which nowadays we should exclude by following certain indications. These indications, however, could only be discovered by trying. In the beginning we did not know that paranoia and dementia præcox, when fully developed, are not amenable to analysis; we were still justified in trying the method on all kinds of disorders. Most of the failures of those early years, however, were not due to the fault of the physician, or to the unsuitability in the choice of subject, but to unpropitious external conditions. I have spoken only of the inner resistances, those on the part of the patient, which are inevitable and can be overcome. The external resistances which the patient's circumstances and surroundings set up against analysis have little theoretic interest but the greatest practical importance. Psycho-analytic treatment is comparable to a surgical operation and, like that, for its success it has the right to expect to be carried out under the most favourable conditions. You know the preliminary arrangements a surgeon is accustomed to make—a suitable room, a good light, expert assistance, exclusion of the relatives, and so on. Now ask yourselves how many surgical operations would be successful if they had to be conducted in the presence of the patient's entire family poking their noses into the scene of the operation and shrieking aloud at every cut. In psycho-analytic treatment, the intervention of the relatives is a positive danger

and, moreover, one which we do not know how to deal with. We are armed against the inner resistances of the patient, which we recognize as necessary, but how can we protect ourselves against these outer resistances? It is impossible to get round the relatives by any sort of explanation, nor can one induce them to hold aloof from the whole affair; one can never take them into one's confidence, because then we run the danger of losing the patient's trust in us, for he—quite rightly, of course—demands that the man he confides in should take his part. Anyone who knows anything of the dissensions commonly splitting up family life will not be astonished in his capacity of analyst to find that those nearest to the patient frequently show less interest in his recovery than in keeping him as he is. When, as so often occurs, the neurosis is connected with conflicts between different members of a family, the healthy person does not make much of putting his own interest before the patient's recovery. After all, it is not surprising that the husband does not favour a treatment in which, as he correctly supposes, his sins will all come to light; nor do we wonder at this, but then we cannot blame ourselves when our efforts remain fruitless and are prematurely broken off because the husband's resistance is added to that of the sick wife. We had simply undertaken something which, under the existing conditions, it was impossible to carry out.

Instead of describing many cases to you I will tell you of one only, in which I had to suffer for the sake of professional conscientiousness. I took a young girl—many years ago—for analytic treatment; for a considerable time previously she had been unable to go out of doors on account of a dread, nor could she stay at home alone. After much hesitation the patient confessed that her thoughts had been a good deal occupied by some signs of affection that she had noticed by chance between her mother and a well-to-do friend of the family. Very tactlessly—or else very cleverly—she then gave the mother a hint of what had been discussed during the analysis; she did this by altering her behaviour to her mother, by insisting that no one but her mother could protect her against the dread of being alone, and by holding the door against her when she attempted to leave the house. The mother herself had formerly been very nervous, but had been cured years before by a visit to a hydropathic establishment—or, putting it otherwise, we may say she had there made the acquaintance of the

man with whom she had established a relationship that had proved satisfying in more than one respect. Made suspicious by her daughter's passionate demands, the mother suddenly *understood* what the girl's dread signified. She had become ill in order to make her mother a prisoner and rob her of the freedom necessary for her to maintain her relations with her lover. The mother's decision was instantly taken; she put an end to the harmful treatment. The girl was sent to a home for nervous patients, and for many years was there pointed out as an "unhappy victim of psycho-analysis"; for just as long I was pursued by damaging rumours about the unfortunate results of the treatment. I maintained silence because I supposed myself bound by the rules of professional secrecy. Years later I learned from a colleague who had visited the home and there seen the girl with agoraphobia that the intimacy between the mother and the wealthy man was common knowledge, and that in all probability it was connived at by the husband and father. To this *secret* the girl's cure had been sacrificed.

In the years before the war, when the influx of patients from many countries made me independent of the goodwill or disfavour of my native city, I made it a rule never to take for treatment anyone who was not *sui juris*, independent of others in all the essential relations of life. Every psycho-analyst cannot make these stipulations. Perhaps you will conclude from my warnings about relatives that one should take the patient out of his family circle in the interests of analysis, and restrict this therapy to those living in private institutions. I could not support this suggestion, however; it is far more advantageous for the patients—those who are not in a condition of severe prostration, at least—to remain during the treatment in those circumstances in which they have to struggle with the demands that their ordinary life makes on them. But the relatives ought not to counteract this advantage by their behaviour, and above all should not oppose their hostility to one's professional efforts. But how are you going to induce people who are inaccessible to you to take up this attitude? You will naturally also conclude that the social atmosphere and degree of cultivation of the patient's immediate surroundings have considerable influence upon the prospects of the treatment.

This is a gloomy outlook for the efficacy of psycho-analysis as a therapy, even if we may explain the overwhelming majority of our fail-

ures by taking into account these disturbing external factors! Friends of analysis have advised us to counter-balance a collection of failures by drawing up a statistical enumeration of our successes. I have not taken up this suggestion either. I brought forward the argument that statistics would be valueless if the units collated were not alike, and the cases which had been treated were in fact not equivalent in many respects. Further, the period of time that could be reviewed was too short for one to be able to judge of the permanence of the cures; and of many cases it would be impossible to give any account. They were persons who had kept both their illness and their treatment secret, and whose recovery in consequence had similarly to be kept secret. The strongest reason against it, however, lay in the recognition of the fact that, in matters of therapy, humanity is in the highest degree irrational, so that there is no prospect of influencing it by reasonable arguments. A novelty in therapeutics is either taken up with frenzied enthusiasm, as for instance when Koch first published his results with tuberculin; or else it is regarded with abysmal distrust, as happened for instance with Jenner's vaccination, actually a heaven-sent blessing, but one which still has its implacable opponents. A very evident prejudice against psycho-analysis made itself apparent. When one had cured a very difficult case one would hear: "That is no proof of anything; he would have got well of himself after all this time." And when a patient who had already gone through four cycles of depression and mania came to me in an interval after the melancholia and three weeks later again began to develop an attack of mania, all the members of the family, and also all the high medical authorities who were called in, were convinced that the fresh attack could be nothing but a consequence of the attempted analysis. Against prejudice one can do nothing, as you can now see once more in the prejudices that each group of the nations at war has developed against the other. The most sensible thing to do is to wait and allow them to wear off with the passage of time. A day comes when the same people regard the same things in quite a different light from what they did before; why they thought differently before remains a dark secret.

It is possible that the prejudice against the analytic therapy has already begun to relax. The continual spread of analytic doctrine and the numbers of medical men taking up analytic treatment in many countries seem to point in

that direction. As a young man I was caught in just such a storm of indignation roused in the medical profession by the hypnotic suggestion-treatment, which nowadays is held up in opposition to psycho-analysis by the "sober-minded." As a therapeutic instrument, however, hypnotism did not bear out the hopes placed in it; we psycho-analysts may claim to be its rightful heirs and should not forget how much encouragement and theoretic enlightenment we owe to it. The harmful effects reported of psycho-analysis are essentially confined to transitory manifestations of an exacerbation of the conflict, which may occur when the analysis is clumsily handled, or when it is broken off suddenly. You have heard an account of what we do with our patients, and you can form your own judgment whether our efforts are likely to lead to lasting injury. Misuse of analysis is possible in various ways: the transference especially, in the hands of an unscrupulous physician,

is a dangerous instrument. But no medical remedy is proof against misuse; if a knife will not cut, neither will it serve a surgeon.

I have now reached the end. It is more than a conventional formality when I say that I myself am heavily oppressed by the many defects of the lectures I have delivered before you. I regret most of all that I have so often promised to return again in another place to a subject that I had just touched upon shortly, and that then the context in which I could keep my word did not offer itself. I undertook to give you an account of a thing that is still unfinished, still developing, and now my short summary itself has become an incomplete one. In many places I laid everything ready for drawing a conclusion, and then I did not draw it. But I could not aim at making you experts in psycho-analysis; I only wished to put you in the way of some understanding of it, and to arouse your interest in it.

# Beyond the Pleasure Principle<sup>1</sup>

## I

IN the psycho-analytical theory of the mind, we take it for granted that the course of mental processes is automatically regulated by the *pleasure-principle*: that is to say, we believe that any given process originates in an unpleasant state of tension and thereupon determines for itself such a path that its ultimate issue coincides with a relaxation of this tension, i.e., with avoidance of "pain" or with production of pleasure. When we consider the psychic processes under observation in reference to such a sequence we are introducing into our work the *economic* point of view. In our opinion, a presentation which seeks to estimate, not only the *topographical* and *dynamic*, but also the economic element, is the most complete that we can at present imagine, and deserves to be distinguished by the term *metapsychological*.

We are not interested in examining how far in our assertion of the pleasure-principle we have approached to or adopted any given philosophical system historically established. Our approach to such speculative hypotheses is by way of our endeavour to describe and account for the facts falling within our daily sphere of observation. Priority and originality are not among the aims which psycho-analysis sets itself, and the impressions on which the statement of this principle is founded are of so unmistakable a kind that it is scarcely possible to overlook them. On the other hand, we should willingly acknowledge our indebtedness to any philosophical or psychological theory that could tell us the meaning of these feelings of pleasure and "pain" which affect us so powerfully. Unfortunately, no theory of any value is forthcoming. It is the obscurest and least penetrable region of psychic life, and, while it is impossible for us to avoid touching on it, the most elastic hypothesis will be, to my mind, the best. We have decided to consider pleasure and "pain" in relation to the quantity of excitation present in the psychic life—and not confined in any way—along such lines that "pain" corresponds with an increase and pleasure with a decrease in this quantity. We do not thereby commit

ourselves to a simple relationship between the strength of the feelings and the changes corresponding with them, least of all, judging from psycho-physiological experiences, to any view of a direct proportion existing between them; probably the amount of diminution or increase in a given time is the decisive factor for feeling. Possibly there is room here for experimental work, but it is inadvisable for us analysts to go further into these problems until we can be guided by quite definite observations.

We cannot, however, profess the like indifference when we find that an investigator of such penetration as G. Th. Fechner has advocated a conception of pleasure and "pain," which in essentials coincides with that forced upon us by psycho-analytic work. Fechner's pronouncement is to be found in his short work, *Einige Ideen zur Schöpfungs- und Entwicklungsgeschichte der Organismen*, 1873 (Section XI, note p. 94), and reads as follows: "In so far as conscious impulses always bear a relation to pleasure or 'pain,' pleasure or 'pain' may be thought of in psycho-physical relationship to conditions of stability and instability, and upon this may be based the hypothesis I intend to develop elsewhere: viz., that every psycho-physical movement rising above the threshold of consciousness is charged with pleasure in proportion as it approximates—beyond a certain limit—to complete equilibrium, and with 'pain' in proportion as it departs from it beyond a certain limit; while between the two limits which may be described as the qualitative thresholds of 'pain' or pleasure, there is a certain area of aesthetic indifference."

The facts that have led us to believe in the supremacy of the pleasure-principle in psychic life also find expression in the hypothesis that there is an attempt on the part of the psychic apparatus to keep the quantity of excitation present as low as possible, or, at least, constant. This is the same supposition only put into another form, for, if the psychic apparatus operates in the direction of keeping down the quantity of excitation, all that tends to increase it must be felt to be contrary to function, that is to say, painful. The pleasure-principle is deduced from the principle of constancy; in reality, the principle of constancy was inferred

<sup>1</sup> Translated from the second German edition.—ED.

<sup>2</sup> The word *Unlust*, as in the phrase "pleasure-pain principle," has been translated as "pain"; pain without quotation marks signifies *Schmerz* in the original.—TR.

from the facts that necessitated our assumption of the pleasure-principle. On more detailed discussion we shall find further that this tendency on the part of the psychic apparatus postulated by us may be classified as a special case of Fechner's principle of the *tendency towards stability* to which he has related the pleasure-pain feelings.

In that event, however, it must be affirmed that it is not strictly correct to speak of a supremacy of the pleasure-principle over the course of psychic processes. If such existed, then the vast majority of our psychic processes would necessarily be accompanied by pleasure or would conduce to it, while the most ordinary experience emphatically contradicts any such conclusion. One can only say that a strong tendency towards the pleasure-principle exists in the psyche, to which, however, certain other forces or conditions are opposed, so that the ultimate issue cannot always be in accordance with the pleasure-tendency. Compare the comment of Fechner in a similar connection. "Therewithal it is to be noted that the tendency towards the goal does not imply the attainment of it and that in general the goal is only approximately attainable . . ." <sup>1</sup> If we now address ourselves to the question of what circumstances have the power to frustrate the successful carrying out of the pleasure-principle, we shall be treading on safer and better-known ground, and we can draw in abundant measure on our analytical experiences for the answer.

The first case of such a check on the pleasure-principle is perfectly familiar to us in the regularity of its occurrence. We know that the pleasure-principle is adjusted to a primary mode of operation on the part of the psychic apparatus, and that for the preservation of the organism amid the difficulties of the external world it is *ab initio* useless and indeed extremely dangerous. Under the influence of the instinct of the ego for self-preservation, it is replaced by the *reality-principle*, which, without giving up the intention of ultimately attaining pleasure, yet demands and enforces the postponement of satisfaction, the renunciation of manifold possibilities of it, and the temporary endurance of "pain" on the long and circuitous road to pleasure. The pleasure-principle, however, remains for a long time the method of operation of the sex impulses, which are not so easily educable, and it happens over and over again that, whether acting through these impulses or operating in the ego itself, it prevails

over the reality-principle to the detriment of the whole organism.

It is at the same time indubitable that the replacement of the pleasure-principle by the reality-principle can account only for a small part, and that not the most intense, of painful experiences. Another and no less regular source of "pain" proceeds from the conflicts and dissociations in the psychic apparatus during the development of the ego towards a more highly co-ordinated organization. Nearly all the energy with which the apparatus is charged,<sup>2</sup> comes from the inborn instincts, but not all of these are allowed to develop to the same stage. On the way, it over and again happens that particular instincts, or portions of them, prove irreconcilable in their aims or demands with others which can be welded into the comprehensive unity of the ego. They are, thereupon, split off from this unity by the process of repression, retained on lower stages of psychic development, and for the time being cut off from all possibility of gratification. If they then succeed, as so easily happens with the repressed sex-impulses, in fighting their way through—along circuitous routes—to a direct or a substitutive gratification, this success, which might otherwise have brought pleasure, is experienced by the ego as "pain." In consequence of the old conflict which ended in repression, the pleasure-principle has been violated anew, just at the moment when certain impulses were at work on the achievement of fresh pleasure in pursuance of the principle. The details of the process by which repression changes a possibility of pleasure into a source of "pain" are not yet fully understood, or are not yet capable of clear presentation, but it is certain that all neurotic "pain" is of this kind, is pleasure which cannot be experienced as such.

The two sources of "pain" here indicated still do not nearly cover the majority of our painful experiences, but as to the rest one may say with a fair show of reason that their presence does not impugn the supremacy of the pleasure-principle. Most of the "pain" we experience is of a perceptual order, perception either of the urge of unsatisfied instincts or of something in the external world which may be painful in itself or may arouse painful anticipations in the psychic apparatus and is recognized by it as *danger*. The reaction to these

<sup>2</sup> The word *Besetzung* (literally: "state of being occupied"), as in the expressions *Besetzungsenergie* and *Energiebesetzung*, has been rendered by the words "investment" and "charge," the latter being taken from the analogy of electricity.—TR.

<sup>1</sup> *Op. cit.*, p. 90.

claims of impulse and these threats of danger, a reaction in which the real activity of the psychic apparatus is manifested, may be guided correctly by the pleasure-principle or by the reality-principle which modifies this. It seems thus unnecessary to recognize a still more far-reaching limitation of the pleasure-principle, and, nevertheless, it is precisely the investigation of the psychic reaction to external danger that may supply new material and new questions in regard to the problem here treated.

## II

AFTER severe shock of a mechanical nature, railway collision, or other accident in which danger to life is involved, a condition may arise which has long been recognized and to which the name *traumatic neurosis* is attached. The terrible war that is just over has been responsible for an immense number of such maladies and, at least, has put an end to the inclination to explain them on the basis of organic injury to the nervous system due to the operation of mechanical force.<sup>1</sup> The clinical picture of traumatic neurosis approaches that of hysteria in its wealth of similar motor symptoms, but usually surpasses it in its strongly marked signs of subjective suffering—in this, resembling rather hypochondria or melancholia—and in the evidences of a far more comprehensive general weakening and shattering of the mental functions. Neither the war neuroses nor the traumatic neuroses of peace are as yet fully understood. With the war neuroses some light was contributed, but, also, on the other hand, a certain confusion introduced, by the fact that the same type of malady could occasionally occur without the interposition of gross mechanical force. In the traumatic neuroses, there are two outstanding features which might serve as clues for further reflection: first, that the chief causal factor seemed to lie in the element of surprise, in the fright; and secondly, that an injury or wound sustained at the same time generally tended to prevent the occurrence of the neurosis. *Fright, fear, apprehension* are incorrectly used as synonymous expressions: in their relation to danger they admit of quite clear distinction. Apprehension (*Angst*) denotes a certain condition as of expectation of danger and preparation for it, even though it be an unknown one; fear (*Furcht*) requires a definite object of which one is afraid; fright

(*Schreck*) is the name of the condition to which one is reduced if one encounters a danger without being prepared for it; it lays stress on the element of surprise. In my opinion, apprehension cannot produce a traumatic neurosis; in apprehension there is something which protects against fright and therefore against the fright-neurosis. We shall return later to this dictum.

The study of dreams may be regarded as the most trustworthy approach to the exploration of the deeper psychic processes. Now in the traumatic neuroses the dream life has this peculiarity: it continually takes the patient back to the situation of his disaster, from which he awakens in renewed terror. This fact has caused less surprise than it merits. The obtuseness on the patient over and again, even in sleep, of the impression made by the traumatic experience is taken as being merely a proof of its strength. The patient has, so to speak, undergone a psychical fixation as to the trauma. Fixations of this kind on the experience which has brought about the malady have long been known to us in connection with hysteria. Breuer and I stated in 1893 that hysterics suffer for the most part from reminiscences. In the war neuroses, observers, such as Ferenczi and Simmel, have been able to explain a number of motor symptoms as fixation on the factor of the trauma.

But I am not aware that the patients suffering from traumatic neuroses are much occupied in waking life with the recollection of what happened to them. They, perhaps, strive rather not to think of it. To regard it as self-evident that the dream at night takes them back to the situation which has caused the trouble is to misunderstand the nature of dreams. It would be more in correspondence with that nature if the patient were presented (in sleep) with images from the time of his normal health or of his hoped-for recovery. If we are not to go thoroughly astray as to the wish-fulfilment tendency of the dream in consequence of these dreams of the shock neuroses, perhaps the expedient is left us of supposing that in this condition the dream function suffers dislocation along with the others and is diverted from its usual ends, or else we should have to think of the enigmatic masochistic tendencies of the ego.

I propose now to leave the obscure and gloomy theme of the traumatic neuroses and to study the way in which the psychic apparatus works in one of its earliest normal activities. I refer to the play of children.

The different theories of child-play have

<sup>1</sup> Ferenczi, Abraham, Simmel, and Ernest Jones, *Psycho-Analysis and the War Neuroses*, No. 2 of the International Psycho-Analytical Library, 1921.

recently been collated by S. Pfeifer in *Imago*<sup>1</sup> and their analytical value estimated; I may here refer the reader to this work. These theories endeavour to conjecture the motives of children's play, though without placing any special stress on the *economic* point of view, i.e., consideration of the attainment of pleasure. Without the intention of making a comprehensive study of these phenomena I availed myself of an opportunity which offered of elucidating the first game invented by himself of a boy eighteen months old. It was more than a casual observation, for I lived for some weeks under the same roof as the child and his parents, and it was a considerable time before the meaning of his puzzling and continually repeated performance became clear to me.

The child was in no respect forward in his intellectual development; at eighteen months he spoke only a few intelligible words, making, besides, sundry significant sounds which were understood by those about him. But he made himself understood by his parents and the maid-servant, and had a good reputation for behaving "properly." He did not disturb his parents at night; he scrupulously obeyed orders about not touching various objects and not going into certain rooms; and above all he never cried when his mother went out and left him for hours together, although the tie to his mother was a very close one: she had not only nourished him herself, but had cared for him and brought him up without any outside help. Occasionally, however, this well-behaved child evinced the troublesome habit of flinging into the corner of the room or under the bed all the little things he could lay his hands on, so that to gather up his toys was often no light task. He accompanied this by an expression of interest and gratification, emitting a loud long-drawn-out "o-o-o-oh" which, in the judgment of the mother (one that coincided with my own), was not an interjection but meant "go away" (*fort*). I saw at last that this was a game, and that the child used all his toys only to play "being gone" (*fortsein*) with them. One day, I made an observation that confirmed my view. The child had a wooden reel with a piece of string wound round it. It never occurred to him, for example, to drag this after him on the floor and so play horse and cart with it, but he kept throwing it with considerable skill, held by the string, over the side of his little draped cot, so that the reel disappeared into it, then

said his significant "o-o-o-oh" and drew the reel by the string out of the cot again, greeting its reappearance with a joyful "*Da*" (there). This was, therefore, the complete game, disappearance and return, the first act being the only one generally observed by the onlookers, and the one untiringly repeated by the child as a game for its own sake, although the greater pleasure unquestionably attached to the second act.<sup>2</sup>

The meaning of the game was then not far to seek. It was connected with the child's remarkable cultural achievement—the foregoing of the satisfaction of an instinct—as the result of which he could let his mother go away without making any fuss. He made it right with himself, so to speak, by dramatizing the same disappearance and return with the objects he had at hand. It is, of course, of no importance for the affective value of this game whether the child invented it himself or adopted it from a suggestion from outside. Our interest will attach itself to another point. The departure of the mother cannot possibly have been pleasant for the child, nor merely a matter of indifference. How then does it accord with the pleasure-principle that he repeats this painful experience as a game? The answer will perhaps be forthcoming that the departure must be played as the necessary prelude to the joyful return, and that in this latter lay the true purpose of the game. As against this, however, there is the observation that the first act, the going away, was played by itself as a game and far more frequently than the whole drama with its joyful conclusion.

The analysis of a single case of this kind yields no sure conclusion: on impartial consideration one gains the impression that it is from another motive that the child has turned the experience into a game. He was in the first place passive, was overtaken by the experience, but now brings himself in as playing an active part, by repeating the experience as a game in spite of its unpleasing nature. This effort might be ascribed to the impulse to obtain the mastery of a situation (the *power* instinct), which remains independent of any question of whether

<sup>2</sup>This interpretation was fully established by a further observation. One day, when the mother had been out for some hours she was greeted on her return by the information "Baby o-o-o-o" which at first remained unintelligible. It soon proved that during his long, lonely hours he had found a method of bringing about his own disappearance. He had discovered his reflection in the long mirror which nearly reached to the ground and had then crouched down in front of it, so that the reflection was *fort*.

<sup>1</sup>Vol. V, 243, 1919.

the recollection was a pleasant one or not. But another interpretation may be attempted. The flinging away of the object so that it is gone might be the gratification of an impulse of revenge suppressed in real life but directed against the mother for going away, and would then have the defiant meaning: "Yes, you can go, I don't want you, I am sending you away myself." The same child, a year later than my observations, used to throw on the floor a toy which displeased him, and to say "Go to the war!" He had been told that his absent father was at the war, and he did not miss him at all, giving the clearest indications that he did not wish to be disturbed in the sole possession of his mother.<sup>1</sup> It is known of other children also that they can give vent to similar hostile feelings by throwing objects away in place of people.<sup>2</sup> Thus, one is left in doubt whether the compulsion to work over in psychic life what has made a deep impression, to make oneself fully master of it, can express itself primarily and independently of the pleasure-principle. In the case discussed here, however, the child might have repeated a disagreeable impression in play only because with the repetition was bound up a pleasure gain of a different kind but more direct.

Nor does the further pursuit of the question of play resolve our hesitations between two conceptions. We see that children repeat in their play everything that has made a great impression on them in actual life, that they thereby ab-react the strength of the impression and so to speak make themselves masters of the situation. But on the other hand, it is clear enough that all their play is influenced by the dominant wish of their time of life: viz., to be grown-up and to be able to do what grown-up people do. It is also observable that the unpleasing character of the experience does not always prevent its being utilized as a game. If a doctor examines a child's throat, or performs a small operation on him, the alarming experience will quite certainly be made the subject of the next game, but in this the pleasure gain from another source is not to be overlooked. In passing from the passivity of experience to the activity of play the child applies to his playfellow the unpleasant occurrence

that befell himself and so avenges himself on the person of this proxy.

From this discussion, it is at all events evident that it is unnecessary to assume a particular imitation impulse as the motive of play. We may add the reminder that the dramatic and imitative art of adults, which differs from the behaviour of children in being directed towards the spectator, does not, however, spare the latter the most painful impressions, e.g., in tragedy, and yet can be felt by him as highly enjoyable. This convinces us that even under the domination of the pleasure-principle there are ways and means enough of making what is in itself disagreeable the object of memory and of psychic preoccupation. A theory of aesthetics with an economic point of view should deal with these cases and situations ending in final pleasure gain: for our purposes, they are of no help, since they presuppose the existence and supremacy of the pleasure-principle and bear no witness to the operation of tendencies beyond the pleasure-principle, that is to say, tendencies which might be of earlier origin and independent of this.

### III

FIVE-AND-TWENTY years of intensive work have brought about a complete change in the more immediate aims of psycho-analytic technique. At first the endeavours of the analytic physician were confined to divining the unconscious of which his patient was unaware, effecting a synthesis of its various components, and communicating it at the right time. Psycho-analysis was above all an art of interpretation. Since the therapeutic task was not thereby accomplished, the next aim was to compel the patient to confirm the reconstruction through his own memory. In this endeavour, the chief emphasis was on the resistances of the patient; the art now lay in unveiling these as soon as possible, in calling the patient's attention to them, and by human influence—here came in suggestion acting as *transference*—teaching him to abandon the resistances.

It then became increasingly clear however, that the aim in view, the bringing into consciousness of the unconscious, was not fully attainable by this method either. The patient cannot recall all of what lies repressed, perhaps not even the essential part of it, and so gains no conviction that the conclusion presented to him is correct. He is obliged rather to *repeat* as a current experience what is repressed, instead of, as the physician would prefer to see

<sup>1</sup> When the child was five and three-quarter years old his mother died. Now, when she was really *gone* (o-o-o), the boy showed no grief for her. A second child had, it is true, been born in the meantime and had aroused his strongest jealousy.

<sup>2</sup> See "A Childhood-Memory from *Dichtung und Wahrheit*," in *Collected Papers*, IV.

him do, *recollecting* it as a fragment of the past.<sup>1</sup> This reproduction appearing with unwelcome fidelity always contains a fragment of the infantile sex-life, therefore of the Oedipus complex and its off-shoots, and is played regularly in the sphere of transference, i.e., the relationship to the physician. When this point in the treatment is reached, it may be said that the earlier neurosis is now replaced by a fresh one, viz., the transference-neurosis. The physician makes it his concern to limit the scope of this transference-neurosis as much as he can, to force into memory as much as possible, and to leave as little as possible to repetition. The relation established between memory and reproduction is different for every case. As a rule, the physician cannot spare the patient this phase of the cure; he must let him live through a certain fragment of his forgotten life, and has to see to it that some measure of ascendancy remains, in the light of which the apparent reality is always recognized as a reflection of a forgotten past. If this is successfully accomplished, then conviction on the part of the patient is attained, and with it the therapeutic result that depends on it.

In order to render more comprehensible this *repetition-compulsion* which appears in the psycho-analytic treatment of neurotics, we must above all get entirely rid of the erroneous idea that in this struggle with resistances we are concerned with any resistance on the part of the unconscious. The unconscious, i.e., the *repressed* material, offers no resistance whatever to the curative efforts; indeed it has no other aim than to force its way through the pressure weighing on it, either to consciousness or to discharge by means of some real action. The resistance in the treatment proceeds from the same higher levels and systems in the psychic life that in their time brought about the repression. But since the motives of the resistances, and indeed the resistances themselves, are found in the process of the treatment to be unconscious, we are well advised to amend an inadequacy in our mode of expression. We escape ambiguity if we contrast not the conscious and the unconscious, but the coherent ego and the repressed. Much in the ego is certainly unconscious itself, just what may be called the kernel of the ego; only a part of it comes under the category of *preconscious*. After thus replacing a purely descriptive method of expression

by a systematic or dynamic one, we may say that the resistance on the part of the analysed person proceeds from his ego, and then we at once see that the *repetition-compulsion* must be ascribed to the repressed element in the unconscious. It probably could not find expression till the work of the treatment coming to meet it had loosened the repression.

There is no doubt that the resistance of the conscious and preconscious ego subserves the pleasure-principle; it is trying to avoid the "pain" that would be aroused by the release of the repressed material, and our efforts are directed to effecting an entry for such painful feeling by an appeal to the reality-principle. In what relation to the pleasure-principle, then, does the repetition-compulsion stand, that which expresses the force of what is repressed? It is plain that most of what is revived by the repetition-compulsion cannot but bring discomfort to the ego, for it promotes the bringing to light of the activities of repressed impulses; but that is a discomfort we have already taken into account and without subversion of the pleasure-principle, since it is "pain" in respect of one system and at the same time satisfaction for the other. The new and remarkable fact, however, that we have now to describe is that the repetition-compulsion also revives experiences of the past that contain no potentiality of pleasure, and which could at no time have been satisfactions, even of impulses since repressed.

The efflorescence of infantile sex-life was, by reason of the irreconcilability of its wishes with reality and the inadequacy of the childhood stage of development reached, destined to pass away. It perished in most painful circumstances and with feelings of a deeply distressing nature. Loss and failure in the sphere of the affections left behind on the ego-feeling marks of injury comparable to a narcissistic scar, which, according to my experience and the exposition given by Marcinowski,<sup>2</sup> yields the most important contribution to the *inferiority complex* common among neurotics. The sex-quest to which the physical development of the child set limits could be brought to no satisfying conclusion; hence the plaint in later life: "I can't do anything, I am never successful." The bonds of tenderness linking the child more especially to the parent of the opposite sex succumbed to disappointment, to the vain expectation of sat-

<sup>1</sup> See "Further Recommendations in the Technique of Psycho-Analysis, II: Recollection, Repetition, and Working-Through," *Collected Papers*, II.

<sup>2</sup> Marcinowski, "Die erotischen Quellen der Minderwertigkeitsgefühle," *Zeitschrift für Sexualwissenschaft*, 1918, IV.

isfaction, and to the jealousy aroused by the birth of a new child, unmistakable proof as it is of the faithlessness of the loved parent; the child's attempt, undertaken with tragic seriousness, to produce another such child himself met with humiliating failure; while the partial withdrawal of the tenderness lavished on the little one, the more exacting demands of discipline and education, severe words and an occasional punishment finally revealed to him the whole extent of the disdain which is his portion. Some few regularly recurring types are to be found, according to the way in which the typical love of this period was brought to an end.

All these undesired happenings and painful affective situations are repeated by neurotics in the *transference* stage and re-animated with much ingenuity. They struggle to break off the unfinished treatment, they know how to recreate the feeling of being disdained, how to force the physician to adopt brusque speech and a chilling manner towards them, they find suitable objects for their jealousy, they substitute for the ardently desired child of early days the promise of some great gift which becomes as little real as that was. Nothing of all this could ever have afforded any pleasure; one would suppose it ought to bring somewhat less "pain" if revealed as memory rather than if lived through as a new experience. It is a question naturally of the action of impulses that should lead to satisfaction, but the experience that instead of this they even then brought "pain" has borne no result. The act is repeated in spite of everything; a powerful compulsion insists on it.

That which psycho-analysis reveals in the transference phenomena with neurotics can also be observed in the life of normal persons. It here gives the impression of a pursuing fate, a demonic trait in their destiny, and psycho-analysis has from the outset regarded such a life history as in a large measure self-imposed and determined by infantile influences. The compulsion which thereby finds expression is in no way different from the repetition-compulsion of neurotics, even though such persons have never shown signs of a neurotic conflict resulting in symptoms. Thus one knows people with whom every human relationship ends in the same way: benefactors whose protégés, however different they may otherwise have been, invariably after a time desert them in ill-will, so that they are apparently condemned to drain to the dregs all the bitterness of ingratitude; men with whom every friendship

ends in the friend's treachery; others who indefinitely often in their lives invest some other person with authority either in their own eyes or generally, and themselves overthrow such authority after a given time, only to replace it by a new one; lovers whose tender relationships with women each and all run through the same phases and come to the same end, and so on. We are less astonished at this "endless repetition of the same" if there is involved a question of active behaviour on the part of the person concerned, and if we detect in his character an unalterable trait which must always manifest itself in the repetition of identical experiences. Far more striking are those cases where the person seems to be experiencing something passively, without exerting any influence of his own, and yet always meets with the same fate over and over again. One may recall, for example, the story of the woman who married three men in succession, each of whom fell ill after a short time and whom she had to nurse till their death.<sup>1</sup> Tasso gives a singularly affecting poetical portrayal of such a trend of fate in the romantic epic, *Gerusalemme Liberta*. The hero, Tancred, has unwittingly slain Clorinda, the maiden he loved, who fought with him disguised in the armour of an enemy knight. After her burial he penetrates into the mysterious enchanted wood, the bane of the army of the crusaders. Here he hews down a tall tree with his sword, but from the gash in the trunk blood streams forth and the voice of Clorinda, whose soul is imprisoned in the trees, cries out to him in reproach that he has once more wrought a baleful deed on his beloved.

In the light of such observations as these, drawn from the behaviour during transference and from the fate of human beings, we may venture to make the assumption that there really exists in psychic life a repetition-compulsion, which goes beyond the pleasure-principle. We shall now also feel disposed to relate to this compelling force the dreams of shock-patients and the play-impulse in children. We must, of course, remind ourselves that only in rare cases can we recognize the workings of this repetition-compulsion in a pure form, without the co-operation of other motives. As regards children's play, we have already pointed out what other interpretations its origin permits. The repetition-compulsion and direct

<sup>1</sup> See the pertinent observations of C. G. Jung in his article, "Die Bedeutung des Vaters für das Schicksal des Einzelnen," *Jahrbuch für psychoanal. u. psychopath. Forschungen*, 1901, Vol. I.

pleasurable satisfaction of impulse seem there to be inextricably intertwined. The transference phenomena obviously subserve the purpose of the resistance made by the ego persisting in its repression: the repetition-compulsion is, as it were, called to the aid of the ego, which is resolved to hold fast to the pleasure-principle. In what one might call the destiny-compulsion much appears capable of rational explanation, so that no need is felt to establish a new and mysterious impulse. The least suspicious case is perhaps that of the shock-dream, but on closer examination it must be admitted that in the other examples, too, the state of affairs is not completely explained by the operation of the motives known to us. There remains enough over to justify the assumption of a repetition-compulsion, and this seems to us more primitive, more elementary, more instinctive than the pleasure-principle which is displaced by it. But if there is such a repetition-compulsion in psychic life, we should naturally like to know with what function it corresponds, under what conditions it may appear, and in what relation it stands to the pleasure-principle, to which we have heretofore ascribed the domination over the course of the processes of excitation in the psychic life.

#### IV

WHAT follows now is speculation, speculation often far-fetched, which each will, according to his particular attitude, acknowledge or neglect. Or one may call it the exploitation of an idea out of curiosity to see whither it will lead.

Psycho-analytic speculation starts from the impression gained on investigating unconscious processes that consciousness cannot be the most general characteristic of psychic processes, but merely a special function of them. Metapsychologically expressed, it asserts that consciousness is the functioning of a particular system which may be called *Bw*. Since consciousness essentially yields perceptions of excitations coming from without and feeling (*Empfindungen*) of pleasure and "pain" which can only be derived from within the psychic apparatus, we may allot the system *W-Bw*<sup>1</sup> (= perceptual consciousness) a position in space. It must lie on the boundary between outer and inner, must face towards the outer world, and must envelop the other psychic systems. We then note that in this assumption we have ventured nothing new, but are in agreement with the localizing

tendencies of cerebral anatomy, which places the *seat* of consciousness in the cortical layer, the outermost enveloping layer of the central organ. Cerebral anatomy does not need to wonder why—anatomically speaking—consciousness should be accommodated on the surface of the brain, instead of being safely lodged somewhere in the deepest recesses of it. Perhaps we may carry matters a little further than this in our deduction of such a position for our system *W-Bw*.

Consciousness is not the only peculiar feature that we ascribe to the processes in this system. Our impressions gained by psycho-analytic experience lead us to the supposition that all excitation processes in the other systems leave in them permanent traces forming the foundations of memory-records which have nothing to do with the question of becoming conscious. They are often strongest and most enduring when the process that left them behind never reached consciousness at all. But we find it difficult to believe that such lasting traces of excitation are formed also in the system *W-Bw* itself. If they remained permanently in consciousness, they would very soon limit the fitness of the system for registration of new excitations;<sup>2</sup> on the other hand, if they became unconscious, we should be confronted with the task of explaining the existence of unconscious processes in a system whose functioning is otherwise accompanied by the phenomenon of consciousness. We should, so to speak, have gained nothing and altered nothing by our supposition which relegates to a special system the process of becoming conscious. Though this may not be an absolutely binding consideration, it may, at any rate, lead us to conjecture that becoming conscious and leaving behind a memory-trace are processes incompatible with each other in the same system. We should thus be able to say: in the system *Bw*, the process of excitation becomes conscious, but it leaves behind no lasting trace; all the traces of it on which memory relies would come about in the next systems inwards from the propagation of the excitation on to them. It is on these lines that the scheme is sketched which I inserted into the speculative section of my *Interpretation of Dreams* in 1900. If one reflects how little we know from other sources about the origin of consciousness, the pronouncement that *consciousness arises in*

<sup>1</sup> Thus named after the German words *Wahrnehmung* (=perception) and *Bewusstsein* (=consciousness).—TR.

<sup>2</sup> Here I follow throughout J. Breuer's exposition in the theoretical section of the *Studien über Hysterie*, 1895.

the place of the memory-trace must be conceded at least the importance of a statement which is to some extent definite.

The system *Bw* would thus be characterized by the peculiarity that the excitation process does not leave in it, as it does in all other psychic systems, a permanent alteration of its elements, but is, as it were, discharged in the phenomenon of becoming conscious and vanishes. Such a departure from the general rule requires an explanation on the ground of a factor which comes into account in this one system only: this factor which is absent from all other systems might well be the exposed situation of the *Bw* system—its immediate contact with the outer world.

Let us imagine the living organism in the simplest possible form as an undifferentiated vesicle of sensitive substance: then its surface, exposed as it is to the outer world, is by its very position differentiated and serves as an organ for receiving stimuli. Embryology, repeating as it does the history of evolution, does, in fact, show that the central nervous system arises from the ectoderm; the grey cortex of the brain remains a derivative of the primitive superficial layer and may have inherited essential properties from this. It would then be easily conceivable that, owing to the constant impact of external stimuli on the superficies of the vesicle, its substance would undergo lasting alteration to a certain depth, so that its excitation process takes a different course from that taken in the deeper layers. Thus, a rind would be formed which would finally have been so burned through by the effects of stimulation that it presents the most favourable conditions for the reception of stimuli and is incapable of any further modification. Applying this idea to the system *Bw*, this would mean that its elements are not susceptible of any further lasting alteration from the passage of the excitation, because they are already modified to the uttermost in that respect. But they are then capable of giving rise to consciousness. In what exactly these modifications of the substance and of the excitation process in it consist many views may be held which as yet cannot be tested. It may be assumed that the excitation has, in its transmission from one element to another, to overcome a resistance, and that this diminution of the resistance itself lays down the permanent trace of the excitation (a path): in system *Bw*, there would no longer exist any such resistance to transmission from one element to another. We

may associate with this conception Breuer's distinction between quiescent (bound) and free-moving *investment-energy* in the elements of the psychic systems;<sup>1</sup> the elements of the system *Bw* would then convey no *bound* energy, only free energy capable of discharge. In my opinion, however, it is better for the present to express oneself as to these conditions in the least committal way. At any rate, by these speculations we should have brought the origin of consciousness into a certain connection with the position of the system *Bw* and with the peculiarities of the excitation process to be ascribed to this.

We have more to say about the living vesicle with its receptive outer layer. This morsel of living substance floats about in an outer world which is charged with the most potent energies, and it would be destroyed by the operation of the stimuli proceeding from this world if it were not furnished with a protection against stimulation (*Reizschutz*). It acquires this through its outermost layer—which gives the structure that belongs to living matter—becoming in a measure inorganic, and this now operates as a special integument or membrane that keeps off the stimuli, i.e., makes it impossible for the energies of the outer world to act with more than a fragment of their intensity on the layers immediately below which have preserved their vitality. These are now able under cover of the protecting layer to devote themselves to the reception of those stimulus masses that have been let through. But the outer layer has by its own death secured all the deeper layers from a like fate—at least, so long as no stimuli present themselves of such a strength as to break through the protective barrier. For the living organism, protection against stimuli is almost a more important task than reception of stimuli; the protective barrier is equipped with its own store of energy and must above all endeavour to protect the special forms of energy-transformations going on within itself from the equalising and, therefore, destructive influence of the enormous energies at work in the outer world. The reception of stimuli serves above all the purpose of collecting information about the direction and nature of the external stimuli, and for that it must suffice to take little samples of the outer world, to taste it, so to speak, in small quantities. In highly developed organisms the receptive external layer of what was once a vesicle has long been withdrawn into the depths of the

<sup>1</sup> J. Breuer and S. Freud, *Studien über Hysterie*.

body, but portions of it have been left on the surface immediately beneath the common protective barrier. These portions form the sense organs, which essentially comprise arrangements for the reception of specific stimuli, but also possess special arrangements adapted for a fresh protection against an overwhelming amount of stimulus, and for warding off unsuitable kinds of stimuli. It is characteristic of them that they assimilate only very small quantities of the outer stimulus, and take in only samples of the outer world; one might compare them to antennae which touch at the outer world and then constantly withdraw from it again.

At this point, I shall permit myself to touch cursorily upon a theme which would deserve the most thorough treatment. The Kantian proposition that time and space are necessary modes of thought may be submitted to discussion today in the light of certain knowledge reached through psycho-analysis. We have found by experience that unconscious mental processes are in themselves *timeless*. That is to say, to begin with: they are not arranged chronologically, time alters nothing in them, nor can the idea of time be applied to them. These are negative characteristics, which can be made plain only by instituting a comparison with conscious psychic processes. Our abstract conception of time seems rather to be derived wholly from the mode of functioning of the system *W-Bw*, and to correspond with a self-perception of it. In this mode of functioning of the system, another form of protection against stimulation probably comes into play. I know that these statements sound very obscure, but I must confine myself to these few hints.

So far we have got to the point that the living vesicle is equipped with a protection against stimuli from the outer world. Before that, we had decided that the cortical layer next to it must be differentiated as the organ for reception of external stimuli. But this sensitive layer (what is later the system *Bw*) also receives excitations from within: the position of the system between outer and inner and the difference in the conditions under which this receptivity operates on the two sides become deciding factors for the functioning of the system and of the whole psychic apparatus. Towards the outer world there is a barrier against stimuli, and the mass of excitations coming up against it will take effect only on a reduced scale; towards what is within, no protection against stimuli is possible; the excitations of the deeper layers

pursue their way direct and in undiminished mass into the system, while certain characteristics of their course produce the series of pleasure-pain feelings. Naturally, the excitations coming from within will, in conformity with their intensity and other qualitative characteristics (or possibly their amplitude), be more proportionate to the mode of operation of the system than the stimuli streaming in from the outer world. Two things are, however, decisively determined by these conditions: first, the preponderance over all outer stimuli of the pleasure and "pain" feelings, which are an index for processes within the mechanism; and, secondly, a shaping of behaviour towards such inner excitations as bring with them an overplus of "pain." There will be a tendency to treat them as though they were acting not from within but from without, in order for it to be possible to apply against them the defensive measures of the barrier against stimuli (*Reizschutz*). This is the origin of projection, for which so important a part is reserved in the production of pathological states.

I have the impression that by these last considerations we have approached nearer to a comprehension of the supremacy of the pleasure-principle, but we have not attained to an explanation of those cases which are opposed to it. Let us, therefore, go a step further. Such external excitations as are strong enough to break through the barrier against stimuli we call *traumatic*. In my opinion, the concept of trauma involves such a relationship to an otherwise efficacious barrier. An occurrence such as an external trauma will undoubtedly provoke a very extensive disturbance in the workings of the energy of the organism, and will set in motion every kind of protective measure. But the pleasure-principle is, to begin with, put out of action here. The flooding of the psychic apparatus with large masses of stimuli can no longer be prevented: on the contrary, another task presents itself—to bring the stimulus under control, to *bind* in the psyche the stimulus mass that has broken its way in, so as to bring about a discharge of it.

Probably, the specific discomfort of bodily pain is the result of some local breaking through of the barrier against stimuli. From this point in the periphery there stream to the central psychic apparatus continual excitations such as would otherwise come only from within.<sup>1</sup> What are we to expect as the reaction of the

<sup>1</sup> See the paper *Instincts and their Vicissitudes*, p. 412 above.

psychic life to this invasion? From all sides the *charging energy* is called on in order to create all round the breach correspondingly high *charges* of energy. An immense *counter-charge* is set up, in favour of which all the other psychic systems are impoverished, so that a wide-spread paralysis or diminution of other psychic activity follows. We endeavour to learn from examples such as these to base our metapsychological conjectures on such prototypes. Thus, from this behaviour we draw the conclusion that even a highly charged system is able to receive new energy streaming in, to convert it into a *quiescent charge*, thus to *bind* it psychically. The more intense is the intrinsic quiescent charge, the greater is its binding force: and, conversely, the lower the charge of the system, the less capable is it of receiving the energy that streams in, and so the more violent are the consequences when the barrier against stimuli is broken through. It is not a valid objection to this view that the intensifying of the charges round the place of irruption could be much more simply explained as the direct action of the oncoming mass of excitation. If that were so, the psychic apparatus would merely undergo an increase of its energy charges, and the paralyzing character of pain, with the impoverishment of all the other systems, would remain without explanation. Nor do the very violent discharge effects of pain invalidate our explanation, for they happen in a reflex manner, that is to say, they follow without the interposition of the psychic apparatus. The indefinite nature of all the discussions that we term *metapsychological* naturally comes from the fact that we know nothing about the nature of the excitation process in the elements of the psychic systems and do not feel justified in making any assumption about it. Thus we are all the time operating with a large X, which we carry over into every new formula. That this process is accomplished with energies which differ quantitatively is an easily admissible postulate; that it also has more than one quality (e.g., in the direction of amplitude) may be regarded as probable: the new consideration we have brought in is Breuer's proposition that we have to do with two ways in which a system may be filled with energy, so that a distinction has to be made between a *charging* of the psychic systems (or its elements) that is free-flowing and striving to be discharged and one that is quiescent. Perhaps we may admit the conjecture that the binding of the energy streaming into the psychic ap-

paratus consists in a translating of it from the free-flowing to the quiescent state.

I think one may venture (tentatively) to regard the ordinary traumatic neurosis as the result of an extensive rupture of the barrier against stimuli. In this way the old naïve doctrine of *shock* would come into its own again, apparently in opposition to a later and psychologically more pretentious view which ascribes aetiological significance not to the effect of the mechanical force, but to the fright and the menace to life. But these opposing views are not irreconcilable, and the psycho-analytic conception of the traumatic neurosis is far from being identical with the crudest form of the *shock* theory. While the latter takes the essential nature of the shock as residing in the direct injury to the molecular structure, or even to the histological structure, of the nervous elements, we seek to understand the effect of the shock by considering the breaking through of the barrier with which the psychic organ is provided against stimuli, and from the tasks with which this is thereby faced. Fright retains its meaning for us too. What conditions it is the failure of the mechanism of apprehension to make the proper preparation, including the over-charging of the systems first receiving the stimulus. In consequence of this lower degree of charging, these systems are hardly in a position to bind the oncoming masses of excitation, and the consequences of the breaking through of the protective barrier appear all the more easily. We thus find that the apprehensive preparation, together with the over-charging of the receptive systems, represents the last line of defence against stimuli. For a great number of traumata, the difference between the unprepared systems and those prepared by over-charging may turn the scale as to the outcome: with a trauma beyond a certain strength, such a difference may no longer be of any importance. When the dreams of patients suffering from traumatic neuroses so regularly take them back to the situation of the disaster, they do not thereby, it is true, serve the purpose of wish-fulfilment, the hallucinatory conjuring up of which has, under the domination of the pleasure-principle, become the function of dreams. But we may assume that they thereby subserve another purpose, which must be fulfilled before the pleasure-principle can begin its sway. These dreams are attempts at restoring control of the stimuli by developing apprehension, the pretermission of which caused the traumatic neurosis. They thus afford us an in-

sight into a function of the psychic apparatus, which without contradicting the pleasure-principle is nevertheless independent of it, and appears to be of earlier origin than the aim of attaining pleasure and avoiding "pain."

This is, therefore, the moment to concede for the first time an exception to the principle that the dream is a wish-fulfilment. Anxiety dreams are no such exception, as I have repeatedly and in detail shown; nor are the *punishment dreams*, for they merely put in the place of the interdicted wish-fulfilment the punishment appropriate to it, and are thus the wish-fulfilment of the sense of guilt reacting on the condemned impulse. But the dreams mentioned above of patients suffering from traumatic neuroses do not permit of classification under the category of wish-fulfilment, nor do the dreams occurring during psycho-analysis that bring back the recollection of the psychic traumata of childhood. They obey rather the repetition-compulsion, which in analysis, it is true, is supported by the (not unconscious) wish to conjure up again what has been forgotten and repressed. Thus, the function of the dream, viz., to do away with the motives leading to interruption of sleep by presenting wish-fulfilments of the disturbing excitations, would not be its original one; the dream could secure control of this function only after the whole psychic life had accepted the domination of the pleasure-principle. If there is a *beyond the pleasure-principle*, it is logical to admit a prehistoric past also for the wish-fulfilling tendency of the dream, though to do so is no contradiction of its later function. Now, when this tendency is once broken through, there arises the further question: are such dreams, which in the interests of the psychical binding of traumatic impressions follow the repetition-compulsion, not possible apart from analysis? The answer is certainly in the affirmative.

With regard to the war neuroses, so far as the term has any significance apart from a reference to the occasion of the appearance of the illness, I have explained elsewhere that they might very well be traumatic neuroses which have arisen the more easily on account of an ego-conflict.<sup>1</sup> The fact mentioned on page 641, viz., that a severe injury inflicted at the same time by the trauma lessens the chance of a neurosis arising, is no longer difficult to understand if two circumstances emphasised by psy-

cho-analytic research are borne in mind. First, that mechanical concussion must be recognized as one of the sources of sexual excitation;<sup>2</sup> and, secondly, that a painful and feverish illness exerts for the time it lasts a powerful influence on the distribution of the libido. Thus, the mechanical force of the trauma would set free the quota of sexual excitation which, in consequence of the lacking preparation by apprehension, has a traumatic effect: but, on the other hand, the contemporaneous bodily injury would bind the surplus excitation by the putting in of a claim to a narcissistic over-charging of the injured part.<sup>3</sup> It is also known, though the idea has not been sufficiently made use of in the Libido theory, that disturbances in the distribution of the libido so severe as those of melancholia may be removed for a time by an intercurrent organic disease; in fact even the condition of a fully developed *dementia praecox* is capable of a transitory improvement in these circumstances.

## V

THE fact that the sensitive cortical layer has no protective barrier against excitations emanating from within will have one inevitable consequence: viz., that these transmissions of stimuli acquire increased economic significance and frequently give rise to economic disturbances comparable to the traumatic neuroses. The most prolific sources of such inner excitations are the so-called *instincts* of the organism, the representatives of all forces arising within the body and transmitted to the psychic apparatus—the most important and most obscure element in psychological research.

Perhaps we shall not find it too rash an assumption that the excitations proceeding from the instincts do not conform to the type of the *bound* but of the free-moving nerve processes that are striving for discharge. The most trustworthy knowledge we have of these processes comes from the study of dreams. There we found that the processes in the unconscious systems are fundamentally different from those in the (pre)conscious; that in the unconscious *charges* may easily be completely transferred, displaced or condensed, while if this happened with preconscious material only defective results would be obtained. This is the reason for the well-known peculiarities of the manifest dream, after the preconscious residues of the

<sup>1</sup> *Psycho-Analysis and the War Neuroses*, Introduction, International Psycho-Analytical Library, No. 2, 1921.

<sup>2</sup> See the remarks: "The effects of swinging and railway travelling," in *Three Contributions to the Theory of Sex*.

<sup>3</sup> See *On Narcissism: an Introduction*, p. 399 above.

day before have undergone elaboration according to the laws of the unconscious. I termed this kind of process in the unconscious the psychic *primary process* in contradistinction to the secondary process valid in our normal waking life. Since the excitations of instincts all affect the unconscious systems, it is scarcely an innovation to say that they follow the lines of the primary process, and little more so to identify the psychic primary process with the freely mobile charge, the secondary process with changes in Breuer's bound or tonic charge.<sup>1</sup> It would then be the task of the higher layers of the psychic apparatus to bind the instinct-excitation that reaches the primary process. The failure to effect this binding would evoke a disturbance analogous to the traumatic neuroses; it is only after the binding had been successfully accomplished that the pleasure-principle (and its modification the reality-principle) would have an opportunity to assert its sway without hindrance. Till then, the other task of the psychic apparatus would take precedence, viz., to obtain control of or to bind the excitation, not in opposition to the pleasure principle but independently of it and, in part, without regard to it.

The expressions of a repetition-compulsion which we have described, both in the early activities of infantile psychic life and in the experiences of psycho-analytic treatment, show in a high degree an instinctive character, and, where they come into contrast with the pleasure-principle, a demonic character. In the play of children, we seem to arrive at the conclusion that the child repeats even the unpleasant experiences because through his own activity he gains a far more thorough mastery of the strong impression than was possible by mere passive experience. Every fresh repetition seems to strengthen this mastery for which the child strives; even with pleasurable experiences the child cannot do enough in the way of repetition and will inexorably insist on the identity of the impression. This characteristic is destined later to disappear. A witticism heard for the second time will almost fail of effect; a theatrical performance will never make the same impression the second time that it did on the first occasion; indeed, it is hard to persuade the adult to read again at all soon a book he has enjoyed. Novelty is always the necessary condition of enjoyment. The child, however, never gets tired of demanding from a grown-up the repetition of a game he has played with him before or has

shown him, till at last the grown-up refuses, utterly worn out; similarly, if he has been told a pretty story, he wants always to hear the same story instead of a new one, insists inexorably on exact repetition and corrects each deviation which the narrator lets slip by mistake, which, perhaps, he even thought to gain new merit by inserting. Here, there is no contradiction of the pleasure-principle: it is evident that the repetition, the rediscovery of the identity, is itself a source of pleasure. In the case of a patient in analysis, on the other hand, it is plain that the compulsion to repeat in the transference the occurrences of his infantile life disregards in every way the pleasure-principle. The patient behaves in this respect completely like a child, and thus makes it clear to us that the repressed memory-traces of his primitive experience are not present in a *bound* form, are indeed, in a sense, not capable of the secondary process. To this fact of their not being bound they owe their power to weave a wish phantasy that will be represented in a dream, by adhering to the residues from waking experiences. We frequently encounter the same repetition-compulsion as a therapeutic obstacle, when at the end of the treatment we wish to bring about complete detachment from the physician; and it may be supposed that the vague dread with which those who are unfamiliar with it view analysis, as though they feared to wake what they think is better left to sleep, is at root a fear of the appearance of this demonic compulsion.

In what way is the instinctive connected with the compulsion to repetition? At this point, the idea is forced upon us that we have stumbled on the trace of a general and hitherto not clearly recognized—or at least not expressly emphasized—characteristic of instinct, perhaps of all organic life. According to this, *an instinct would be a tendency innate in living organic matter impelling it towards the reinstatement of an earlier condition*, one which it had to abandon under the influence of external disturbing forces—a kind of organic elasticity, or, to put it another way, the manifestation of inertia in organic life.<sup>2</sup>

This conception of instinct strikes us as strange, since we are accustomed to see in instinct the factor urging towards change and development, and now we find ourselves required to recognize in it the very opposite, viz., the

<sup>1</sup> See "Psychology of the Dream-Processes," Section VII, in my *Interpretation of Dreams* (p. 340 above).

<sup>2</sup> I have little doubt that similar conjectures about the nature of instinct have been already repeatedly put forward.

expression of the conservative nature of living beings. On the other hand, we soon think of those examples in animal life which appear to confirm the idea of instinct having been historically conditioned. When certain fish undertake arduous journeys at spawning-time, in order to deposit the spawn in certain definite waters far removed from their usual habitats, according to the interpretation of many biologists they are only seeking the earlier homes of their kind, which in course of time they have exchanged for others. The same is said to be true of the migratory flights of birds of passage, but the search for further examples becomes superfluous when we remember that in the phenomena of heredity and in the facts of embryology we have the most imposing proofs of the organic compulsion to repetition. We see that the germ cell of a living animal is obliged to repeat in its development—although in a fleeting and curtailed fashion—the structures of all the forms from which the animal is descended, instead of hastening along the shortest path to its own final shape. A mechanical explanation of this except in some trifling particulars is impossible, and the historical explanation cannot be disregarded. In the same way, we find extending far upwards in the animal kingdom a power of reproduction whereby a lost organ is replaced by the growth of a new one exactly like it.

The obvious objection, that it may well be that besides the conservative instincts compelling repetition there are others which press towards new formation and progress, should certainly not be left unnoticed; it will be considered at a later stage of our discussion. But we may first be tempted to follow to its final consequences the hypothesis that all instincts have as their aim the reinstatement of an earlier condition. If what results gives an appearance of *profundity* or bears a resemblance to mysticism, still we know ourselves to be clear of the reproach of having striven after anything of the sort. We are in search of sober results of investigation or of reflections based upon it, and the only character we wish for in these results is that of certainty.

If, then, all organic instincts are conservative, historically acquired, and are directed towards regression, towards reinstatement of something earlier, we are obliged to place all the results of organic development to the credit of external, disturbing, and distracting influences. The rudimentary creature would from its very beginning not have wanted to change,

would, if circumstances had remained the same, have always merely repeated the same course of existence. But in the last resort it must have been the evolution of our earth, and its relation to the sun, that has left its imprint on the development of organisms. The conservative organic instincts have absorbed every one of these enforced alterations in the course of life and have stored them for repetition; they thus present the delusive appearance of forces striving after change and progress, while they are merely endeavouring to reach an old goal by ways both old and new. This final goal of all organic striving can be stated too. It would be counter to the conservative nature of instinct if the goal of life were a state never hitherto reached. It must rather be an ancient starting point, which the living being left long ago, and to which it harks back again by all the circuitous paths of development. If we may assume as an experience admitting of no exception that everything living dies from causes within itself, and returns to the inorganic, we can only say "*The goal of all life is death,*" and, casting back, "*The inanimate was there before the animate.*"

At one time or another, by some operation of force which still completely baffles conjecture, the properties of life were awakened in lifeless matter. Perhaps the process was a prototype resembling that other one which later in a certain stratum of living matter gave rise to consciousness. The tension then aroused in the previously inanimate matter strove to attain an equilibrium; the first instinct was present, that to return to lifelessness. The living substance at that time had death within easy reach; there was probably only a short course of life to run, the direction of which was determined by the chemical structure of the young organism. So through a long period of time the living substance may have been constantly created anew, and easily extinguished, until decisive external influences altered in such a way as to compel the still surviving substance to ever greater deviations from the original path of life, and to ever more complicated and circuitous routes to the attainment of the goal of death. These circuitous ways to death, faithfully retained by the conservative instincts, would be neither more nor less than the phenomena of life as we now know it. If the exclusively conservative nature of the instincts is accepted as true, it is impossible to arrive at any other suppositions with regard to the origin and goal of life.

If these conclusions sound strangely in our ears, equally so will those we are led to make concerning the great groups of instincts which we regard as lying behind the vital phenomena of organisms. The postulate of the self-preservative instincts we ascribe to every living being stands in remarkable contrast to the supposition that the whole life of instinct serves the one end of bringing about death. The theoretic significance of the instincts of self-preservation, power, and self-assertion, shrinks to nothing, seen in this light; they are part-instincts designed to secure the path to death peculiar to the organism and to ward off possibilities of return to the inorganic other than the immanent ones, but the enigmatic struggle of the organism to maintain itself in spite of all the world, a struggle that cannot be brought into connection with anything else, disappears. It remains to be added that the organism is resolved to die only in its own way; even these watchmen of life were originally the myrmidons of death. Hence, the paradox comes about that the living organism resists with all its energy influences (dangers) which could help it to reach its life-goal by a short way (a short circuit, so to speak); but this is just the behaviour that characterizes a pure instinct as contrasted with an intelligent striving.

But we must bethink ourselves: this cannot be the whole truth. The sexual instincts, for which the theory of the neuroses claims a position apart, lead us to quite another point of view. Not all organisms have yielded to the external compulsion driving them to an ever further development. Many have succeeded in maintaining themselves on their low level up to the present time: there are in existence to-day, if not all, at all events many forms of life that must resemble the primitive stages of the higher animals and plants. And, similarly, not all the elementary organisms that make up the complicated body of a higher form of life take part in the whole path of evolution to the natural end, i.e., death. Some among them, the reproductive cells, probably retain the original structure of the living substance and, after a given time, detach themselves from the parent organism, charged as they are with all the inherited and newly acquired instinctive dispositions. Possibly it is just those two features that make their independent existence possible. If brought under favourable conditions they begin to develop, that is, to repeat the same cycle to which they owe their origin, the end being that again one portion of the substance carries

through its development to a finish, while another part, as a new germinal core, again harks back to the beginning of the development. Thus, these reproductive cells operate against the death of the living substance and are able to win for it what must seem to us to be potential immortality, although perhaps it only means a lengthening of the path to death. Of the highest significance is the fact that the reproductive cell is fortified for this function, or only becomes capable of it, by the mingling with another like it and yet different from it.

There is a group of instincts that care for the destinies of these elementary organisms which survive the individual being, that concern themselves with the safe sheltering of these organisms as long as they are defenceless against the stimuli of the outer world, and finally bring about their conjunction with other reproductive cells. These are collectively the sexual instincts. They are conservative in the same sense as the others are, in that they reproduce earlier conditions of the living substance; but they are so in a higher degree, in that they show themselves specially resistant to external influences; and they are more conservative in a wider sense still, since they preserve life itself for a longer time. They are the actual life-instincts; the fact that they run counter to the trend of the other instincts which lead towards death indicates a contradiction between them and the rest, one which the theory of neuroses has recognized as full of significance. There is, as it were, an oscillating rhythm in the life of organisms; the one group of instincts presses forward to reach the final goal of life as quickly as possible, the other flies back at a certain point on the way only to traverse the same stretch once more from a given spot and thus to prolong the duration of the journey. Although sexuality and the distinction of the sexes certainly did not exist at the dawn of life, nevertheless, it remains possible that the instincts which are later described as sexual were active from the very beginning and took up the part of opposition to the rôle of the *ego-instincts* then, and not only at some later time.

Let us now retrace our steps for the first time, to ask whether all these speculations are not, after all, without foundation. Are there really, *apart from the sexual instincts*, no other instincts than those which have as their object the reinstatement of an earlier condition, none that strive towards a condition never yet attained? I am not aware of any satisfactory example in the organic world running counter to

the characteristic I have suggested. The existence of a general impulse towards higher development in the plant and animal world can certainly not be established, though some such line of development is as a fact unquestionable. But, on the one hand, it is often merely a question of our own valuation when we pronounce one stage of development to be higher than another, and, on the other hand, biology makes clear to us that a higher development in one particular is often purchased with, or balanced by, retrogression in another. Then there are plenty of animal forms the youthful stages of which teach us that their development has taken a retrograde character rather than otherwise. Higher development and retrogression alike might well be the results of external forces impelling towards adaptation, and the part played by the instincts might be confined in both cases to retaining the enforced changes as sources of pleasure.<sup>1</sup>

Many of us will also find it hard to abandon our belief that in man himself there dwells an impulse towards perfection, which has brought him to his present heights of intellectual prowess and ethical sublimation, and from which it might be expected that his development into superman will be ensured. But I do not believe in the existence of such an inner impulse, and I see no way of preserving this pleasing illusion. The development of man up to now does not seem to me to need any explanation differing from that of animal development, and the restless striving towards further perfection which may be observed in a minority of human beings is easily explicable as the result of that repression of instinct upon which what is most valuable in human culture is built. The repressed instinct never ceases to strive after its complete satisfaction, which would consist in the repetition of a primary experience of satisfaction: all substitution- or reaction-formations and sublimations avail nothing towards relaxing the continual tension; and out of the excess of the satisfaction demanded over that found is born the driving momentum which allows of no abiding in any situation presented to it, but in the poet's words "urges ever for-

ward, ever unsubdued."<sup>2</sup> The path in the other direction, back to complete satisfaction, is as a rule barred by the resistances that maintain the repressions, and thus there remains nothing for it but to proceed in the other, still unobstructed direction, that of development, without, however, any prospect of being able to bring the process to a conclusion or to attain the goal. What occurs in the development of a neurotic phobia, which is really nothing but an attempt at flight from the satisfaction of an instinct, gives us the prototype for the origin of this ostensible "impulse towards perfection," which, however, we cannot possibly ascribe to all human beings. The dynamic conditions are, it is true, quite generally present, but the economic relations seem only in rare cases to favour the phenomenon.

## VI

OUR discussion so far results in the establishing of a sharp antithesis between the *ego-instincts* and the sexual instincts, the former impelling towards death and the latter towards the preservation of life, a result which we ourselves must surely find in many respects far from adequate. Further, only for the former can we properly claim the conservative—or, better, regressive—character corresponding to a repetition-compulsion. For, according to our hypothesis, the ego-instincts spring from the vitalizing of inanimate matter, and have as their aim the reinstatement of lifelessness. As to the sexual instincts, on the other hand: it is obvious that they reproduce primitive states of the living being, but the aim they strive for by every means is the union of two germ cells which are specifically differentiated. If this union does not take place, then the germ cell dies like all other elements of the multicellular organism. Only on this condition can the sexual function prolong life and lend it the semblance of immortality. Of what important happening, then, in the process of development of the living substance is sexual reproduction, or its forerunner, the copulation of two individual protozoa, the repetition? That question we do not know how to answer, and therefore we should feel relieved if the whole structure of our arguments were to prove erroneous. The opposition of ego- (or death-) instincts and sexual (life-) instincts would then disappear, and the repetition-compulsion would thereupon

<sup>1</sup> By a different route, Ferenczi has arrived at the possibility of this conception. ("Stages of Development in the Sense of Reality," Ch. VIII of his *Contributions to Psycho-Analysis*, 1916.) He writes: "By following through this process of thought logically, one is obliged to gain familiarity with the idea of a tendency to persistence or regression governing organic life also, while the tendency to progress in development, adaptation, etc., is manifested only as against external stimuli."

<sup>2</sup> Mephistopheles in *Faust*; Part I, "Faust's Study."

also lose the significance we have attributed to it.

Let us turn back, therefore, to one of the assumptions we interpolated, in the expectation that it will permit of exact refutation. We built up further conclusions on the basis of the assumption that all life must die from internal causes. We made this assumption so light-heartedly because it does not seem to us to be one. We are accustomed so to think, and every poet encourages us in the idea. Perhaps we have resolved so to think because there lies a certain consolation in this belief. If man must himself die, after first losing his most beloved ones by death, he would prefer that his life be forfeit to an inexorable law of nature, the sublime *Ἀνάγκη*, than to a mere accident which perhaps could have been in some way avoided. But perhaps this belief in the incidence of death as the necessary consequence of an inner law of being is also only one of those illusions that we have fashioned for ourselves "so as to endure the burden of existence." It is certainly not a primordial belief: the idea of a *natural death* is alien to primitive races; they ascribe every death occurring among themselves to the influence of an enemy or an evil spirit. So let us not neglect to turn to biological science to test the belief.

If we do so, we may be astonished to find how little agreement exists among biologists on the question of natural death, that indeed the very conception of death altogether eludes them. The fact of a certain average length of life, at least among the higher animals, is of course an argument for death from inner causes, but the circumstance that certain large animals and giant trees reach a very great age, one not to be computed up to now, once more removes this impression. According to the grandiose conception of W. Fliess, all the vital phenomena—and certainly also death—are linked with the accomplishment of certain periods of time, among which there finds expression of the dependence of two living substances, one male and one female, upon the solar year. But observations of how easily and extensively the influences of external forces can alter vital manifestations, especially in the plant world, as to their occurrence in time, can hasten or retard them, militate against the rigidity of the formulae laid down by Fliess and leaves at least doubtful the universality of the laws he sought to establish.

The treatment of these themes, death and the duration of life among organisms, in the

works of A. Weismann<sup>1</sup> possesses the greatest interest for us. This investigator originated the distinction of living substance into a mortal and an immortal half; the mortal is the body in the narrower sense, the soma, which alone is subject to natural death; while the germ cells are potentially immortal, in so far as they are capable under certain favourable conditions of developing into a new individual, or, expressed otherwise, of surrounding themselves with a new soma.<sup>2</sup>

What here arrests our attention is the unexpected analogy with our conception developed along so different a line of thought. Weismann, who is considering living substance morphologically, recognizes in it a constituent which is the prey of death, the soma, the body viewed apart from sex or heredity elements, and, on the other hand, an immortal part, the germ-plasm, which serves the purpose of preservation of the species, of propagation. We have fixed our attention not on the living matter, but on the forces active in it, and have been led to distinguish two kinds of instincts: those the purpose of which is to guide life towards death, and the others, the sexual instincts, which perpetually strive for, and bring about, the renewal of life. This sounds like a dynamic corollary to Weismann's morphological theory.

This appearance of an important correspondence vanishes as soon as we examine Weismann's pronouncement on the problem of death. For Weismann admits the differentiation between the mortal soma and the immortal germ-plasm only in relation to multicellular organisms; with the unicellular beings, the individual and the reproductive cell are still one and the same.<sup>3</sup> The unicellular he thus affirms to be potentially immortal; death appears only among the metazoa, the multicellular. This death of the higher organisms is, it is true, a natural one, a death from inner causes, but it does not depend on an inherent quality of the living substance,<sup>4</sup> is not to be conceived as an absolute necessity based on the nature of life.<sup>5</sup> Death is rather a purposive contrivance, a phenomenon of adaptation to the external conditions of life, because after the differentiation of the corporeal cells into soma and germ-plasm the indefinite prolongation of the life of the

<sup>1</sup> *Über die Dauer des Lebens*, 1882; *Über Leben und Tod*, 2nd ed., 1892; *Das Keimplasma*, 1892, etc.

<sup>2</sup> *Über Leben und Tod*, 2nd ed., p. 20.

<sup>3</sup> *Über die Dauer des Lebens*, p. 38.

<sup>4</sup> *Über Leben und Tod*, 2nd ed., p. 67.

<sup>5</sup> *Über die Dauer des Lebens*, p. 33.

individual would have become a quite inexpedient luxury. With the appearance of this differentiation among multicellular organisms, death became possible and expedient. Since then, the soma of the higher organisms dies after a certain time from internal causes; the protozoa, however, remain immortal. Propagation, on the other hand, was not first introduced with death; it is, on the contrary, a primordial property of living matter like growth, in which it originated, and life has gone on uninterruptedly from its inception on the earth.<sup>1</sup>

It is easy to see that to concede natural death to the higher organisms does not greatly help our case. If death is a late acquisition of life, then death-instincts traceable to the beginning of life on this planet no longer come into question. Multicellular organisms may continue to die from internal causes, whether defect of differentiation or imperfections of their metabolism; it possesses no interest for the inquiry on which we are engaged. Such a conception and derivation of death certainly more nearly approaches the ordinary human view of it than the unwonted assumption of *death-instincts*.

The discussion which has centred round Weismann's assertions has, in my opinion, had no decisive result in any direction.<sup>2</sup> Many writers have reverted to the standpoint of Goethe (1883), who saw in death the direct consequence of propagation. Hartmann does not regard as the characteristic of death the appearance of a *corpse*, a piece of living substance which has *died off*, but defines it as the "definitive end of individual development." In this sense, protozoa are also subject to death; with them death invariably coincides with propagation, but it is, so to speak, disguised by the latter, for the whole substance of the parent organism may be absorbed directly into the new individuals.<sup>3</sup>

The interest of the inquiry was soon directed towards testing experimentally the asserted immortality of living substance in unicellular beings. An American, named Woodruff, instituted a culture of a ciliated infusorium, a *slipper-animalcule*, which reproduces itself by division into two individuals; each time, he isolated one of the products and put it into fresh water. He traced the propagation to the 3,029th gen-

eration, when he discontinued the experiment. The last descendant of the first slipper-animalcule was just as lively as its original ancestor, without any sign of age or degeneration: if such numbers are convincing, the immortality of protozoa seemed thus experimentally demonstrable.<sup>4</sup>

Other investigators have arrived at other results. Maupas, Calkins, etc., found, in contradiction to Woodruff, that even these infusoria, after a certain number of divisions, become weaker, decrease in size, lose a portion of their organization, and finally die, if they do not encounter certain invigorating influences. According to this, protozoa die after a phase of senile decay just like higher animals, in direct contravention of what is maintained by Weismann, who recognizes in death a late acquisition of living organisms.

Taking the net result of these researches together, we note two facts which seem to afford us a firm foothold. First: if the animalculae, at a time when they as yet show no signs of age, have the opportunity of mingling with each other, of *conjugating*—afterwards again separating—then they remain exempt from age, they have been *rejuvenated*. This conjugation is doubtless the prototype of sexual propagation of higher organisms: as yet, it has nothing to do with multiplication, it is confined to the mingling of the substances of both individuals (Weismann's *Amphimixis*). The invigorating influence of conjugation can also be replaced, however, by certain modes of stimulation, changes in the composition of the nutrient fluid, raising of temperature, or shaking. The famous experiment of J. Loeb will be recalled, who, by the application of certain chemical stimuli to the ova of sea-urchins, brought about processes of division which usually take place only after fertilization.

Secondly: it is, after all, probable that the infusoria are brought to a natural death through their own vital process, for the contradiction between Woodruff's findings and those of others arises from Woodruff having placed each generation in fresh nutrient fluid. When he refrained from doing so, he observed, as did the other investigators, that the generations showed signs of age. He concluded that the animalculae were injured by the products of metabolism which they gave off into the surrounding fluid, and was then able to prove convincingly that only the products of *its own* metabolism

<sup>1</sup> *Über Leben und Tod*, Conclusion.

<sup>2</sup> See Max Hartmann, *Tod und Fortpflanzung*, 1906; Alex. Lipschütz, "Warum wir sterben," *Kosmosbücher*, 1914; Franz Doflein, *Das Problem des Todes und der Unsterblichkeit bei den Pflanzen und Tieren*, 1919.

<sup>3</sup> *Hartmann, op. cit.*, p. 29.

<sup>4</sup> For this, and what follows, see Lipschütz, *op. cit.*, pp. 26 and 52 ff.

had this effect in bringing about the death of the generation. For in a solution over-saturated with waste products of a distantly related species, the very same animalculæ thrive excellently which when allowed to accumulate in their own nutrient fluid inevitably perished. Thus, left to itself, the infusorium dies a natural death from the imperfect disposal of its own metabolic products: perhaps all higher animals die ultimately from the same inability.

At this point, the doubt may then occur to us whether any good purpose has been served in looking for the answer to the question as to natural death in the study of the protozoa. The primitive organization of these forms of life may conceal from us important conditions which are present in them too, but can be recognized only among the higher animals where they have achieved for themselves a morphological expression. If we abandon the morphological point of view for the dynamic, it may be a matter of entire indifference to us whether the natural death of the protozoa can be proved or not. With them the substance later recognized as immortal has not yet separated itself in any way from the part subject to death. The instinctive forces which endeavour to conduct life to death might be active in them, too, from the beginning and yet their effect might be so obscured by that of the forces tending to preserve life that any direct evidence of their existence becomes hard to establish. We have heard, it is true, that the observations of biologists allow us to assume such death-ward tending inner processes also among the protozoa. But even if the protozoa prove to be immortal in Weismann's sense, his assertion that death is a late acquisition holds good only of the outward manifestations of death, and does not invalidate any hypothesis as to such processes as impel towards death. Our expectation that biology would entirely put out of court any recognition of the death-instincts has not been fulfilled. It is open to us to occupy ourselves further with this possibility, if we have other reasons for doing so. The striking resemblance between Weismann's separation of soma and germ-plasm and our distinction between the death and the life-instincts remains unshaken, moreover, and retains its value.

Let us dwell for a moment on this exquisitely dualistic conception of the instinctive life. According to E. Hering's theory of the processes in living matter, there course through it uninterruptedly two kinds of processes of opposite direction, one anabolic, assimilatory, the

other katabolic, disintegrating. Shall we venture to recognize in these two directions of the vital processes the activity of our two instinctive tendencies, the life-instincts and the death-instincts? And we cannot disguise another fact from ourselves, that we have steered unawares into the haven of Schopenhauer's philosophy for whom death is the "real result" of life,<sup>1</sup> and, therefore, in so far its aim, while the sexual instinct is the incarnation of the will to live.

Let us boldly try to go a step further. According to general opinion, the union of numerous cells into one vital connection, the multicellularity of organisms, has become a means to the prolongation of their span of life. One cell helps to preserve the life of the others, and the cell-community can go on living even if single cells have to perish. We have already heard that also conjugation, the temporary mingling of two unicellular entities, has a preservative and rejuvenating effect on both. The attempt might consequently be made to transfer the libido theory yielded by psycho-analysis to the relationship of the cells to one another and to imagine that it is the vital or sexual instincts active in every cell that take the other cells for their *object*, partially neutralize their death-instincts, i.e., the processes stimulated by these, and so preserve those cells in life, while other cells do the same for them, and still others sacrifice themselves in the exercise of this libidinous function. The germ cells themselves would behave in a completely *narcissistic* fashion, as we are accustomed to describe it in the theory of the neuroses when an individual concentrates his libido on the ego, and gives out none of it for the charging of objects. The germ cells need their libido—the activity of their vital instincts—for themselves as a provision for their later enormous constructive activity. Perhaps the cells of the malignant growths that destroy the organism can also be considered to be narcissistic in the same sense. Pathology is indeed prepared to regard the kernels of them as congenital in origin and to ascribe embryonal attributes to them. Thus the libido of our sexual instincts would coincide with the Eros of poets and philosophers, which holds together all things living.

At this point, opportunity offers of reviewing the gradual development of our libido theory. The analysis of the transference-neuroses

<sup>1</sup> *Über die anscheinende Absichtlichkeit im Schicksale des Einzelnen* (edited by Grand Duke Wilhelm Ernst) Vol. IV. p. 268.

forced on our notice in the first place the opposition between *sexual instincts*, which are directed towards an object, and other instincts which we only imperfectly discerned and provisionally described as *ego-instincts*. Among the latter, those which subserve the self-preservation of the individual had the first claim for recognition. What other distinctions were to be made, it was impossible to say. No knowledge would have been so important for the establishment of a sound psychology as some approximate understanding of the common nature and possible differences of the instincts. But in no department of psychology did one grope more in the dark. Everyone posited as many instincts or *fundamental instincts* as he pleased, and contrived with them just as the ancient Greek philosophers did with their four elements: earth, air, fire, and water. Psycho-analysis, which could not dispense with some kind of hypothesis as to the instincts, adhered, to begin with, to the popular distinction, typically represented by the phrase *hunger and love*. It was at least no new arbitrary creation. With this, one adequately covered a considerable distance in the analysis of the psycho-neuroses. The conception of *sexuality*—and therewith that of a sexual instinct—certainly had to be extended, till it included much that did not come into the category of the function of propagation, and this led to outcry enough in a severe and superior or merely hypocritical world.

The next step followed when psycho-analysis was able to feel its way a little nearer to the psychological ego, which was at first known to us only as a repressing, censoring agency, capable of constituting defences and reaction-formations. Critical and other far-seeing minds had indeed for a long time raised objections to the narrowing of the libido concept down to the energy of the sexual instinct as directed to the object. But they omitted to say whence they obtained this fuller comprehension, and failed to deduce anything from it of value for psycho-analysis. In the course of more deliberate advance, it came under psycho-analytic observation how regularly libido is withdrawn from the object and directed towards the ego (introversion), and through the study of the libido development of the child in its earliest phases it became clear that the ego is the true and original reservoir of the libido, which is extended to the object only from this. The ego took its place as one of the sexual objects and was immediately recognized as the choicest

among them. Where the libido thus remained attached to the ego, it was termed *narcissistic*.<sup>1</sup> This narcissistic libido was naturally also the expression of the energy of sexual instincts in the analytical sense which now had to be identified with the *instincts of self-preservation*, the existence of which was admitted from the first. Whereupon, the original antithesis between the ego-instincts and the sexual instincts became inadequate. A part of the ego-instincts was recognized as libidinous: in the ego, sexual instincts were found to be active—probably in addition to others; nevertheless, one is justified in saying that the old formula, viz., that a psychoneurosis arises out of a conflict between the ego-instincts and the sexual instincts, contained nothing that we should have to reject today. Only, the difference of the two kinds of instincts which was supposed originally to be in some kind of way qualitative has now to be defined otherwise, namely on a topographical basis. In particular, the transference-neurosis, the real object of psycho-analytic study, is still seen to be the result of a conflict between the ego and libidinous investment of an object.

We are the more compelled now to accentuate the libidinous character of the self-preserved instincts, since we are venturing on the further step of recognizing the sexual instinct as the Eros; the all-sustaining, and of deriving the narcissistic libido of the ego from the sum of the libido quantities that bring about the mutual adherence of the somatic cells. But we now find ourselves suddenly confronted with this question: If the self-preserved instincts are also of a libidinous kind, then perhaps we have no other instincts at all than libidinous ones. There are at least no others apparent. In that event, we must admit the critics to be in the right who from the first have suspected that psycho-analysis makes sexuality the explanation of everything, or the innovators, like Jung, who, quickly making up their minds, have used *libido* as a synonym for *instinctive force* in general. Is that not so?

This result was at all events one not intended by us. On the contrary, we took as our starting point a sharp distinction between the ego-instincts (=death-instincts) and the sexual instincts (=life-instincts). We were prepared, indeed, to reckon even the alleged self-preserved instincts of the ego among death-instincts, a position which we have since corrected and withdrawn from. Our standpoint was a dualistic one from the beginning, and is so today more

<sup>1</sup> See *On Narcissism: an Introduction*, p. 399 above.

sharply than before, since we no longer call the contrasting tendencies *egoistic* and *sexual* instincts, but *life-instincts* and *death-instincts*. Jung's libido theory, on the other hand, is a monistic one; that he has applied the term *libido* to his only instinctive energy was bound to create confusion, but should not have any further effect on us. We suspect that there are in the ego other instincts than those of self-preservation; only we ought to be in a position to demonstrate them. Unfortunately, so little progress has been made in the analysis of the ego that this proof becomes extraordinarily difficult of attainment. The libidinous instincts of the ego may indeed be conjoined in a special way with other ego-instincts of which we as yet know nothing. Before ever we had clearly recognized narcissism, the conjecture was already present in the minds of psycho-analysts that the *ego-instincts* had drawn libidinous components to themselves. But these are merely vague possibilities which our opponents will hardly take into account. It remains an awkward fact that analysis up to now has only put us in the position of demonstrating libidinous impulses. The conclusion that therefore there are no others is one to which we do not assent.

In the obscurity that at present shrouds the theory of instinct, we shall certainly not do well to reject any idea that promises to throw light. We have made the antithesis between the life and death instincts our point of departure. Object-love itself displays a second such polarity, that of love (tenderness) and hate (aggression). What if we could succeed in bringing these two polarities into relation with each other, in tracing the one to the other! We have long recognized a sadistic component of the sexual instinct;<sup>1</sup> it can, as we know, attain independence, and as a perversion, dominate the whole sexual trend of a person. In one of the organizations which I have termed *pregenital* it appears as a dominating part-instinct. But how is one to derive the sadistic impulse, which aims at the injury of the object, from the life-sustaining Eros! Does not the assumption suggest itself that this sadism is properly a death-instinct which is driven apart from the ego by the influence of the narcissistic libido, so that it becomes manifest only in reference to the object? It then enters the service of the sexual function; at the oral stage of organization of the libido, amorous possession is still one and the same as annihilation of the object;

later, the sadistic impulse separates itself, and, at last, at the stage of the genital primacy, it takes over, with the aim of propagation, the function of so far overpowering the sex-object as the carrying out of the sexual act demands. One might even say that the sadism expelled from the ego has acted as guide to the libidinous components of the sexual instinct; these later press on towards the object. Where the original sadism experiences no abatement or fusion, the well-known hate-love ambivalence of the love-life is set up.

If the above assumption is justifiable, then we have met the challenge of demonstrating an example of a death-instinct—though a displaced one. This conception, however, is far from being evident, and creates a frankly mystical impression. We incur the suspicion of having attempted at all costs to find a way out of an *impasse*. We may appeal against this verdict by saying that the assumption is no new one, that we have once before made it when there was no question of an *impasse*. Clinical observations forced upon us the view that the part-instinct of masochism, the one complementary to sadism, is to be understood as a recoil of the sadism on to the ego itself.<sup>2</sup> A turning of the instinct from the object to the ego is, however, essentially the same as a turning from the ego to the object, which is just now the new idea in question. Masochism, the turning of the instinct against the self, would then be in reality a return to an earlier phase of this, a regression. The exposition I then gave of masochism needs correction in one respect as being too exclusive: masochism may also be what I was there concerned to deny, primary.<sup>3</sup>

Let us return, however, to the life-sustaining sexual instincts. We have already learned from the investigation of the protozoa that the mingling of two individuals without consequent

<sup>2</sup> See *Three Contributions to the Theory of Sex and Instincts and their Vicissitudes*, p. 412 above.

<sup>3</sup> A considerable part of this speculation has been anticipated in a work which is full of valuable matter and ideas but is unfortunately not entirely clear to me: Sabina Spielrein, "*Die Destruktion als Ursache des Werdens*," *Jahrbuch für Psychoanalyse*, IV, 1912. She designates the sadistic component as *destructive*. In still another way, A. Stärcke (*Imleiding by de vertaling von S. Freud, De sexuele beschavingsmoral*, etc., 1914), has attempted to identify the libido concept itself with the biological concept of an impulsion towards death which is to be assumed on theoretical grounds. (See also Rank, *Der Künstler*.) All these attempts, as the one in the text, indicate how much the need is felt for a clarification, in the theory of instinct, which we do not yet possess.

<sup>1</sup> *Three Contributions to the Theory of Sex*.

partition, just as copulation between two individuals which soon after separate, has a strengthening and rejuvenating effect (see above, Lipschütz). There is no sign of degeneration in their descendants, and they also seem to have gained the capacity for withstanding for a longer time the injurious results of their own metabolism. I think that this one observation may be taken as a prototype of the effect of sexual intercourse also. But in what way does the blending of two slightly different cells bring about such a renewal of life? The experiment which substitutes for conjugation among protozoa the effect of chemical or even of mechanical stimuli<sup>1</sup> admits of our giving a reply with certainty: it comes about by the introduction of new stimulus-masses. This is in close agreement with the hypothesis that the life-process of an individual leads, from internal causes, to the equalizing of chemical tensions: i.e., to death, while union with an individually different living substance increases these tensions—so to speak, introduces new vital differentia, which then have to be again lived out. For this difference between the two there must naturally be one or more optima. Our recognition that the ruling tendency of psychic life, perhaps of nerve life altogether, is the struggle for reduction, keeping at a constant level, or removal of the inner stimulus tension (the Nirvana-principle, as Barbara Low terms it)—a struggle which comes to expression in the pleasure-principle—is indeed one of our strongest motives for believing in the existence of death-instincts.

But the course of our argument is still disturbed by an uneasy feeling that just in the case of the sexual instinct we are unable to demonstrate that character of a repetition-compulsion which first put us on the track of the death-instincts. It is true that the realm of embryonic developmental processes offers an abundance of such repetition phenomena—the two germ cells of sexual propagation and their life-history are themselves only repetitions of the beginning of organic life: but the essential feature in the processes designed by the sexual instinct is, nevertheless, the mingling of two cells. Only by this is the immortality of the living substance among the higher forms of life assured.

To put it in other words: we have to make enquiry into the origin of sexual propagation and the source of the sexual instincts in general, a task before which the lay mind quails and

which even specialists have not yet been able to solve. Let us, therefore, make a condensed selection from all the conflicting accounts and opinions of whatever can be brought into relation with our train of thought.

One view deprives the problem of propagation of its mysterious attraction by representing it as part of the phenomenon of growth (multiplication by division, germination, budding). The arising of propagation by means of germ-cells sexually differentiated might be conceived, in accordance with the sober Darwinian mode of thought, as a way of maintaining and utilizing for further development the advantage of the amphimixis which resulted in the first instance from the fortuitous conjugation of two protozoa.<sup>2</sup> Sex would not thus be of very ancient origin and the extraordinarily powerful instincts which aim at bringing about sexual union would thereby repeat something which once chanced to happen and since became established as being advantageous.

The same question now recurs as arose in respect of death—namely, whether the protozoa can be credited with anything beyond what they exhibit, and whether we may assume that forces and processes which become perceptible only in the case of the higher animals did first arise in the more primitive. For our purpose the view of sexuality mentioned above helps very little. The objection may be raised against it that it presupposes the existence of life-instincts as already operative in the simplest forms of life, for otherwise conjugation, which works against the expiration of life and makes the task of dying harder, would not have been retained and elaborated, but would have been avoided. If, then, we are not to abandon the hypothesis of death-instincts maintained, we must associate them with life-instincts from the beginning. But we must admit that we are working here at an equation with two unknown quantities. Anything else that science can tell us of the origin of sexuality amounts to so little that this problem may be likened to an obscurity into which not even the ray of an hypothesis has penetrated. In quite another quarter, however, we encounter such an hypothesis, but it is of so fantastic a kind—assuredly a myth rather than a scientific explanation—

<sup>2</sup> Although Weismann (*Das Keimplasma*, 1892) denies even this advantage: "Fertilization in no way signifies a rejuvenation or renewing of life—it is in no way necessary for the prolongation of life; it is nothing but a device for making possible the blending of two different inheritance tendencies." Still, he considers an increase of variability in living organisms to be the result of such blending.

<sup>1</sup> *Loc. cit.*

that I should not venture to bring it forward if it did not exactly fulfil the one condition for the fulfilment of which we are labouring. That is to say, it derives an instinct from the necessity for the reinstatement of an earlier situation.

I refer, of course, to the theory that Plato in his *Symposium* puts into the mouth of Aristophanes and which deals not only with the origin of the sexual instinct but also with its most important variations in relation to the object. "Human nature was once quite other than now. Originally there were three sexes, three and not as today two: besides the male and the female there existed a third sex which had an equal share in the two first. . . . In these beings everything was double: thus, they had four hands and four feet, two faces, two genital parts, and so on. Then Zeus allowed himself to be persuaded to cut these beings in two, as one divides pears to stew them. . . . When all nature was divided in this way, to each human being came the longing for his own other half, and the two halves embraced and entwined their bodies and desired to grow together again."<sup>1</sup>

Are we to follow the clue of the poet-philosopher and make the daring assumption that living substance was at the time of its animation

<sup>1</sup> I am indebted to Prof. Heinrich Gomperz of Vienna for the following indications as to the origin of the Platonic myth, which I repeat partly in his own words: I should like to call attention to the fact that essentially the same theory is also to be found in the Upanishads. The Brihad-Aranyaka Upanishad I, 4, 3 (Deussen, 60 Upanishads des Veda, p. 393), where the creation of the world from the *Ātman* (the self or ego) is described, has the following passage: "Nor did he [the *Ātman*, the self or ego] experience any joy, and for that reason no one has joy when he is alone. So he longed for a partner. He was as big as a woman and a man together when they embrace. He divided himself into two parts, which made a husband and a wife. This body is, therefore, one half of the self, according to *Yajnavalkya*. And for the same reason this empty space here becomes filled by the woman."

The Brihad-Aranyaka Upanishad is the oldest of all the Upanishads, and no expert authority would date it later than 800 B.C. In opposition to the prevailing opinion, I should not like definitely to deny the possibility of Plato having been dependent, even though very indirectly, on these Indian thoughts, for this possibility cannot be absolutely put aside even for the doctrine of re-incarnation. A dependence of this sort, first conveyed through Pythagoras, would scarcely detract from the significance of the coincidence in thought, for Plato would not have adopted any such story conveyed in some way from Oriental traditions, let alone have given it such an important place, had he not himself felt the truth contained in it to be illuminating.

In an article by K. Ziegler ("*Menschen- und Weltwerden*," *Neue Jahrbücher für das klassische Altertum*, Vol. XXXI, 1913), which contains a systematic investigation of the thought in question, it is traced back to Babylonian ideas.

rent into small particles, which since that time strive for reunion by means of the sexual instincts? That these instincts—in which the chemical affinity of inanimate matter is continued—passing through the realm of the protozoa gradually overcome all hindrances set to their striving by an environment charged with stimuli dangerous to life, and are impelled by it to form a protecting covering layer? And that these dispersed fragments of living substance thus achieve a multicellular organization, and finally transfer to the germ-cells in a highly concentrated form the instinct for reunion? I think this is the point at which to break off.

But not without a few words of critical reflection in conclusion. I might be asked whether I am myself convinced of the views here set forward, and if so how far. My answer would be that I am neither convinced myself, nor am I seeking to arouse conviction in others. More accurately: I do not know how far I believe in them. It seems to me that the affective feature *conviction* need not come into consideration at all here. One may surely give oneself up to a line of thought, and follow it up as far as it leads, simply out of scientific curiosity, or—if you prefer—as *advocatus diaboli*, without, however, making a pact with the devil about it. I am perfectly aware that the third step in the theory of instinct which I am taking here cannot claim the same certainty as the two former ones, viz., the extending of the conception of sexuality and the establishing of narcissism. These innovations were direct translations of observation into theory, subject to no greater sources of error than is inevitable in anything of the kind. The assertion of the regressive character of instinct rests also, it is true, on observed material, namely, on the facts of the repetition-compulsion. But perhaps I have overestimated their significance. At all events there is no way of working out this idea except by combining facts with pure imagination many times in succession, and thereby departing far from observation. We know that the final result becomes the more untrustworthy the oftener one does this in the course of building up a theory, but the precise degree of uncertainty is not ascertainable. One may thereby have made a brilliant discovery or one may have gone ignominiously astray. In such work I trust little to so-called *intuition*: what I have seen of it seems to me to be the result of a certain impartiality of the intellect—only that people, unfortunately, are seldom impartial

where they are concerned with the ultimate things, the great problems of science and of life. My belief is that there everyone is under the sway of preferences deeply rooted within, into the hands of which he unwittingly plays as he pursues his speculation. Where there are such good grounds for distrust, only a tepid feeling of indulgence is possible towards the results of one's own mental labours. But I hasten to add that such self-criticism does not render obligatory any special tolerance of divergent opinions. One may inexorably reject theories that are contradicted by the very first steps in the analysis of observation and yet at the same time be aware that those one holds oneself have only a tentative validity. Were we to appraise our speculations upon the life- and death instincts it would disturb us but little that so many processes go on which are surprising and hard to picture, such as one instinct being expelled by others, or turning from the ego to an object, and so on. This comes only from our being obliged to operate with scientific terms, i.e., with the metaphorical expressions peculiar to psychology (or more correctly: psychology of the deeper layers). Otherwise, we should not be able to describe the corresponding processes at all, nor, in fact, even to have remarked them. The shortcomings of our description would probably disappear if for the psychological terms we could substitute physiological or chemical ones. These, too, only constitute a metaphorical language, but one familiar to us for a much longer time and perhaps also simpler.

On the other hand, we wish to make it quite clear that the uncertainty of our speculation is enhanced in a high degree by the necessity of borrowing from biological science. Biology is truly a realm of limitless possibilities; we have the most surprising revelations to expect from it, and cannot conjecture what answers it will offer in some decades to the questions we have put to it. Perhaps, they may be such as to overthrow the whole artificial structure of hypotheses. If that is so, someone may ask why does one undertake such work as the one set out in this article, and why should it be communicated to the world? Well, I cannot deny that some of the analogies, relations and connections therein traced appeared to me worthy of consideration.<sup>1</sup>

<sup>1</sup> I would here subjoin a few words to clarify our nomenclature, one which has undergone a certain development in the course of our discussion. What *sexual instincts* are, we knew through their relation to the sexes and to the function of propagation. We then retained this term when the findings of psycho-

If this attempt to reinstate an earlier condition really is so universal a characteristic of the instincts, we should not find it surprising that so many processes in the psychic life are performed independently of the pleasure-principle. This characteristic would communicate itself to every part-instinct and would in that case concern a harking back to a definite point on the path of development. But all that the pleasure-principle has not yet acquired power over is not therefore necessarily in opposition to it, and we have not yet solved the problem of determining the relation of the instinctive repetition processes to the domination of the pleasure-principle.

We have recognized that one of the earliest and most important functions of the psychic apparatus is to *bind* the instreaming instinctive excitations, to substitute the *secondary process* for the *primary process* dominating them, and to transform their freely mobile energy-charge into a predominantly quiescent (tonic) charge. During this transformation, no attention can be paid to the development of the "pain," but the pleasure-principle is not thereby annulled. On the contrary, the transformation takes place in the service of the pleasure-principle; the binding is an act of preparation, which introduces and secures its sovereignty.

analysis compelled us to regard its relation to propagation as less close. With the discovery of narcissistic libido, and the extension of the libido-concept to the individual cells, the sexual instinct became for us transformed into the Eros that endeavours to impel the separate parts of living matter to one another and to hold them together; what is commonly called the *sexual instinct* appears as that part of the Eros that is turned towards the object. Our speculation then supposes that this Eros is at work from the beginnings of life, manifesting itself as the *life-instinct* in contradistinction to the *death-instinct* which developed through the animation of the inorganic. It endeavours to solve the riddle of life by the hypothesis of these two instincts striving with each other from the very beginning. The transformation which the concept of the *ego-instincts* has undergone is perhaps harder to review. Originally, we applied this term to all those instinct-directions—now better known to us—which can be distinguished from the sexual instincts that have the object as their aim, thus contrasting the ego-instincts with the sexual ones, the expression of which is the libido. Later on, we approached the analysis of the ego and saw that a part also of the ego-instincts is of a libidinous nature, having taken its own self as an object. These narcissistic instincts of self-preservation, therefore, had now to be reckoned to the libidinous sexual instincts. The contrast between egoistic and sexual instincts was now converted into one between egoistic and object-instincts, both libidinous in nature. In its place, however, arose a new contrast between libidinous (ego and object) instincts and others whose existence can be determined in the ego and can perhaps be detected in the destruction-instincts. Speculation transforms this contrast into that of life-instincts (Eros) and death-instincts.

Let us distinguish function and tendency more sharply than we have hitherto done. The pleasure-principle is, then, a tendency which subserves a certain function—namely, that of rendering the psychic apparatus as a whole free from any excitation, or to keep the amount of excitation constant or as low as possible. We cannot yet decide with certainty for either of these conceptions, but we note that the function so defined would partake of the most universal tendency of all living matter—to return to the peace of the inorganic world. We all know by experience that the greatest pleasure it is possible for us to attain, that of the sexual act, is bound up with the temporary quenching of a greatly heightened state of excitation. The *binding* of instinct-excitation, however, would be a preparatory function, which would direct the excitation towards its ultimate adjustment in the pleasure of discharge.

In the same connection, the question arises whether the sensations of pleasure and "pain" can emanate as well from the bound as from the *unbound* excitation-processes. It appears quite beyond doubt that the *unbound*, the primary, processes give rise to much more intense sensations in both directions than the bound ones, those of the *secondary processes*. The primary processes are also the earlier in point of time; at the beginning of mental life there are no others, and we may conclude that if the pleasure-principle were not already in action in respect to them, it would not establish itself in regard to the later processes. We thus arrive at the result which at bottom is not a simple one, that the search for pleasure manifests itself with far greater intensity at the beginning of psychic life than later on, but less unrestrictedly: it has to put up with repeated breaches. At a maturer age the dominance of the pleasure-principle is very much more assured, though this principle as little escapes limitations as all the other instincts. In any case, whatever it is in the process of excitation that engenders the sensations of pleasure and "pain" must be equally in existence when the secondary process

is at work as with the primary process.

This would seem to be the place to institute further studies. Our consciousness conveys to us from within not only the sensations of pleasure and "pain," but also those of a peculiar tension, which again may be either pleasurable or painful in itself. Now, is it the *bound* and *unbound* energy processes that we have to distinguish from each other by the help of these sensations, or is the sensation of tension to be related to the absolute quantity, perhaps to the level of the charge, while the pleasure-pain series refers to the changes in the quantity of charge in the unit of time? We must also be struck with the fact that the life-instincts have much more to do with our inner perception, since they make their appearance as disturbers of the peace, and continually bring along with them states of tension the resolution of which is experienced as pleasure; while the death-instincts, on the other hand, seem to fulfil their function unostentatiously. The pleasure-principle seems directly to subserve the death-instincts; it keeps guard, of course, also over the external stimuli, which are regarded as dangers by both kinds of instincts, but in particular over the inner increases in stimulation which have for their aim the complication of the task of living. At this point, innumerable other questions arise to which no answer can yet be given. We must be patient and wait for other means and opportunities for investigation. We must hold ourselves, too, in readiness to abandon the path we have followed for a time, if it should seem to lead to no good result. Only such "true believers" as expect from science a substitute for the creed they have relinquished will take it amiss if the investigator develops his views further or even transforms them.

For the rest we may find consolation in the words of a poet for the slow rate of progress in scientific knowledge:

*Whither we cannot fly, we must go limping.  
The Scripture saith that limping is no sin.<sup>1</sup>*

<sup>1</sup> Rückert in the *Makamen des Hariri*.

# Group Psychology and the Analysis of the Ego

## I. INTRODUCTION

THE contrast between individual psychology and social or group<sup>1</sup> psychology, which at a first glance may seem to be full of significance, loses a great deal of its sharpness when it is examined more closely. It is true that individual psychology is concerned with the individual man and explores the paths by which he seeks to find satisfaction for his instincts; but only rarely and under certain exceptional conditions is individual psychology in a position to disregard the relations of this individual to others. In the individual's mental life someone else is invariably involved, as a model, as an object, as a helper, as an opponent, and so from the very first individual psychology is at the same time social psychology as well—in this extended but entirely justifiable sense of the words.

The relations of an individual to his parents and to his brothers and sisters, to the object of his love, and to his physician—in fact all the relations which have hitherto been the chief subject of psycho-analytic research—may claim to be considered as social phenomena; and in this respect they may be contrasted with certain other processes, described by us as *narcissistic*, in which the satisfaction of the instincts is partially or totally withdrawn from the influence of other people. The contrast between social and narcissistic—Bleuler would perhaps call them *autistic*—mental acts therefore falls wholly within the domain of individual psychology, and is not well calculated to differentiate it from a social or group psychology.

The individual in the relations which have already been mentioned—to his parents and to his brothers and sisters, to the person he is in love with, to his friend, and to his physician—comes under the influence of only a single person, or of a very small number of persons, each

one of whom has become enormously important to him. Now in speaking of social or group psychology it has become usual to leave these relations on one side and to isolate as the subject of inquiry the influencing of an individual by a large number of people simultaneously, people with whom he is connected by something, though otherwise they may in many respects be strangers to him. Group psychology is therefore concerned with the individual man as a member of a race, of a nation, of a caste, of a profession, of an institution, or as a component part of a crowd of people who have been organized into a group at some particular time for some definite purpose. When once natural continuity has been severed in this way, it is easy to regard the phenomena that appear under these special conditions as being expressions of a special instinct that is not further reducible, the social instinct (herd instinct, group mind), which does not come to light in any other situations. But we may perhaps venture to object that it seems difficult to attribute to the factor of number a significance so great as to make it capable by itself of arousing in our mental life a new instinct that is otherwise not brought into play. Our expectation is therefore directed towards two other possibilities: that the social instinct may not be a primitive one and insusceptible of dissection, and that it may be possible to discover the beginnings of its development in a narrower circle, such as that of the family.

Although group psychology is only in its infancy, it embraces an immense number of separate issues and offers to investigators countless problems which have hitherto not even been properly distinguished from one another. The mere classification of the different forms of group formation and the description of the mental phenomena produced by them require a great expenditure of observation and exposition, and have already given rise to a copious literature. Anyone who compares the narrow dimensions of this little book with the extent of group psychology will at once be able to guess that only a few points chosen from the whole material are to be dealt with here.

<sup>1</sup> "Group" is used throughout this translation as equivalent to the rather more comprehensive German *Masse*. The author uses this latter word to render both McDougall's *group*, and also Le Bon's *foule*, which would more naturally be translated *crowd* in English. For the sake of uniformity, however, *group* has been preferred in this case as well, and has been substituted for *crowd* even in the extracts from the English translation of Le Bon.—Tr.

And they will in fact only be a few questions with which the depth-psychology of psycho-analysis is specially concerned.

## II. LE BON'S DESCRIPTION OF THE GROUP MIND

INSTEAD of starting from a definition, it seems more useful to begin with some indication of the range of the phenomena under review, and to select from among them a few specially striking and characteristic facts to which our inquiry can be attached. We can achieve both of these aims by means of quotation from Le Bon's deservedly famous work, *Psychologie des Foules*.<sup>1</sup>

Let us make the matter clear once again. If a psychology, concerned with exploring the predispositions, the instincts, the motives, and the aims of an individual man down to his actions and his relations with those who are nearest to him, had completely achieved its task, and had cleared up the whole of these matters with their inter-connections, it would then suddenly find itself confronted by a new task which would lie before it unachieved. It would be obliged to explain the surprising fact that under a certain condition this individual whom it had come to understand thought, felt, and acted in quite a different way from what would have been expected. And this condition is his insertion into a collection of people which has acquired the characteristic of a *psychological group*. What, then, is a *group*? How does it acquire the capacity for exercising such a decisive influence over the mental life of the individual? And what is the nature of the mental change which it forces upon the individual?

It is the task of a theoretical group psychology to answer these three questions. The best way of approaching them is evidently to start with the third. Observation of the changes in the individual's reactions is what provides group psychology with its material; for every attempt at an explanation must be preceded by a description of the thing that is to be explained.

I will now let Le Bon speak for himself. He says: "The most striking peculiarity presented by a psychological group<sup>2</sup> is the following. Whoever be the individuals that compose it, however like or unlike be their mode of life, their occupations, their character, or their intelligence, the fact that they have been transformed into a group puts them in possession of

a sort of collective mind which makes them feel, think, and act in a manner quite different from that in which each individual of them would feel, think, and act were he in a state of isolation. There are certain ideas and feelings which do not come into being, or do not transform themselves into acts except in the case of individuals forming a group. The psychological group is a provisional being formed of heterogeneous elements, which for a moment are combined, exactly as the cells which constitute a living body form by their reunion a new being which displays characteristics very different from those possessed by each of the cells singly" (p. 29).<sup>3</sup>

We shall take the liberty of interrupting Le Bon's exposition with glosses of our own, and shall accordingly insert an observation at this point. If the individuals in the group are combined into a unity, there must surely be something to unite them, and this bond might be precisely the thing that is characteristic of a group. But Le Bon does not answer this question; he goes on to consider the alteration which the individual undergoes when in a group and describes it in terms which harmonize well with the fundamental postulates of our own depth-psychology.

"It is easy to prove how much the individual forming part of a group differs from the isolated individual, but it is less easy to discover the causes of this difference.

"To obtain at any rate a glimpse of them, it is necessary in the first place to call to mind the truth established by modern psychology, that unconscious phenomena play an altogether preponderating part not only in organic life, but also in the operations of the intelligence. The conscious life of the mind is of small importance in comparison with its unconscious life. The most subtle analyst, the most acute observer, is scarcely successful in discovering more than a very small number of the conscious motives that determine his conduct. Our conscious acts are the outcome of an unconscious substratum created in the mind in the main by hereditary influences. This substratum consists of the innumerable common characteristics handed down from generation to generation, which constitute the genius of a race. Behind the avowed causes of our acts there undoubtedly lie secret causes that we do not avow, but behind these secret causes there are many others more secret still, of which we ourselves are ignorant. The greater part of our

<sup>1</sup> *The Crowd: a Study of the Popular Mind* (Fisher Unwin, 12th Impression, 1920).

<sup>2</sup> See footnote page 664.—TR.

<sup>3</sup> References are to the English translation.—TR.

daily actions are the result of hidden motives which escape our observation" (p. 30).

Le Bon thinks that the particular acquisitions of individuals become obliterated in a group, and that in this way their distinctiveness vanishes. The racial unconscious emerges; what is heterogeneous is submerged in what is homogeneous. We may say that the mental superstructure, the development of which in individuals shows such dissimilarities, is removed, and that the unconscious foundations, which are similar in everyone, stand exposed to view.

In this way individuals in a group would come to show an average character. But Le Bon believes that they also display new characteristics which they have not previously possessed, and he seeks the reason for this in three different factors.

"The first is that the individual forming part of a group acquires, solely from numerical considerations, a sentiment of invincible power which allows him to yield to instincts which, had he been alone, he would perforce have kept under restraint. He will be the less disposed to check himself from the consideration that, a group being anonymous, and in consequence irresponsible, the sentiment of responsibility which always controls individuals disappears entirely" (p. 33).

From our point of view we need not attribute so much importance to the appearance of new characteristics. For us it would be enough to say that in a group the individual is brought under conditions which allow him to throw off the repressions of his unconscious instincts. The apparently new characteristics which he then displays are in fact the manifestations of this unconscious, in which all that is evil in the human mind is contained as a predisposition. We can find no difficulty in understanding the disappearance of conscience or of a sense of responsibility in these circumstances. It has long been our contention that "dread of society" (*soziale Angst*) is the essence of what is called *conscience*.<sup>1</sup>

"The second cause, which is contagion, also intervenes to determine the manifestation in

groups of their special characteristics, and at the same time the trend they are to take. Contagion is a phenomenon of which it is easy to establish the presence, but that it is not easy to explain. It must be classed among those phenomena of a hypnotic order, which we shall shortly study. In a group every sentiment and act is contagious, and contagious to such a degree that an individual readily sacrifices his personal interest to the collective interest. This is an aptitude very contrary to his nature, and of which a man is scarcely capable, except when he makes part of a group" (p. 33).

We shall later on base an important conjecture upon this last statement.

"A third cause, and by far the most important, determines in the individuals of a group special characteristics which are quite contrary at times to those presented by the isolated individual. I allude to that suggestibility of which, moreover, the contagion mentioned above is only an effect.

"To understand this phenomenon it is necessary to bear in mind certain recent physiological discoveries. We know today that by various processes an individual may be brought into such a condition that, having entirely lost his conscious personality, he obeys all the suggestions of the operator who has deprived him of it, and commits acts in utter contradiction with his character and habits. The most careful investigations seem to prove that an individual immersed for some length of time in a group in action soon finds himself—either in consequence of the magnetic influence given out by the group, or from some other cause of which we are ignorant—in a special state, which much resembles the state of fascination in which the hypnotized individual finds himself in the hands of the hypnotizer. . . . The conscious personality has entirely vanished; will and discernment are lost. All feelings and thoughts are bent in the direction determined by the hypnotizer.

"Such also is approximately the state of the individual forming part of a psychological group. He is no longer conscious of his acts. In his case, as in the case of the hypnotized subject, at the same time that certain faculties are destroyed, others may be brought to a high degree of exaltation. Under the influence of a suggestion, he will undertake the accomplishment of certain acts with irresistible impetuosity. This impetuosity is the more irresistible in the case of groups than in that of the hypnotized subject, from the fact that, the suggestion

<sup>1</sup> There is some difference between Le Bon's view and ours, owing to his concept of the unconscious not quite coinciding with the one adopted by psychoanalysis. Le Bon's unconscious more especially contains the most deeply buried features of the racial mind, which, as a matter of fact, lies outside the scope of psychoanalysis. We do not fail to recognize, indeed, that the ego's nucleus, which comprises the "archaic inheritance" of the human mind, is unconscious; but in addition to this we distinguish the *unconscious repressed*, which arose from a portion of that inheritance. This concept of the repressed is not to be found in Le Bon.

being the same for all the individuals of the group, it gains in strength by reciprocity" (p. 34).

"We see, then, that the disappearance of the conscious personality, the predominance of the unconscious personality, the turning by means of suggestion and contagion of feelings and ideas in an identical direction, the tendency immediately to transform the suggested ideas into acts; these, we see, are the principal characteristics of the individual forming part of a group. He is no longer himself, but has become an automaton who has ceased to be guided by his will" (p. 35).

I have quoted this passage so fully in order to make it quite clear that Le Bon explains the condition of an individual in a group as being actually hypnotic, and does not merely make a comparison between the two states. We have no intention of raising any objection at this point, but wish only to emphasize the fact that the two last causes of an individual becoming altered in a group (the contagion and the heightened suggestibility) are evidently not on a par, since the contagion seems actually to be a manifestation of the suggestibility. Moreover the effects of the two factors do not seem to be sharply differentiated in the text of Le Bon's remarks. We may perhaps best interpret his statement if we connect the contagion with the effects of the individual members of the group upon one another, while we point to another source for those manifestations of suggestion in the group which are put on a level with the phenomena of hypnotic influence. But to what source? We cannot avoid being struck with a sense of deficiency when we notice that one of the chief elements of the comparison, namely the person who is to replace the hypnotist in the case of the group, is not mentioned in Le Bon's exposition. But he nevertheless distinguishes between this influence of fascination which remains plunged in obscurity and the contagious effect which the individuals exercise upon one another and by which the original suggestion is strengthened.

Here is yet another important consideration for helping us to understand the individual in a group: "Moreover, by the mere fact that he forms part of an organized group, a man descends several rungs in the ladder of civilization. Isolated, he may be a cultivated individual; in a crowd he is a barbarian—that is, a creature acting by instinct. He possesses the spontaneity, the violence, the ferocity, and also the enthusiasm and heroism of primitive be-

ings" (p. 36). He then dwells especially upon the lowering in intellectual ability which an individual experiences when he becomes merged in a group.<sup>1</sup>

Let us now leave the individual, and turn to the group mind, as it has been outlined by Le Bon. It shows not a single feature which a psycho-analyst would find any difficulty in placing or in deriving from its source. Le Bon himself shows us the way by pointing to its similarity with the mental life of primitive people and of children (p. 40).

A group is impulsive, changeable, and irritable. It is led almost exclusively by the unconscious.<sup>2</sup> The impulses which a group obeys may according to circumstances be generous or cruel, heroic or cowardly, but they are always so imperious that no personal interest, not even that of self-preservation, can make itself felt (p. 41). Nothing about it is premeditated. Though it may desire things passionately, yet this is never so for long, for it is incapable of perseverance. It cannot tolerate any delay between its desire and the fulfilment of what it desires. It has a sense of omnipotence; the notion of impossibility disappears for the individual in a group.<sup>3</sup>

A group is extraordinarily credulous and open to influence, it has no critical faculty, and the improbable does not exist for it. It thinks in images, which call one another up by association (just as they arise with individuals in states of free imagination), and whose agreement with reality is never checked by any reasonable function (*Instanz*). The feelings of a group are always very simple and very exaggerated. So that a group knows neither doubt nor uncertainty.<sup>4</sup>

<sup>1</sup> Compare Schiller's couplet:

*"Jeder, sieht man ihn einzeln, ist leidlich klug und verständig;*

*Sind sie in corpore, gleich wird euch ein Dummkopf daraus."*

[Everyone, seen by himself, is passably shrewd and discerning;

*When they're in corpore, then straightway you'll find he's an ass.]—TR.*

<sup>2</sup> Unconscious is used here correctly by Le Bon in the descriptive sense, where it does not only mean the repressed.

<sup>3</sup> Compare *Totem and Taboo*, III, "Animism, Magic, and the Omnipotence of Thought."

<sup>4</sup> In the interpretation of dreams, to which, indeed, we owe our best knowledge of unconscious mental life, we follow a technical rule of disregarding doubt and uncertainty in the narrative of the dream, and of treating every element of the manifest dream as being quite certain. We attribute doubt and uncertainty to the influence of the censorship to which the dream-work is subjected, and we assume that the primary dream-thoughts are not acquainted with doubt and uncertainty as critical processes. They may naturally

It goes directly to extremes; if a suspicion is expressed, it is instantly changed into an incontrovertible certainty; a trace of antipathy is turned into furious hatred (p. 56).<sup>1</sup>

Inclined as it itself is to all extremes, a group can only be excited by an excessive stimulus. Anyone who wishes to produce an effect upon it needs no logical adjustment in his arguments; he must paint in the most forcible colours, he must exaggerate, and he must repeat the same thing again and again.

Since a group is in no doubt as to what constitutes truth or error, and is conscious, moreover, of its own great strength, it is as intolerant as it is obedient to authority. It respects force and can only be slightly influenced by kindness, which it regards merely as a form of weakness. What it demands of its heroes is strength, or even violence. It wants to be ruled and oppressed and to fear its masters. Fundamentally it is entirely conservative, and it has a deep aversion from all innovations and advances and an unbounded respect for tradition (p. 62).

In order to make a correct judgment upon the morals of groups, one must take into consideration the fact that when individuals come together in a group all their individual inhibitions fall away and all the cruel, brutal, and destructive instincts, which lie dormant in individuals as relics of a primitive epoch, are stirred up to find free gratification. But under the influence of suggestion, groups are also capable of high achievements in the shape of abnegation, unselfishness, and devotion to an ideal. While with isolated individuals personal interest is almost the only motive force, with groups it is very rarely prominent. It is possible to speak of an individual having his moral standards raised by a group (p. 65). Whereas the intellectual capacity of a group is always far below that of an individual, its ethical con-

duct may rise as high above his as it may sink deep below it.

Some other features in Le Bon's description show in a clear light how well justified is the identification of the group mind with the mind of primitive people. In groups the most contradictory ideas can exist side by side and tolerate each other, without any conflict arising from the logical contradiction between them. But this is also the case in the unconscious mental life of individuals, of children, and of neurotics, as psycho-analysis has long pointed out.<sup>2</sup>

A group, further, is subject to the truly magical power of words; they can evoke the most formidable tempests in the group mind, and are also capable of stilling them (p. 117). "Reason and arguments are incapable of combating certain words and formulas. They are uttered with solemnity in the presence of groups, and as soon as they have been pronounced an expression of respect is visible on every countenance, and all heads are bowed. By many they are considered as natural forces, as supernatural powers" (p. 117). It is only necessary in this connection to remember the taboo upon names among primitive people and the magical powers which they ascribe to names and words.<sup>3</sup>

And, finally, groups have never thirsted after truth. They demand illusions, and cannot do without them. They constantly give what is

<sup>2</sup> In young children, for instance, ambivalent emotional attitudes towards those who are nearest to them exist side by side for a long time, without either of them interfering with the expression of the other and contrary one. If eventually a conflict breaks out between the two, it is often settled by the child making a change of object and displacing one of the ambivalent emotions on to a substitute. The history of the development of a neurosis in an adult will also show that a suppressed emotion may frequently persist for a long time in unconscious or even in conscious phantasies, the content of which naturally runs directly counter to some predominant tendency, and yet that this antagonism does not result in any proceedings on the part of the ego against what it has repudiated. The phantasy is tolerated for quite a long time, until suddenly one day, usually as a result of an increase in the affective cathexis of the phantasy, a conflict breaks out between it and the ego with all the usual consequences. In the process of a child's development into a mature adult, there is a more and more extensive integration of its personality, a co-ordination of the separate instinctive feelings and desires which have grown up in him independently of one another. The analogous process in the domain of sexual life has long been known to us as the co-ordination of all the sexual instincts into a definitive genital organization. (*Three Contributions to the Sexual Theory*, Nervous and Mental Disease Monograph Series, No. 7, 1910.) Moreover, that the unification of the ego is liable to the same interferences as that of the libido is shown by numerous familiar instances, such as that of men of science who have preserved their faith in the Bible, and the like.

<sup>3</sup> See *Totem and Taboo*.

be present, like everything else, as part of the content of the day's residue which leads to the dream. See *The Interpretation of Dreams*, p. 343 above.

<sup>1</sup> The same extreme and unmeasured intensification of every emotion is also a feature of the affective life of children, and it is present as well in dream life. Thanks to the isolation of the single emotions in the unconscious, a slight annoyance during the day will express itself in a dream as a wish for the offending person's death, or a breath of temptation may give the impetus to the portrayal in the dream of a criminal action. Hanns Sachs has made an appropriate remark on this point: "If we try to discover in consciousness all that the dream has made known to us of its bearing upon the present (upon reality), we need not be surprised that what we saw as a monster under the microscope of analysis now reappears as an infusorium." *The Interpretation of Dreams*, p. 386 above.

unreal precedence over what is real; they are almost as strongly influenced by what is untrue as by what is true. They have an evident tendency not to distinguish between the two (p. 77).

We have pointed out that this predominance of the life of phantasy and of the illusion born of an unfulfilled wish is the ruling factor in the psychology of neuroses. We have found that what neurotics are guided by is not ordinary objective reality but psychological reality. A hysterical symptom is based upon phantasy instead of upon the repetition of real experience, and the sense of guilt in an obsessional neurosis is based upon the fact of an evil intention which was never carried out. Indeed, just as in dreams and in hypnosis, in the mental operations of a group the function for testing the reality of things falls into the background in comparison with the strength of wishes with their affective cathexis.

What Le Bon says on the subject of leaders of groups is less exhaustive, and does not enable us to make out an underlying principle so clearly. He thinks that as soon as living beings are gathered together in certain numbers, no matter whether they are a herd of animals or a collection of human beings, they place themselves instinctively under the authority of a chief (p. 134). A group is an obedient herd, which could never live without a master. It has such a thirst for obedience that it submits instinctively to anyone who appoints himself its master.

Although in this way the needs of a group carry it half-way to meet the leader, yet he too must fit in with it in his personal qualities. He must himself be held in fascination by a strong faith (in an idea) in order to awaken the group's faith; he must possess a strong and imposing will, which the group, which has no will of its own, can accept from him. Le Bon then discusses the different kinds of leaders, and the means by which they work upon the group. On the whole, he believes that the leaders make themselves felt by means of the ideas in which they themselves are fanatical believers.

Moreover, he ascribes both to the ideas and to the leaders a mysterious and irresistible power, which he calls *prestige*. Prestige is a sort of domination exercised over us by an individual, a work or an idea. It entirely paralyzes our critical faculty, and fills us with astonishment and respect. It would seem to arouse a feeling like that of fascination in hypnosis (p. 148).

He distinguishes between acquired or artificial and personal prestige. The former is attached to persons in virtue of their name, fortune, and reputation, and to opinions, works of art, etc., in virtue of tradition. Since in every case it harks back to the past, it cannot be of much help to us in understanding this puzzling influence. Personal prestige is attached to a few people, who become leaders by means of it, and it has the effect of making everything obey them as though by the operation of some magnetic magic. All prestige, however, is also dependent upon success, and is lost in the event of failure (p. 159).

We cannot feel that Le Bon has brought the function of the leader and the importance of prestige completely into harmony with his brilliantly executed picture of the group mind.

### III. OTHER ACCOUNTS OF COLLECTIVE MENTAL LIFE

WE have made use of Le Bon's description by way of introduction, because it fits in so well with our own psychology in the emphasis which it lays upon unconscious mental life. But we must now add that as a matter of fact none of that author's statements bring forward anything new. Everything that he says to the detriment and depreciation of the manifestations of the group mind had already been said by others before him with equal distinctness and equal hostility, and has been repeated in unison by thinkers, statesmen, and writers since the earliest periods of literature.<sup>1</sup> The two theses which comprise the most important of Le Bon's opinions, those touching upon the collective inhibition of intellectual functioning and the heightening of affectivity in groups, had been formulated shortly before by Sighele.<sup>2</sup> At bottom, all that is left over as being peculiar to Le Bon are the two notions of the unconscious and of the comparison with the mental life of primitive people, and even these had naturally often been alluded to before him.

But, what is more, the description and estimate of the group mind as they have been given by Le Bon and the rest have not by any means been left undisputed. There is no doubt that all the phenomena of the group mind which have just been mentioned have been correctly ob-

<sup>1</sup> B. Krasković jun.: *Die Psychologie der Kollektivitäten*, translated (into German) from the Croatian by Siegmund von Posavec, Vukovar, 1915. See the body of the work as well as the bibliography.

<sup>2</sup> See Walter Moede "Die Massen- und Sozialpsychologie im kritischen Überblick," Meumann and Scheibner's *Zeitschrift für pädagogische Psychologie und experimentelle Pädagogik*, 1915, xvi.

served, but it is also possible to distinguish other manifestations of the group formation, which operate in a precisely opposite sense, and from which a much higher opinion of the group mind must necessarily follow.

Le Bon himself was prepared to admit that in certain circumstances the morals of a group can be higher than those of the individuals that compose it, and that only collectivities are capable of a high degree of unselfishness and devotion. "While with isolated individuals personal interest is almost the only motive force, with groups it is very rarely prominent" (p. 65). Other writers adduce the fact that it is only society which prescribes any ethical standards at all for the individual, while he as a rule fails in one way or another to come up to its high demands. Or they point out that in exceptional circumstances there may arise in communities the phenomenon of enthusiasm, which has made the most splendid group achievements possible.

As regards intellectual work, it remains a fact, indeed, that great decisions in the realm of thought and momentous discoveries and solutions of problems are only possible to an individual, working in solitude. But even the group mind is capable of genius in intellectual creation, as is shown above all by language itself, as well as by folk-song, folk-lore and the like. It remains an open question, moreover, how much the individual thinker or writer owes to the stimulation of the group in which he lives, or whether he does more than perfect a mental work in which the others have had a simultaneous share.

In face of these completely contradictory accounts, it looks as though the work of group psychology were bound to come to an ineffectual end. But it is easy to find a more hopeful escape from the dilemma. A number of very different formations have probably been merged under the term *group* and may require to be distinguished. The assertions of Sighele, Le Bon and the rest relate to groups of a short-lived character, which some passing interest has hastily agglomerated out of various sorts of individuals. The characteristics of revolutionary groups, and especially those of the great French Revolution, have unmistakably influenced their descriptions. The opposite opinions owe their origin to the consideration of those stable groups or associations in which mankind pass their lives, and which are embodied in the institutions of society. Groups of the first kind stand in the same sort of relation to those of

the second as a high but choppy sea to a ground swell.

McDougall, in his book on *The Group Mind*,<sup>1</sup> starts out from the same contradiction that has just been mentioned, and finds a solution for it in the factor of organization. In the simplest case, he says, the *group* possesses no organization at all, or one scarcely deserving the name. He describes a group of this kind as a *crowd*. But he admits that a crowd of human beings can hardly come together without possessing at all events the rudiments of an organization, and that precisely in these simple groups many of the fundamental facts of collective psychology can be observed with special ease (p. 22). Before the members of a random crowd of people can constitute something in the nature of a group in the psychological sense of the word, a condition has to be fulfilled; these individuals must have something in common with one another, a common interest in an object, a similar emotional bias in some situation or other, and ("consequently," I should like to interpolate) "some degree of reciprocal influence" (p. 23). The higher the degree of "this mental homogeneity," the more readily do the individuals form a psychological group, and the more striking are the manifestations of a group mind.

The most remarkable and also the most important result of the formation of a group is the "exaltation or intensification of emotion" produced in every member of it (p. 24). In McDougall's opinion, men's emotions are stirred in a group to a pitch that they seldom or never attain under other conditions; and it is a pleasurable experience for those who are concerned to surrender themselves so unreservedly to their passions and thus to become merged in the group and to lose the sense of the limits of their individuality. The manner in which individuals are thus carried away by a common impulse is explained by McDougall by means of what he calls the "principle of direct induction of emotion by way of the primitive sympathetic response" (p. 25), that is, by means of the emotional contagion with which we are already familiar. The fact is that the perception of the signs of an emotional state is calculated automatically to arouse the same emotion in the person who perceives them. The greater the number of people in whom the same emotion can be simultaneously observed, the stronger does this automatic compulsion grow. The individual loses his power of criticism and lets himself slip into the same emotion. But in so

<sup>1</sup> Cambridge University Press, 1920.

doing he increases the excitement of the other people, who had produced this effect upon him, and thus the emotional charge of the individuals becomes intensified by mutual interaction. Something is unmistakably at work in the nature of a compulsion to do the same as the others, to remain in harmony with the many. The coarser and simpler emotions are the more apt to spread through a group in this way (p. 39).

This mechanism for the intensification of emotion is favoured by some other influences which emanate from groups. A group impresses the individual with a sense of unlimited power and of insurmountable peril. For the moment, it replaces the whole of human society, which is the wielder of authority, whose punishments the individual fears, and for whose sake he has submitted to so many inhibitions. It is clearly perilous for him to put himself in opposition to it, and it will be safer to follow the example of those around him and perhaps even "hunt with the pack." In obedience to the new authority he may put his former conscience out of action, and so surrender to the attraction of the increased pleasure that is certainly obtained from the removal of inhibitions. On the whole, therefore, it is not so remarkable that we should see an individual in a group doing or approving things which he would have avoided in the normal conditions of life; and in this way we may even hope to clear up a little of the mystery which is so often covered by the enigmatic word *suggestion*.

McDougall does not dispute the thesis as to the collective inhibition of intelligence in groups (p. 41). He says that the minds of lower intelligence bring down those of a higher order to their own level. The latter are obstructed in their activity, because in general an intensification of emotion creates unfavourable conditions for sound intellectual work, and, further, because the individuals are intimidated by the group and their mental activity is not free, and because there is a lowering in each individual of his sense of responsibility for his own performances.

The judgment with which McDougall sums up the psychological behaviour of a simple "unorganized" group is no more friendly than that of Le Bon. Such a group "is excessively emotional, impulsive, violent, fickle, inconsistent, irresolute, and extreme in action, displaying only the coarser emotions and the less refined sentiments; extremely suggestible, careless in deliberation, hasty in judgment, incapable of

any but the simpler and imperfect forms of reasoning; easily swayed and led, lacking in self-consciousness, devoid of self-respect and of sense of responsibility, and apt to be carried away by the consciousness of its own force, so that it tends to produce all the manifestations we have learnt to expect of any irresponsible and absolute power. Hence its behaviour is like that of an unruly child or an untutored passionate savage in a strange situation, rather than like that of its average member; and in the worst cases it is like that of a wild beast, rather than like that of human beings" (p. 45).

Since McDougall contrasts the behaviour of a highly organized group with what has just been described, we shall be particularly interested to learn in what this organization consists, and by what factors it is produced. The author enumerates five "principal conditions" for raising collective mental life to a higher level.

The first and fundamental condition is that there should be some degree of continuity of existence in the group. This may be either material or formal: the former, if the same individuals persist in the group for some time; and the latter, if there is developed within the group a system of fixed positions which are occupied by a succession of individuals.

The second condition is that in the individual member of the group some definite idea should be formed of the nature, composition, functions, and capacities of the group, so that from this he may develop an emotional relation to the group as a whole.

The third is that the group should be brought into interaction (perhaps in the form of rivalry) with other groups similar to it but differing from it in many respects.

The fourth is that the group should possess traditions, customs, and habits, and especially such as determine the relations of its members to one another.

The fifth is that the group should have a definite structure, expressed in the specialization and differentiation of the functions of its constituents.

According to McDougall, if these conditions are fulfilled, the psychological disadvantages of the group formation are removed. The collective lowering of intellectual ability is avoided by withdrawing the performance of intellectual tasks from the group and reserving them for individual members of it.

It seems to us that the condition which McDougall designates as the "organization" of

a group can with more justification be described in another way. The problem consists in how to procure for the group precisely those features which were characteristic of the individual and which are extinguished in him by the formation of the group. For the individual, outside the primitive group, possessed his own continuity, his self-consciousness, his traditions and customs, his own particular functions and position, and kept apart from his rivals. Owing to his entry into an "unorganized" group, he had lost this distinctiveness for a time. If we thus recognize that the aim is to equip the group with the attributes of the individual, we shall be reminded of a valuable remark of Trotter's,<sup>1</sup> to the effect that the tendency towards the formation of groups is biologically a continuation of the multicellular character of all the higher organisms.

#### IV. SUGGESTION AND LIBIDO

WE started from the fundamental fact that an individual in a group is subjected through its influence to what is often a profound alteration in his mental activity. His emotions become extraordinarily intensified, while his intellectual ability becomes markedly reduced, both processes being evidently in the direction of an approximation to the other individuals in the group; and this result can only be reached by the removal of those inhibitions upon his instincts which are peculiar to each individual, and by his resigning those expressions of his inclinations which are especially his own. We have heard that these often unwelcome consequences are to some extent at least prevented by a higher "organization" of the group; but this does not contradict the fundamental fact of group psychology—the two theses as to the intensification of the emotions and the inhibition of the intellect in primitive groups. Our interest is now directed to discovering the psychological explanation of this mental change which is experienced by the individual in a group.

It is clear that rational factors (such as the intimidation of the individual which has already been mentioned, that is, the action of his instinct of self-preservation) do not cover the observable phenomena. Beyond this, what we are offered as an explanation by authorities upon sociology and group psychology is always the same, even though it is given various names, and that is—the magic word *suggestion*. Tarde

calls it "imitation"; but we cannot help agreeing with a writer who protests that imitation comes under the concept of suggestion, and is in fact one of its results.<sup>2</sup> Le Bon traces back all the puzzling features of social phenomena to two factors: the mutual suggestion of individuals and the prestige of leaders. But prestige, again, is only recognizable by its capacity for evoking suggestion. McDougall for a moment gives us an impression that his principle of "primitive induction of emotion" might enable us to do without the assumption of suggestion. But on further consideration we are forced to perceive that this principle says no more than the familiar assertions about "imitation" or "contagion," except for a decided stress upon the emotional factor. There is no doubt that something exists in us which, when we become aware of signs of an emotion in someone else, tends to make us fall into the same emotion; but how often do we not successfully oppose it, resist the emotion, and react in quite an opposite way? Why, therefore, do we invariably give way to this contagion when we are in a group? Once more we should have to say that what compels us to obey this tendency is imitation, and what induces the emotion in us is the group's suggestive influence. Moreover, quite apart from this, McDougall does not enable us to evade suggestion; we hear from him as well as from other writers that groups are distinguished by their special suggestibility.

We shall therefore be prepared for the statement that suggestion (or more correctly suggestibility) is actually an irreducible, primitive phenomenon, a fundamental fact in the mental life of man. Such, too, was the opinion of Bernheim, of whose astonishing arts I was a witness in the year 1889. But I can remember even then feeling a muffled hostility to this tyranny of suggestion. When a patient who showed himself unamenable was met with the shout: "*What are you doing? Vous vous contresuggestionnez!*" I said to myself that this was an evident injustice and an act of violence. For the man certainly had a right to counter-suggestions if they were trying to subdue him with suggestions. Later on, my resistance took the direction of protesting against the view that suggestion, which explained everything, was itself to be preserved from explanation. Thinking of it, I repeated the old conundrum:<sup>3</sup>

<sup>2</sup> Bruguilles, "*L'Essence du phénomène social: la suggestion*," *Revue philosophique*, 1913, xxv.

<sup>3</sup> Konrad Richter, "*Der deutsche S. Christoph*," Berlin, 1896, *Acta Germanica*, v, 1.

<sup>1</sup> *Instincts of the Herd in Peace and War*, Fisher Unwin, 1916.

*Christoph trug Christum,  
Christus trug die ganze Welt,  
Sag' wo hat Christoph  
Damals hin den Fuss gestellt?¹*

*Christophorus Christum, sed Christus sustulit orbem:*

*Constititit pedibus dic ubi Christophorus?*

Now that I once more approach the riddle of suggestion after having kept away from it for some thirty years, I find there is no change in the situation. To this statement I can discover only a single exception, which I need not mention, since it is one which bears witness to the influence of psycho-analysis. I notice that particular efforts are being made to formulate the concept of suggestion correctly, that is, to fix the conventional use of the name.<sup>2</sup> And this is by no means superfluous, for the word is acquiring a more and more extended use and a looser and looser meaning, and will soon come to designate any sort of influence whatever, just as in English, where "to suggest" and "suggestion" correspond to our *nachelegen* and *Anregung*. But there has been no explanation of the nature of suggestion, that is, of the conditions under which influence without adequate logical foundation takes place. I should not avoid the task of supporting this statement by an analysis of the literature of the last thirty years, if I were not aware that an exhaustive inquiry is being undertaken close at hand which has in view the fulfilment of this very task.

Instead of this, I shall make an attempt at using the concept of *libido* for the purpose of throwing light upon group psychology, a concept which has done us such good service in the study of psychoneuroses.

*Libido* is an expression taken from the theory of the emotions. We call by that name the energy (regarded as a quantitative magnitude, though not at present actually measurable) of those instincts which have to do with all that may be comprised under the word *love*. The nucleus of what we mean by love naturally consists (and this is what is commonly called love, and what the poets sing of) in sexual love with sexual union as its aim. But we do not separate from this—what in any case has a share in the name *love*—on the one hand, self-love, and on the other, love for parents and children, friendship, and love for humanity in general, and also

devotion to concrete objects and to abstract ideas. Our justification lies in the fact that psycho-analytic research has taught us that all these tendencies are an expression of the same instinctive activities; in relations between the sexes these instincts force their way towards sexual union, but in other circumstances they are diverted from this aim or are prevented from reaching it, though always preserving enough of their original nature to keep their identity recognizable (as in such features as the longing for proximity, and self-sacrifice).

We are of opinion, then, that language has carried out an entirely justifiable piece of unification in creating the word *love* with its numerous uses, and that we cannot do better than take it as the basis of our scientific discussions and expositions as well. By coming to this decision, psycho-analysis has let loose a storm of indignation, as though it had been guilty of an act of outrageous innovation. Yet psycho-analysis has done nothing original in taking love in this "wider" sense. In its origin, function, and relation to sexual love, the "*Eros*" of the philosopher Plato coincides exactly with the love force, the libido, of psycho-analysis, as has been shown in detail by Nachmansohn and Pfister;<sup>3</sup> and when the apostle Paul, in his famous epistle to the Corinthians, prizes love above all else, he certainly understands it in the same "wider" sense.<sup>4</sup> But this only shows that men do not always take their great thinkers seriously, even when they profess most to admire them.

Psycho-analysis, then, gives these love instincts the name of sexual instincts, a *potiori* and by reason of their origin. The majority of "educated" people have regarded this nomenclature as an insult, and have taken their revenge by retorting upon psycho-analysis with the reproach of "pan-sexualism." Anyone who considers sex as something mortifying and humiliating to human nature is at liberty to make use of the more genteel expressions "*Eros*" and "erotic." I might have done so myself from the first and thus have spared myself much opposition. But I did not want to, for I like to avoid concessions to faint-heartedness. One can never tell where that road may lead one; one gives way first in words, and then little by little in substance too. I cannot see any merit in being

<sup>3</sup> Nachmansohn, "*Freuds Libidotheorie verglichen mit der Eroslehre Platos*," *Internationale Zeitschrift für Psychoanalyse*, 1915, Vol. III; Pfister, "Plato: a Fore-Runner of Psycho-Analysis," *International Journal of Psycho-Analysis*, 1922, Vol. III.

<sup>4</sup> "Though I speak with the tongues of men and of angels, and have not love, I am become as sounding brass, or a tinkling cymbal."

<sup>1</sup> Literally: "Christopher bore Christ; Christ bore the whole world; Say, where did Christopher then put his foot?"—Tr.

<sup>2</sup> Thus, McDougall: "A Note on Suggestion," *Journal of Neurology and Psychopathology*, 1920, Vol. I, No. 1.

ashamed of sex; the Greek word *Eros*, which is to soften the affront, is in the end nothing more than a translation of our German word *Liebe*; and finally, he who knows how to wait need make no concessions.

We will try our fortune, then, with the supposition that love relationships (or, to use a more neutral expression, emotional ties) also constitute the essence of the group mind. Let us remember that the authorities make no mention of any such relations. What would correspond to them is evidently concealed behind the shelter, the screen, of suggestion. Our hypothesis finds support in the first instance from two passing thoughts: First, that a group is clearly held together by a power of some kind: and to what power could this feat be better ascribed than to *Eros*, who holds together everything in the world? Secondly, that if an individual gives up his distinctiveness in a group and lets its other members influence him by suggestion, it gives one the impression that he does it because he feels the need of being in harmony with them rather than in opposition to them—so that perhaps after all he does it *ihnen zu Liebe*.<sup>1</sup>

#### V. TWO ARTIFICIAL GROUPS: THE CHURCH AND THE ARMY

WE may recall from what we know of the morphology of groups that it is possible to distinguish very different kinds of groups and opposing lines in their development. There are very fleeting groups and extremely lasting ones; homogeneous ones, made up of the same sorts of individuals, and unhomogeneous ones; natural groups, and artificial ones, requiring an external force to keep them together; primitive groups, and highly organized ones with a definite structure. But for reasons which have yet to be explained we should like to lay particular stress upon a distinction to which the authorities have rather given too little attention; I refer to that between leaderless groups and those with leaders. And, in complete opposition to the usual practice, we shall not choose a relatively simple group formation as our point of departure, but shall begin with highly organized, lasting, and artificial groups. The most interesting example of such structures are churches—communities of believers—and armies.

A church and an army are artificial groups,

<sup>1</sup> An idiom meaning "for their sake." Literally: "for love of them."—TR.

that is, a certain external force is employed to prevent them from disintegrating and to check alterations in their structure. As a rule a person is not consulted, or is given no choice, as to whether he wants to enter such a group; any attempt at leaving it is usually met with persecution or with severe punishment, or has quite definite conditions attached to it. It is quite outside our present interest to enquire why these associations need such special safeguards. We are only attracted by one circumstance, namely that certain facts, which are far more concealed in other cases, can be observed very clearly in those highly organized groups which are protected from dissolution in the manner that has been mentioned.

In a church (and we may with advantage take the Catholic Church as a type) as well as in an army, however different the two may be in other respects, the same illusion holds good of there being a head—in the Catholic Church Christ, in an army its commander-in-chief—who loves all the individuals in the group with an equal love. Everything depends upon this illusion; if it were to be dropped, then both Church and army would dissolve, so far as the external force permitted them to. This equal love was expressly enunciated by Christ: "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." He stands to the individual members of the group of believers in the relation of a kind elder brother; he is their father surrogate. All the demands that are made upon the individual are derived from this love of Christ's. A democratic character runs through the Church, for the very reason that before Christ everyone is equal, and that everyone has an equal share in his love. It is not without a deep reason that the similarity between the Christian community and a family is invoked, and that believers call themselves *brothers in Christ*, that is, brothers through the love which Christ has for them. There is no doubt that the tie which unites each individual with Christ is also the cause of the tie which unites them with one another. The like holds good of an army. The commander-in-chief is a father who loves all his soldiers equally, and for that reason they are comrades among themselves. The army differs structurally from the Church in being built up of a series of such groups. Every captain is, as it were, the commander-in-chief and the father of his company, and so is every non-commissioned officer of his section. It is true that a similar

hierarchy has been constructed in the Church, but it does not play the same part in it economically; for more knowledge and care about individuals may be attributed to Christ than to a human commander-in-chief.<sup>1</sup>

It is to be noticed that in these two artificial groups each individual is bound by libidinal ties on the one hand to the leader (Christ, the commander-in-chief), and on the other hand to the other members of the group. How these two ties are related to each other, whether they are of the same kind and the same value, and how they are to be described psychologically—these questions must be reserved for subsequent enquiry. But we shall venture even now upon a mild reproach against the authorities for not having sufficiently appreciated the importance of the leader in the psychology of the group, while our own choice of a first object for investigation has brought us into a more favourable position. It would appear as though we were on the right road towards an explanation of the principal phenomenon of group psychology—the individual's lack of freedom in a group. If each individual is bound in two directions by such an intense emotional tie, we shall find no difficulty in attributing to that circumstance the alteration and limitation which have been observed in his personality.

A hint to the same effect, that the essence of a group lies in the libidinal ties existing in it, is also to be found in the phenomenon of panic,

<sup>1</sup> An objection will justly be raised against this conception of the libidinal structure of an army on the ground that no place has been found in it for such ideas as those of one's country, of national glory, etc. which are of such importance in holding an army together. The answer is that that is a different instance of a group tie, and no longer such a simple one; for the examples of great generals, like Caesar, Wallenstein, or Napoleon, show that such ideas are not indispensable to the existence of an army. We shall presently touch upon the possibility of a leading idea being substituted for a leader and upon the relations between the two. The neglect of this libidinal factor in an army, even when it is not the only factor operative, seems to be not merely a theoretical omission but also a practical danger. Prussian militarism, which was just as unpsychological as German science, may have had to suffer the consequences of this in the Great War. We know that the war neuroses which ravaged the German army have been recognized as being a protest of the individual against the part he was expected to play in the army; and according to the communication of E. Simmel (*Kriegsneurosen und "Psychisches Trauma,"* Munich, 1918), the hard treatment of the men by their superiors may be considered as foremost among the motive forces of the disease. If the importance of the libido's claims on this score had been better appreciated, the fantastic promises of the American President's fourteen points would probably not have been believed so easily, and the splendid instrument would not have broken in the hands of the German leaders.

which is best studied in military groups. A panic arises if a group of that kind becomes disintegrated. Its characteristics are that none of the orders given by superiors are any longer listened to, and that each individual is only solicitous on his own account, and without any consideration for the rest. The mutual ties have ceased to exist, and a gigantic and senseless dread (*Angst*) is set free. At this point, again, the objection will naturally be made that it is rather the other way round; and that the dread has grown so great as to be able to disregard all ties and all feelings of consideration for others. McDougall has even (p. 24) made use of the case of panic (though not of military panic) as a typical instance of that intensification of emotion by contagion ("primary induction") upon which he lays so much emphasis. But, nevertheless, this rational method of explanation is here quite inadequate. The very question that needs explanation is why the dread has become so gigantic. The greatness of the danger cannot be responsible, for the same army which now falls a victim to panic may previously have faced equally great or greater danger with complete success; it is of the very essence of panic that it bears no relation to the danger that threatens, and often breaks out upon the most trivial occasions. If an individual in panic dread begins to be solicitous only on his own account, he bears witness in so doing to the fact that the emotional ties, which have hitherto made the danger seem small to him, have ceased to exist. Now that he is by himself in facing the danger, he may surely think it greater. The fact is, therefore, that panic dread presupposes a relaxation in the libidinal structure of the group and reacts to it in a justifiable manner, and the contrary view—that the libidinal ties of the group are destroyed owing to dread in the face of the danger—can be refuted.

The contention that dread in a group is increased to enormous proportions by means of induction (contagion) is not in the least contradicted by these remarks. McDougall's view meets the case entirely when the danger is a really great one and when the group has no strong emotional ties—conditions which are fulfilled, for instance, when a fire breaks out in a theatre or a place of amusement. But the really instructive case and the one which can be best employed for our purposes is that mentioned above, in which a body of troops breaks into a panic although the danger has not increased beyond a degree that is usual and has

often been previously faced. It is not to be expected that the usage of the word *panic* should be clearly and unambiguously determined. Sometimes it is used to describe any collective dread, sometimes even dread in an individual when it exceeds all bounds, and often the name seems to be reserved for cases in which the outbreak of dread is not warranted by the occasion. If we take the word *panic* in the sense of collective dread, we can establish a far-reaching analogy. Dread in an individual is provoked either by the greatness of a danger or by the cessation of emotional ties (libidinal cathexes [*Libidobesetzungen*]); the latter is the case of neurotic dread.<sup>1</sup> In just the same way panic arises either owing to an increase of the common danger or owing to the disappearance of the emotional ties which hold the group together; and the latter case is analogous to that of neurotic dread.<sup>2</sup>

Anyone who, like McDougall (*op. cit.*), describes a panic as one of the plainest functions of the "group mind," arrives at the paradoxical position that this group mind does away with itself in one of its most striking manifestations. It is impossible to doubt that panic means the disintegration of a group; it involves the cessation of all the feelings of consideration which the members of the group otherwise show one another.

The typical occasion of the outbreak of a panic is very much as it is represented in Nestroy's parody of Hebbel's play about Judith and Holofernes. A soldier cries out: "The general has lost his head!" and thereupon all the Assyrians take to flight. The loss of the leader in some sense or other, the birth of misgivings about him, brings on the outbreak of panic, though the danger remains the same; the mutual ties between the members of the group disappear, as a rule, at the same time as the tie with their leader. The group vanishes in dust, like a Bologna flask when its top is broken off.

The dissolution of a religious group is not so easy to observe. A short time ago there came into my hands an English novel of Catholic origin, recommended by the Bishop of London, with the title *When It Was Dark*. It gave a clever and, as it seems to me, a convincing picture of such a possibility and its consequences. The novel, which is supposed to relate to the present day, tells how a conspiracy of enemies

of the figure of Christ and of the Christian faith succeed in arranging for a sepulchre to be discovered in Jerusalem. In this sepulchre is an inscription, in which Joseph of Arimathea confesses that for reasons of piety he secretly removed the body of Christ from its grave on the third day after its entombment and buried it in this spot. The resurrection of Christ and his divine nature are by this means disposed of, and the result of this archaeological discovery is a convulsion in European civilization and an extraordinary increase in all crimes and acts of violence, which only ceases when the forgers' plot has been revealed.

The phenomenon which accompanies the dissolution that is here supposed to overtake a religious group is not dread, for which the occasion is wanting. Instead of it, ruthless and hostile impulses towards other people make their appearance, which, owing to the equal love of Christ, they had previously been unable to do.<sup>3</sup> But even during the kingdom of Christ those people who do not belong to the community of believers, who do not love him, and whom he does not love, stand outside this tie. Therefore a religion, even if it calls itself the religion of love, must be hard and unloving to those who do not belong to it. Fundamentally, indeed, every religion is in this same way a religion of love for all those whom it embraces; while cruelty and intolerance towards those who do not belong to it are natural to every religion. However difficult we may find it personally, we ought not to reproach believers too severely on this account; people who are unbelieving or indifferent are so much better off psychologically in this respect. If today that intolerance no longer shows itself so violent and cruel as in former centuries, we can scarcely conclude that there has been a softening in human manners. The cause is rather to be found in the undeniable weakening of religious feelings and the libidinal ties which depend upon them. If another group tie takes the place of the religious one—and the socialistic tie seems to be succeeding in doing so—then there will be the same intolerance towards outsiders as in the age of the Wars of Religion; and if differences between scientific opinions could ever attain a similar significance for groups, the same result would again be repeated with this new motivation.

<sup>1</sup> *General Introduction to Psycho-Analysis*, Lecture xxv, p. 607 above.

<sup>2</sup> Compare Bela v. Felszeghy's interesting though somewhat fantastic paper "*Panik und Pankomplex*," *Imago*, 1920, Vol. VI.

<sup>3</sup> Compare the explanation of similar phenomena after the abolition of the paternal authority of the sovereign given in P. Federn's *Die vaterlose Gesellschaft*, Vienna, Anzengruber-Verlag, 1919.

## VI. FURTHER PROBLEMS AND LINES OF WORK

WE have hitherto considered two artificial groups and have found that they are dominated by two emotional ties. One of these, the tie with the leader, seems (at all events for these cases) to be more of a ruling factor than the other, which holds between the members of the group.

Now much else remains to be examined and described in the morphology of groups. We should have to start from the ascertained fact that a mere collection of people is not a group, so long as these ties have not been established in it; but we should have to admit that in any collection of people the tendency to form a psychological group may very easily become prominent. We should have to give our attention to the different kinds of groups, more or less stable, that arise spontaneously, and to study the conditions of their origin and of their dissolution. We should above all be concerned with the distinction between groups which have a leader and leaderless groups. We should consider whether groups with leaders may not be the more primitive and complete, whether in the others an idea, an abstraction, may not be substituted for the leader (a state of things to which religious groups, with their invisible head, form a transition stage), and whether a common tendency, a wish in which a number of people can have a share, may not in the same way serve as a substitute. This abstraction, again, might be more or less completely embodied in the figure of what we might call a *secondary* leader, and interesting varieties would arise from the relation between the idea and the leader. The leader or the leading idea might also, so to speak, be negative; hatred against a particular person or institution might operate in just the same unifying way, and might call up the same kind of emotional ties as positive attachment. Then the question would also arise whether a leader is really indispensable to the essence of a group—and other questions besides.

But all these questions, which may, moreover, have been dealt with in part in the literature of group psychology, will not succeed in diverting our interest from the fundamental psychological problems that confront us in the structure of a group. And our attention will first be attracted by a consideration which promises to bring us in the most direct way to a proof that libidinal ties are what characterize a group.

Let us keep before our eyes the nature of the

emotional relations which hold between men in general. According to Schopenhauer's famous simile of the freezing porcupines, no one can tolerate a too intimate approach to his neighbour.<sup>1</sup>

The evidence of psycho-analysis shows that almost every intimate emotional relation between two people which lasts for some time—marriage, friendship, the relations between parents and children<sup>2</sup>—leaves a sediment of feelings of aversion and hostility, which have first to be eliminated by repression. This is less disguised in the common wrangles between business partners or in the grumbles of a subordinate at his superior. The same thing happens when men come together in larger units. Every time two families become connected by a marriage, each of them thinks itself superior to or of better birth than the other. Of two neighbouring towns, each is the other's most jealous rival; every little canton looks down upon the others with contempt. Closely related races keep one another at arm's length; the South German cannot endure the North German, the Englishman casts every kind of aspersions upon the Scotchman, the Spaniard despises the Portuguese. We are no longer astonished that greater differences should lead to an almost insuperable repugnance, such as the Gallic people feel for the German, the Aryan for the Semite, and the white races for the coloured.

When this hostility is directed against people who are otherwise loved, we describe it as *ambivalence* of feeling; and we explain the fact, in what is probably far too rational a manner, by means of the numerous occasions for conflicts of interest which arise precisely in such intimate relations. In the undisguised antipathies and aversions which people feel towards strangers with whom they have to do, we may recognize the expression of self-love—of narcissism. This self-love works for the self-assertion of the individual, and behaves as

<sup>1</sup> "A company of porcupines crowded themselves very closely together one cold winter's day so as to profit by one another's warmth and so save themselves from being frozen to death. But soon they felt one another's quills, which induced them to separate again. And now, when the need for warmth brought them nearer together again, the second evil arose once more. So that they were driven backwards and forwards from one trouble to the other, until they had discovered a mean distance at which they could most tolerably exist." *Parerga und Paralipomena*, Part II, xxxi, "*Gleichnisse und Parabeln*."

<sup>2</sup> Perhaps with the solitary exception of the relation of a mother to her son, which is based upon narcissism, is not disturbed by subsequent rivalry, and is reinforced by a rudimentary attempt at sexual object-choice.

though the occurrence of any divergence from his own particular lines of development involved a criticism of them and a demand for their alteration. We do not know why such sensitiveness should have been directed to just these details of differentiation; but it is unmistakable that in this whole connection men give evidence of a readiness for hatred, an aggressiveness, the source of which is unknown, and to which one is tempted to ascribe an elementary character.<sup>1</sup>

But the whole of this intolerance vanishes, temporarily or permanently, as the result of the formation of a group, and in a group. So long as a group formation persists or so far as it extends, individuals behave as though they were uniform, tolerate other people's peculiarities, put themselves on an equal level with them, and have no feeling of aversion towards them. Such a limitation of narcissism can, according to our theoretical views, only be produced by one factor, a libidinal tie with other people. Love for oneself knows only one barrier—love for others, love for objects.<sup>2</sup> The question will at once be raised whether community of interest in itself, without any addition of libido, must not necessarily lead to the toleration of other people and to considerateness for them. This objection may be met by the reply that nevertheless no lasting limitation of narcissism is effected in this way, since this tolerance does not persist longer than the immediate advantage gained from the other people's collaboration. But the practical importance of the discussion is less than might be supposed, for experience has shown that in cases of collaboration libidinal ties are regularly formed between the fellow-workers which prolong and solidify the relation between them to a point beyond what is merely profitable. The same thing occurs in men's social relations as has become familiar to psycho-analytic research in the course of the development of the individual libido. The libido props itself upon the satisfaction of the great vital needs, and chooses as its first objects the people who have a share in that process. And in the development of mankind as a whole, just as in individuals, love alone acts as the civilizing factor in the sense that it brings a change from egoism to altruism. And this is true both of the sexual love for women, with all the obligations which it in-

volves of sparing what women are fond of, and also of the desexualised, sublimated homosexual love for other men, which springs from work in common.

If therefore in groups narcissistic self-love is subject to limitations which do not operate outside them, that is cogent evidence that the essence of a group formation consists in a new kind of libidinal ties among the members of the group.

But our interest now leads us on to the pressing question as to what may be the nature of these ties which exist in groups. In the psycho-analytic study of neuroses we have hitherto been occupied almost exclusively with ties that unite with their objects those love instincts which still pursue directly sexual aims. In groups there can evidently be no question of sexual aims of that kind. We are concerned here with love instincts which have been diverted from their original aims, though they do not operate with less energy on that account. Now we have already observed within the range of the usual sexual object-cathexis (*Objektbesetzung*) phenomena which represent a diversion of the instinct from its sexual aim. We have described them as degrees of being in love, and have recognized that they involve a certain encroachment upon the ego. We shall now turn our attention more closely to these phenomena of being in love, in the firm expectation of finding in them conditions which can be transferred to the ties that exist in groups. But we should also like to know whether this kind of object-cathexis, as we know it in sexual life, represents the only manner of emotional tie with other people, or whether we must take other mechanisms of the sort into account. As a matter of fact we learn from psycho-analysis that there do exist other mechanisms for emotional ties, the so-called *identifications*, insufficiently-known processes and hard to describe, the investigation of which will for some time keep us away from the subject of group psychology.

## VII. IDENTIFICATION

IDENTIFICATION is known to psycho-analysis as the earliest expression of an emotional tie with another person. It plays a part in the early history of the Oedipus complex. A little boy will exhibit a special interest in his father; he would like to grow like him and be like him, and take his place everywhere. We may say simply that he takes his father as his ideal. This behaviour has nothing to do with a passive or feminine attitude towards his father (and towards males

<sup>1</sup> In a recently published study, *Beyond the Pleasure Principle* [p. 639 above], I have attempted to connect the polarity of love and hatred with a hypothetical opposition between instincts of life and death, and to establish the sexual instincts as the purest examples of the former, the instincts of life.

<sup>2</sup> See *On Narcissism: an Introduction*, p. 399 above.

in general); it is on the contrary typically masculine. It fits in very well with the Oedipus complex, for which it helps to prepare the way.

At the same time as this identification with his father, or a little later, the boy has begun to develop a true object-cathexis towards his mother according to the anaclitic type. He then exhibits, therefore, two psychologically distinct ties: a straightforward sexual object-cathexis towards his mother and a typical identification towards his father. The two subsist side by side for a time without any mutual influence or interference. In consequence of the irresistible advance towards a unification of mental life, they come together at last; and the normal Oedipus complex originates from their confluence. The little boy notices that his father stands in his way with his mother. His identification with his father then takes on a hostile colouring and becomes identical with the wish to replace his father in regard to his mother as well. Identification, in fact, is ambivalent from the very first; it can turn into an expression of tenderness as easily as into a wish for someone's removal. It behaves like a derivative of the first *oral* phase of the organization of the libido, in which the object that we long for and prize is assimilated by eating and is in that way annihilated as such. The cannibal, as we know, has remained at this standpoint; he has a devouring affection for his enemies and only devours people of whom he is fond.<sup>1</sup>

The subsequent history of this identification with the father may easily be lost sight of. It may happen that the Oedipus complex becomes inverted, and that the father is taken as the object of a feminine attitude, an object from which the directly sexual instincts look for satisfaction; in that event, the identification with the father has become the precursor of an object tie with the father. The same holds good, with the necessary substitutions, of the baby daughter as well.

It is easy to state in a formula the distinction between an identification with the father and the choice of the father as an object. In the first case, one's father is what one would like to *be*; and, in the second, he is what one would like to *have*. The distinction, that is, depends upon whether the tie attaches to the subject or to the object of the ego. The former is there-

fore already possible before any sexual object-choice has been made. It is much more difficult to give a clear metapsychological representation of the distinction. We can only see that identification endeavours to mould a person's own ego after the fashion of the one that has been taken as a *model*.

Let us disentangle identification as it occurs in the structure of a neurotic symptom from its rather complicated connections. Supposing that a little girl (and we will keep to her for the present) develops the same painful symptom as her mother—for instance, the same tormenting cough. Now this may come about in various ways. The identification may come from the Oedipus complex; in that case it signifies a hostile desire on the girl's part to take her mother's place, and the symptom expresses her object love towards her father, and brings about a realization, under the influence of a sense of guilt, of her desire to take her mother's place: "You wanted to be your mother, and now you *are*—anyhow as far as the pain goes." This is the complete mechanism of the structure of an hysterical symptom. Or, on the other hand, the symptom may be the same as that of the person who is loved—(so, for instance, Dora in the "Fragment of an Analysis of a Case of Hysteria,"<sup>2</sup> imitated her father's cough); in that case we can only describe the state of things by saying that *identification has appeared instead of object-choice, and that object-choice has regressed to identification*. We have heard that identification is the earliest and original form of emotional tie; it often happens that under the conditions in which symptoms are constructed, that is, where there is repression and where the mechanisms of the unconscious are dominant, object-choice is turned back into identification—the ego, that is, assumes the characteristics of the object. It is noticeable that in these identifications the ego sometimes copies the person who is not loved and sometimes the one who is loved. It must also strike us that in both cases the identification is a partial and extremely limited one and only borrows a single trait from the person who is its object.

There is a third particularly frequent and important case of symptom formation, in which the identification leaves any object relation to the person who is being copied entirely out of account. Supposing, for instance, that one of the girls in a boarding school has had a letter from someone with whom she is secretly in

<sup>1</sup> See *Three Contributions to the Theory of Sex*, and Abraham's "Untersuchungen über die früheste prägenitale Entwicklungsstufe der Libido," *Internationale Zeitschrift für Psychoanalyse*, 1916, Vol. IV; also included in his *Klinische Beiträge zur Psychoanalyse* (Internationale Psychoanalytische Bibliothek, No. 10, 1921).

<sup>2</sup> *Collected Papers*, III.

love which arouses her jealousy, and that she reacts to it with a fit of hysterics; then some of her friends who know about it will contract the fit, as we say, by means of mental infection. The mechanism is that of identification based upon the possibility or desire of putting oneself in the same situation. The other girls would like to have a secret love affair too, and under the influence of a sense of guilt they also accept the pain involved in it. It would be wrong to suppose that they take on the symptom out of sympathy. On the contrary, the sympathy only arises out of the identification, and this is proved by the fact that infection or imitation of this kind takes place in circumstances where even less pre-existing sympathy is to be assumed than usually exists between friends in a girls' school. One ego has perceived a significant analogy with another upon one point—in our example upon a similar readiness for emotion; an identification is thereupon constructed on this point, and, under the influence of the pathogenic situation, is displaced on to the symptom which the one ego has produced. The identification by means of the symptom has thus become the mark of a point of coincidence between the two egos which has to be kept repressed.

What we have learned from these three sources may be summarized as follows. First, identification is the original form of emotional tie with an object; secondly, in a regressive way it becomes a substitute for a libidinal object tie, as it were, by means of the introjection of the object into the ego; and thirdly, it may arise with every new perception of a common quality shared with some other person who is not an object of the sexual instinct. The more important this common quality is, the more successful may this partial identification become, and it may thus represent the beginning of a new tie.

We already begin to divine that the mutual tie between members of a group is in the nature of an identification of this kind, based upon an important emotional common quality; and we may suspect that this common quality lies in the nature of the tie with the leader. Another suspicion may tell us that we are far from having exhausted the problem of identification, and that we are faced by the process which psychology calls *empathy* (*Einfühlung*) and which plays the largest part in our understanding of what is inherently foreign to our ego in other people. But we shall here limit ourselves to the immediate emotional effects of identifica-

tion, and shall leave on one side its significance for our intellectual life.

Psycho-analytic research, which has already occasionally attacked the more difficult problems of the psychoses, has also been able to exhibit identification to us in some other cases which are not immediately comprehensible. I shall treat two of these cases in detail as material for our further consideration.

The genesis of male homosexuality in a large class of cases is as follows. A young man has been unusually long and intensely fixated upon his mother in the sense of the Oedipus complex. But at last, after the end of his puberty, the time comes for exchanging his mother for some other sexual object. Things take a sudden turn: the young man does not abandon his mother, but identifies himself with her; he transforms himself into her, and now looks about for objects which can replace his ego for him, and on which he can bestow such love and care as he has experienced from his mother. This is a frequent process, which can be confirmed as often as one likes, and which is naturally quite independent of any hypothesis that may be made as to the organic driving force and the motives of the sudden transformation. A striking thing about this identification is its ample scale; it remoulds the ego in one of its important features—in its sexual character—upon the model of what has hitherto been the object. In this process the object itself is renounced—whether entirely or in the sense of being preserved only in the unconscious is a question outside the present discussion. Identification with an object that is renounced or lost as a substitute for it, introjection of this object into the ego, is indeed no longer a novelty to us. A process of the kind may sometimes be directly observed in small children. A short time ago an observation of this sort was published in the *Internationale Zeitschrift für Psychoanalyse*. A child who was unhappy over the loss of a kitten declared straight out that now he himself was the kitten, and accordingly crawled about on all fours, would not eat at table, etc.<sup>1</sup>

Another such instance of introjection of the object has been provided by the analysis of melancholia, an affection which counts among the most remarkable of its exciting causes the real or emotional loss of a loved object. A leading characteristic of these cases is a cruel self-depreciation of the ego combined with relentless

<sup>1</sup> Marcuszewicz: "Beitrag zum autistischen Denken bei Kindern," *Internationale Zeitschrift für Psychoanalyse*, (1920), Vol. VI.

self-criticism and bitter self-reproaches. Analyses have shown that this disparagement and these reproaches apply at bottom to the object and represent the ego's revenge upon it. The shadow of the object has fallen upon the ego, as I have said elsewhere.<sup>1</sup> The introjection of the object is here unmistakably clear.

But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical faculty (*Instanz*) within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions we have been driven to the hypothesis<sup>2</sup> that some such faculty develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the *ego ideal*, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego found its self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this faculty has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents.<sup>3</sup> But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

But before we can employ this material for understanding the libidinal organization of groups, we must take into account some other examples of the mutual relations between the object and the ego.<sup>4</sup>

<sup>4</sup> We are very well aware that we have not ex-

## VIII. BEING IN LOVE AND HYPNOSIS

EVEN in its caprices the usage of language remains true to some kind of reality. Thus it gives the name of *love* to a great many kinds of emotional relationship which we too group together theoretically as love; but then again it feels a doubt whether this love is real, true, actual love, and so hints at a whole scale of possibilities within range of the phenomena of love. We shall have no difficulty in making the same discovery empirically.

In one class of cases, being in love is nothing more than object-cathexis on the part of the sexual instincts with a view to directly sexual satisfaction, a cathexis which expires, moreover, when this aim has been reached; this is what is called *common, sensual love*. But, as we know, the libidinal situation rarely remains so simple. It was possible to calculate with certainty upon the revival of the need which had just expired; and this must no doubt have been the first motive for directing a lasting cathexis upon the sexual object and for *loving* it in the passionless intervals as well.

To this must be added another factor derived from the astonishing course of development which is pursued by the erotic life of man. In his first phase, which has usually come to an end by the time he is five years old, a child has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which

---

hausted the nature of identification with these examples taken from pathology, and that we have consequently left part of the riddle of group formations untouched. A far more fundamental and comprehensive psychological analysis would have to intervene at this point. A path leads from identification by way of imitation to empathy, that is, to the comprehension of the mechanism by means of which we are enabled to take up any attitude at all towards another mental life. Moreover there is still much to be explained in the manifestations of existing identifications. These result among other things in a person limiting his aggressiveness towards those with whom he has identified himself, and in his sparing them and giving them help. The study of such identifications, like those, for instance, which lie at the root of clan feeling, led Robertson Smith to the surprising result that they rest upon the recognition of a common substance (*Kinship and Marriage*, 1885), and may even therefore be brought about by a meal eaten in common. This feature makes it possible to connect this kind of identification with the early history of the human family which I constructed in *Totem and Taboo*.

must be described as being "inhibited in their aim [*zielgehemmte*]." The emotions which he feels henceforward towards these objects of his love are characterized as *tender*. It is well known that the earlier *sensual* tendencies remain more or less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.<sup>1</sup>

At puberty, as we know, there set in new and very strong tendencies with directly sexual aims. In unfavourable cases they remain separate, in the form of a sensual current, from the tender emotional trends which persist. We are then faced by a picture the two aspects of which certain movements in literature take such delight in idealizing. A man of this kind will show a sentimental enthusiasm for women whom he deeply respects but who do not excite him to sexual activities, and he will only be potent with other women whom he does not love but thinks little of or even despises.<sup>2</sup> More often, however, the adolescent succeeds in bringing about a certain degree of synthesis between the unsensual, heavenly love and the sensual, earthly love, and his relation to his sexual object is characterized by the interaction of uninhibited instincts and of instincts inhibited in their aim. The depth to which anyone is in love, as contrasted with his purely sensual desire, may be measured by the size of the share taken by the inhibited instincts of tenderness.

In connection with this question of being in love, we have always been struck with the phenomenon of sexual over-estimation—the fact that the loved object enjoys a certain amount of freedom from criticism, and that all its characteristics are valued more highly than those of people who are not loved, or than its own were at a time when it itself was not loved. If the sensual tendencies are somewhat more effectively repressed or set aside, the illusion is produced that the object has come to be sensually loved on account of its spiritual merits, whereas on the contrary these merits may really only have been lent to it by its sensual charm.

The tendency which falsifies judgment in this respect is that of *idealization*. But this makes it easier for us to find our way about. We see that the object is being treated in the same way as our own ego, so that when we are in love a considerable amount of narcissistic li-

bido overflows on to the object. It is even obvious, in many forms of love choice, that the object serves as a substitute for some unattained ego ideal of our own. We love it on account of the perfections which we have striven to reach for our own ego, and which we should now like to procure in this roundabout way as a means of satisfying our narcissism.

If the sexual over-estimation and the being in love increase even further, then the interpretation of the picture becomes still more unmistakable. The tendencies whose trend is towards directly sexual satisfaction may now be pushed back entirely, as regularly happens, for instance, with the young man's sentimental passion; the ego becomes more and more unassuming and modest, and the object more and more sublime and precious, until at last it gets possession of the entire self-love of the ego, whose self-sacrifice thus follows as a natural consequence. The object has, so to speak, consumed the ego. Traits of humility, of the limitation of narcissism, and of self-injury occur in every case of being in love; in the extreme case they are only intensified, and, as a result of the withdrawal of the sensual claims, they remain in solitary supremacy.

This happens especially easily with love that is unhappy and cannot be satisfied; for, in spite of everything, each sexual satisfaction always involves a reduction in sexual over-estimation. Contemporaneously with this *devotion* of the ego to the object, which is no longer to be distinguished from a sublimated devotion to an abstract idea, the functions allotted to the ego ideal entirely cease to operate. The criticism exercised by that faculty is silent; everything that the object does and asks for is right and blameless. Conscience has no application to anything that is done for the sake of the object; in the blindness of love, remorselessness is carried to the pitch of crime. The whole situation can be completely summarized in a formula: *The object has taken the place of the ego ideal.*

It is now easy to define the distinction between identification and such extreme developments of being in love as may be described as *fascination* or *infatuation*. In the former case, the ego has enriched itself with the properties of the object, it has *introjected* the object into itself, as Ferenczi expresses it. In the second case, it is impoverished, it has surrendered itself to the object, it has substituted the object for its most important constituent. Closer consideration soon makes it plain, however, that this

<sup>1</sup> See *Three Contributions to the Theory of Sex*, *op. cit.*

<sup>2</sup> "The Most Prevalent Form of Degradation in Erotic Life," *Collected Papers*, IV.

kind of account creates an illusion of contradistinctions that have no real existence. Economically there is no question of impoverishment or enrichment; it is even possible to describe an extreme case of being in love as a state in which the ego has introjected the object into itself. Another distinction is perhaps better calculated to meet the essence of the matter. In the case of identification, the object has been lost or given up; it is then set up again inside the ego, and the ego makes a partial alteration in itself after the model of the lost object. In the other case, the object is retained, and there is a hyper-cathexis of it by the ego and at the ego's expense. But here again a difficulty presents itself. Is it quite certain that identification presupposes that object-cathexis has been given up? Can there be no identification with the object retained? And before we embark upon a discussion of this delicate question, the perception may already be beginning to dawn on us that yet another alternative embraces the real essence of the matter, namely, *whether the object is put in the place of the ego or of the ego ideal.*

From being in love to hypnosis is evidently only a short step. The respects in which the two agree are obvious. There is the same humble subjection, the same compliance, the same absence of criticism, towards the hypnotist just as towards the loved object. There is the same absorption of one's own initiative; no one can doubt that the hypnotist has stepped into the place of the ego ideal. It is only that everything is even clearer and more intense in hypnosis, so that it would be more to the point to explain being in love by means of hypnosis than the other way round. The hypnotist is the sole object, and no attention is paid to any but him. The fact that the ego experiences in a dream-like way whatever he may request or assert reminds us that we omitted to mention among the functions of the ego ideal the business of testing the reality of things.<sup>1</sup> No wonder that the ego takes a perception for real if its reality is vouched for by the mental faculty which ordinarily discharges the duty of testing the reality of things. The complete absence of tendencies which are uninhibited in their sexual aims contributes further towards the extreme purity of the phenomena. The hypnotic relation is the devotion of someone in love to an unlimited degree but with sexual satisfaction excluded; whereas in the case of being in love

this kind of satisfaction is only temporarily kept back, and remains in the background as a possible aim at some later time.

But, on the other hand, we may also say that the hypnotic relation is (if the expression is permissible) a group formation with two members. Hypnosis is not a good object for comparison with a group formation, because it is truer to say that it is identical with it. Out of the complicated fabric of the group it isolates one element for us—the behaviour of the individual to the leader. Hypnosis is distinguished from a group formation by this limitation of number, just as it is distinguished from being in love by the absence of directly sexual tendencies. In this respect it occupies a middle position between the two.

It is interesting to see that it is precisely those sexual tendencies that are inhibited in their aims which achieve such lasting ties between men. But this can easily be understood from the fact that they are not capable of complete satisfaction, while sexual tendencies which are uninhibited in their aims suffer an extraordinary reduction through the discharge of energy every time the sexual aim is attained. It is the fate of sensual love to become extinguished when it is satisfied; for it to be able to last, it must from the first be mixed with purely tender components—with such, that is, as are inhibited in their aims—or it must itself undergo a transformation of this kind.

Hypnosis would solve the riddle of the libidinal constitution of groups for us straight away, if it were not that it itself exhibits some features which are not met by the rational explanation we have hitherto given of it as a state of being in love, with the directly sexual tendencies excluded. There is still a great deal in it which we must recognize as unexplained and mystical. It contains an additional element of paralysis derived from the relation between someone with superior power and someone who is without power and helpless—which may afford a transition to the hypnosis of terror which occurs in animals. The manner in which it is produced and its relationship to sleep are not clear; and the puzzling way in which some people are subject to it, while others resist it completely, points to some factor still unknown which is realized in it and which perhaps alone makes possible the purity of the attitudes of the libido which it exhibits. It is noticeable that, even when there is complete suggestive compliance in other respects, the moral conscience of the person hypnotized may show

<sup>1</sup> See "Metapsychological Supplement to the Theory of Dreams," *Collected Papers*, IV.

resistance. But this may be due to the fact that in hypnosis as it is usually practised some knowledge may be retained that what is happening is only a game, an untrue reproduction of another situation of far more importance to life.

But after the preceding discussions we are quite in a position to give the formula for the libidinal constitution of groups: or at least of such groups as we have hitherto considered, namely, those that have a leader and have not been able by means of too much *organization* to acquire secondarily the characteristics of an individual. *A primary group of this kind is a number of individuals who have substituted one and the same object for their ego ideal and have consequently identified themselves with one another in their ego.* This condition admits of graphic representation:

## IX. THE HERD INSTINCT

We cannot for long enjoy the illusion that we have solved the riddle of the group with this formula. It is impossible to escape the immediate and disturbing recollection that all we have really done has been to shift the question on to the riddle of hypnosis, about which so many points have yet to be cleared up. And now another objection shows us our further path.

It might be said that the intense emotional ties which we observe in groups are quite sufficient to explain one of their characteristics—the lack of independence and initiative in their members, the similarity in the reactions of all of them, their reduction, so to speak, to the level of group individuals. But if we look at it as a whole, a group shows us more than this. Some of its features—the weakness of intellectual ability, the lack of emotional restraint, the incapacity for moderation and delay, the inclination to exceed every limit in the expression of emotion and to work it off completely in the form of action—these and similar features, which we find so impressively described in Le Bon, show an unmistakable picture of a regression of mental activity to an earlier stage such as we are not surprised to find among savages

or children. A regression of this sort is in particular an essential characteristic of common groups, while, as we have heard, in organized and artificial groups it can to a large extent be checked.

We thus have an impression of a state in which an individual's separate emotion and personal intellectual act are too weak to come to anything by themselves and are absolutely obliged to wait till they are reinforced through being repeated in a similar way in the other members of the group. We are reminded of how many of these phenomena of dependence are part of the normal constitution of human society, of how little originality and personal courage are to be found in it, of how much every individual is ruled by those attitudes of the group mind which exhibit themselves in such forms as racial characteristics, class prejudices, public opinion, etc. The influence of suggestion becomes a greater riddle for us when we admit that it is not exercised only by the leader, but by every individual upon every other individual; and we must reproach ourselves with having unfairly emphasized the relation to the leader and with having kept the other factor of mutual suggestion too much in the background.

After this encouragement to modesty, we shall be inclined to listen to another voice, which promises us an explanation based upon simpler grounds. Such a one is to be found in Trotter's thoughtful book upon the herd instinct, concerning which my only regret is that it does not entirely escape the antipathies that were set loose by the recent Great War.<sup>1</sup>

Trotter derives the mental phenomena that are described as occurring in groups from a herd instinct (gregariousness), which is innate in human beings just as in other species of animals. Biologically this gregariousness is an analogy to multicellularity and as it were a continuation of it. From the standpoint of the libido theory, it is a further manifestation of the inclination, which proceeds from the libido, and which is felt by all living beings of the same kind, to combine in more and more comprehensive units.<sup>2</sup> The individual feels *incomplete* if he is alone. The dread shown by small children would seem already to be an expression of this herd instinct. Opposition to the herd is as good as separation from it, and is therefore anxiously avoided. But the herd turns

<sup>1</sup> W. Trotter: *Instincts of the Herd in Peace and War* Fisher Unwin, 1916.

<sup>2</sup> See *Beyond the Pleasure Principle*, p. 639 above.

away from anything that is new or unusual. The herd instinct would appear to be something primary, something *which cannot be split up*.

Trotter gives as the list of instincts which he considers as primary those of self-preservation, of nutrition, of sex, and of the herd. The last often comes into opposition with the others. The feelings of guilt and of duty are the peculiar possessions of a gregarious animal. Trotter also derives from the herd instinct the repressive forces which psycho-analysis has shown to exist in the ego, and from the same sources accordingly the resistances which the physician comes up against in psycho-analytic treatment. Speech owes its importance to its aptitude for mutual understanding in the herd, and upon it the identification of the individuals with one another largely rests.

While Le Bon is principally concerned with typical transient group formations, and McDougall with stable associations, Trotter has chosen as the centre of his interest the most generalized form of assemblage in which man, that ζῷον πολιτικόν,<sup>1</sup> passed his life, and he gives us its psychological basis. But Trotter is under no necessity of tracing back the herd instinct, for he characterizes it as primary and not further reducible. Boris Sidis's attempt, to which he refers, at tracing the herd instinct back to suggestibility is fortunately superfluous as far as he is concerned; it is an explanation of a familiar and unsatisfactory type, and the converse proposition—that suggestibility is a derivative of the herd instinct—would seem to me to throw far more light on the subject.

But Trotter's exposition, with even more justice than the other's, is open to the objection that it takes too little account of the leader's part in a group, while we incline rather to the opposite judgment, that it is impossible to grasp the nature of a group if the leader is disregarded. The herd instinct leaves no room at all for the leader; he is merely thrown in along with the herd, almost by chance; it follows, too, that no path leads from this instinct to the need for a God; the herd is without a herdsman. But besides this Trotter's exposition can be undermined psychologically; that is to say, it can be made at all events probable that the herd instinct is not irreducible, that it is not primary in the same sense as the instinct of self-preservation and the sexual instinct.

It is naturally no easy matter to trace the ontogenesis of the herd instinct. The dread

which is shown by small children when they are left alone, and which Trotter claims as being already a manifestation of the instinct, nevertheless suggests more readily another interpretation. The dread relates to the child's mother, and later to other familiar persons, and it is the expression of an unfulfilled desire, which the child does not yet know how to deal with in any way except by turning it into dread.<sup>2</sup> Nor is the child's dread when it is alone pacified by the sight of any haphazard *member of the herd*, but on the contrary it is only brought into existence by the approach of a *stranger* of this sort. Then for a long time nothing in the nature of herd instinct or group feeling is to be observed in children. Something like it grows up first of all, in a nursery containing many children, out of the children's relation to their parents, and it does so as a reaction to the initial envy with which the elder child receives the younger one. The elder child would certainly like to put its successor jealously aside, to keep it away from the parents, and to rob it of all its privileges; but in face of the fact that this child (like all that come later) is loved by the parents in just the same way, and in consequence of the impossibility of maintaining its hostile attitude without damaging itself, it is forced into identifying itself with the other children. So there grows up in the troop of children a communal or group feeling, which is then further developed at school. The first demand made by this reaction-formation is for justice, for equal treatment for all. We all know how loudly and implacably this claim is put forward at school. If one cannot be the favourite oneself, at all events nobody else shall be the favourite. This transformation—the replacing of jealousy by a group feeling in the nursery and classroom—might be considered improbable, if the same process could not later on be observed again in other circumstances. We have only to think of the troop of women and girls, all of them in love in an enthusiastically sentimental way, who crowd round a singer or pianist after his performance. It would certainly be easy for each of them to be jealous of the rest; but, in face of their numbers and the consequent impossibility of their reaching the aim of their love, they renounce it, and, instead of pulling out one another's hair, they act as a united group, do homage to the hero of the occasion with their common actions, and would probably

<sup>2</sup> See the remarks upon Dread in *General Introduction to Psycho-Analysis*, Lecture XXV, p. 607 above.

<sup>1</sup> Political animal.—Ed.

be glad to have a share of his flowing locks. Originally rivals, they have succeeded in identifying themselves with one another by means of a similar love for the same object. When, as is usual, a situation in the field of the instincts is capable of various outcomes, we need not be surprised if the actual outcome is one which involves the possibility of a certain amount of satisfaction, while another, even though in itself more obvious, is passed over because the circumstances of life prevent its attaining this aim.

What appears later on in society in the shape of *Gemeingeist*, *esprit de corps*, group spirit, etc., does not belie its derivation from what was originally envy. No one must want to put himself forward, every one must be the same and have the same. Social justice means that we deny ourselves many things so that others may have to do without them as well, or, what is the same thing, may not be able to ask for them. This demand for equality is the root of social conscience and the sense of duty. It reveals itself unexpectedly in the syphilitic's dread of infecting other people, which psychoanalysis has taught us to understand. The dread exhibited by these poor wretches corresponds to their violent struggles against the unconscious wish to spread their infection on to other people; for why should they alone be infected and cut off from so much? Why not other people as well? And the same germ is to be found in the pretty anecdote of the judgment of Solomon. If one woman's child is dead, the other shall not have a live one either. The bereaved woman is recognized by this wish.

Thus social feeling is based upon the reversal of what was first a hostile feeling into a positively-toned tie of the nature of an identification. So far as we have hitherto been able to follow the course of events, this reversal appears to be effected under the influence of a common tender tie with a person outside the group. We do not ourselves regard our analysis of identification as exhaustive, but it is enough for our present purpose that we should revert to this one feature—its demand that equalization shall be consistently carried through. We have already heard in the discussion of the two artificial groups, church and army, that their preliminary condition is that all their members should be loved in the same way by one person, the leader. Do not let us forget, however, that the demand for equality in a group applies only to its members and not to the leader. All the members must be equal to one another, but they

all want to be ruled by one person. Many equals, who can identify themselves with one another, and a single person superior to them all—that is the situation that we find realized in groups which are capable of subsisting. Let us venture, then, to correct Trotter's pronouncement that man is a herd animal and assert that he is rather a horde animal, an individual creature in a horde led by a chief.

#### X. THE GROUP AND THE PRIMAL HORDE

IN 1912 I took up a conjecture of Darwin's to the effect that the primitive form of human society was that of a horde ruled over despotically by a powerful male. I attempted to show that the fortunes of this horde have left indelible traces upon the history of human descent; and, especially, that the development of totemism, which comprises in itself the beginnings of religion, morality, and social organization, is connected with the killing of the chief by violence and the transformation of the paternal horde into a community of brothers.<sup>1</sup> To be sure, this is only a hypothesis, like so many others with which archaeologists endeavour to lighten the darkness of prehistoric times—a "Just-So Story," as it was amusingly called by a not unkind critic (Kroeger); but I think it is creditable to such a hypothesis if it proves able to bring coherence and understanding into more and more new regions.

Human groups exhibit once again the familiar picture of an individual of superior strength among a troop of similar companions, a picture which is also contained in our idea of the primal horde. The psychology of such a group, as we know it from the descriptions to which we have so often referred—the dwindling of the conscious individual personality, the focusing of thoughts and feelings into a common direction, the predominance of the emotions and of the unconscious mental life, the tendency to the immediate carrying out of intentions as they emerge—all this corresponds to a state of regression to a primitive mental activity, of just such a sort as we should be inclined to ascribe to the primal horde.<sup>2</sup>

<sup>1</sup> *Totem and Taboo*.

<sup>2</sup> What we have just described in our general characterization of mankind must apply especially to the primal horde. The will of the individual was too weak; he did not venture upon action. No impulses whatever came into play except collective ones; there was only a common will, there were no single ones. An idea did not dare to turn itself into a volition unless it felt itself reinforced by a perception of its general diffusion. This weakness of the idea is to be explained by the strength of the emotional tie which

Thus the group appears to us as a revival of the primal horde. Just as primitive man virtually survives in every individual, so the primal horde may arise once more out of any random crowd; in so far as men are habitually under the sway of group formation, we recognize in it the survival of the primal horde. We must conclude that the psychology of the group is the oldest human psychology; what we have isolated as individual psychology, by neglecting all traces of the group, has only since come into prominence out of the old group psychology, by a gradual process which may still, perhaps, be described as incomplete. We shall later venture upon an attempt at specifying the point of departure of this development.

Further reflection will show us in what respect this statement requires correction. Individual psychology must, on the contrary, be just as old as group psychology, for from the first there were two kinds of psychologies, that of the individual members of the group and that of the father, chief, or leader. The members of the group were subject to ties just as we see them today, but the father of the primal horde was free. His intellectual acts were strong and independent even in isolation, and his will needed no reinforcement from others. Consistency leads us to assume that his ego had few libidinal ties; he loved no one but himself, or other people only in so far as they served his needs. To objects his ego gave away no more than was barely necessary.

He, at the very beginning of the history of mankind, was the *Superman* whom Nietzsche only expected from the future. Even today the members of a group stand in need of the illusion that they are equally and justly loved by their leader; but the leader himself need love no one else, he may be of a masterly nature, absolutely narcissistic, but self-confident and independent. We know that love puts a check upon narcissism, and it would be possible to show how, by operating in this way, it became a factor of civilization.

The primal father of the horde was not yet immortal, as he later became by deification. If

is shared by all members of the horde; but the similarity in the circumstances of their life and the absence of any private property assist in determining the uniformity of their individual mental acts. As we may observe with children and soldiers, common activity is not excluded even in the excremental functions. The one great exception is provided by the sexual act, in which a third person is at best superfluous and in the extreme case is condemned to a state of painful expectancy. As to the reaction of the sexual need (for genital gratification) towards gregariousness, see below.

he died, he had to be replaced; his place was probably taken by a youngest son, who had up to then been a member of the group like any other. There must therefore be a possibility of transforming group psychology into individual psychology; a condition must be discovered under which such a transformation is easily accomplished, just as it is possible for bees in case of necessity to turn a larva into a queen instead of into a worker. One can imagine only one possibility: the primal father had prevented his sons from satisfying their directly sexual tendencies; he forced them into abstinence and consequently into the emotional ties with him and with one another which could arise out of those of their tendencies that were inhibited in their sexual aim. He forced them, so to speak, into group psychology. His sexual jealousy and intolerance became, in the last resort, the causes of group psychology.<sup>1</sup>

Whoever became his successor was also given the possibility of sexual satisfaction, and was by that means offered a way out of the conditions of group psychology. The fixation of the libido to woman and the possibility of satisfaction without any need for delay or accumulation made an end of the importance of those of his sexual tendencies that were inhibited in their aim, and allowed his narcissism always to rise to its full height. We shall return in a postscript to this connection between love and character formation.

We may further emphasize, as being specially instructive, the relation that holds between the contrivance by means of which an artificial group is held together and the constitution of the primal horde. We have seen that with an army and a church this contrivance is the illusion that the leader loves all of the individuals equally and justly. But this is simply an idealistic remodelling of the state of affairs in the primal horde, where all of the sons knew that they were equally persecuted by the primal father, and feared him equally. This same recasting upon which all social duties are built up is already presupposed by the next form of human society, the totemistic clan. The indestructible strength of the family as a natural group formation rests upon the fact that this necessary presupposition of the father's equal love can have a real application in the family.

But we expect even more of this derivation

<sup>1</sup> It may perhaps also be assumed that the sons, when they were driven out and separated from their father, advanced from identification with one another to homosexual object love, and in this way won freedom to kill their father.

of the group from the primal horde. It ought also to help us to understand what is still incomprehensible and mysterious in group formations—all that lies hidden behind the enigmatic words *hypnosis* and *suggestion*. And I think it can succeed in this too. Let us recall that hypnosis has something positively uncanny about it; but the characteristic of uncanniness suggests something old and familiar that has undergone repression.<sup>1</sup> Let us consider how hypnosis is induced. The hypnotist asserts that he is in possession of a mysterious power which robs the subject of his own will, or, which is the same thing, the subject believes it of him. This mysterious power (which is even now often described popularly as animal magnetism) must be the same that is looked upon by primitive people as the source of taboo, the same that emanates from kings and chieftains and makes it dangerous to approach them (*mana*). The hypnotist, then, is supposed to be in possession of this power; and how does he manifest it? By telling the subject to look him in the eyes; his most typical method of hypnotizing is by his look. But it is precisely the sight of the chieftain that is dangerous and unbearable for primitive people, just as later that of the Godhead is for mortals. Even Moses had to act as an intermediary between his people and Jehovah, since the people could not support the sight of God; and when he returned from the presence of God his face shone—some of the *mana* had been transferred on to him, just as happens with the intermediary among primitive people.<sup>2</sup>

It is true that hypnosis can also be evoked in other ways, for instance by fixing the eyes upon a bright object or listening to a monotonous sound. This is misleading and has given occasion to inadequate physiological theories. As a matter of fact, these procedures merely serve to divert conscious attention and to hold it riveted. The situation is the same as if the hypnotist had said to the subject: "Now concern yourself exclusively with my person; the rest of the world is quite uninteresting." It would of course be technically inexpedient for a hypnotist to make such a speech; it would tear the subject away from his unconscious attitude and stimulate him to conscious opposition. The hypnotist avoids directing the subject's conscious thoughts towards his own intentions, and makes the person upon whom he is experimenting sink into an activity in which

the world is bound to seem uninteresting to him; but at the same time the subject is in reality unconsciously concentrating his whole attention upon the hypnotist, and is getting into an attitude of *rapport*, of transference on to him. Thus the indirect methods of hypnotizing, like many of the technical procedures used in making jokes, have the effect of checking certain distributions of mental energy which would interfere with the course of events in the unconscious, and they lead eventually to the same result as the direct methods of influence by means of staring or stroking.<sup>3</sup>

Ferenczi has made the true discovery that when a hypnotist gives the command to sleep, which is often done at the beginning of hypnosis, he is putting himself in the place of the subject's parents. He thinks that two sorts of hypnosis are to be distinguished: one coaxing and soothing, which he considers is modelled upon the mother, and another threatening, which is derived from the father.<sup>4</sup> Now the command to sleep in hypnosis means nothing more nor less than an order to withdraw all interest from the world and to concentrate it upon the person of the hypnotist. And it is so understood by the subject; for in this withdrawal of interest from the outer world lies the psychological characteristic of sleep, and the kinship between sleep and the state of hypnosis is based upon it.

By the measures that he takes, then, the hypnotist awakens in the subject a portion of his archaic inheritance which had also made him compliant towards his parents and which had experienced an individual re-animation in his relation to his father; what is thus awakened is the idea of a paramount and dangerous personality, towards whom only a passive-

<sup>3</sup> This situation, in which the subject's attitude is unconsciously directed towards the hypnotist, while he is consciously occupied with monotonous and uninteresting perceptions, finds a parallel among the events of psycho-analytic treatment, which deserves to be mentioned here. At least once in the course of every analysis, a moment comes when the patient obstinately maintains that just now positively nothing whatever occurs to his mind. His free associations come to a stop and the usual incentives for putting them in motion fail in their effect. As a result of pressure, the patient is at last induced to admit that he is thinking of the view from the consulting-room window, of the wall-paper that he sees before him, or of the gas-lamp hanging from the ceiling. Then one knows at once that he has gone off into the transference and that he is engaged upon what are still unconscious thoughts relating to the physician; and one sees the stoppage in the patient's associations disappear, as soon as he has been given this explanation.

<sup>2</sup> See *Totem and Taboo* and the sources there quoted.

masochistic attitude is possible, to whom one's will has to be surrendered—while to be alone with him, "to look him in the face," appears a hazardous enterprise. It is only in some such way as this that we can picture the relation of the individual member of the primal horde to the primal father. As we know from other reactions, individuals have preserved a variable degree of personal aptitude for reviving old situations of this kind. Some knowledge that, in spite of everything, hypnosis is only a game, a deceptive renewal of these old impressions, may however remain behind and take care that there is a resistance against any too serious consequences of the suspension of the will in hypnosis.

The uncanny and coercive characteristics of group formations, which are shown in their suggestion phenomena, may therefore with justice be traced back to the fact of their origin from the primal horde. The leader of the group is still the dreaded primal father; the group still wishes to be governed by unrestricted force; it has an extreme passion for authority; in Le Bon's phrase, it has a thirst for obedience. The primal father is the group ideal, which governs the ego in the place of the ego ideal. Hypnosis has a good claim to being described as a group of two; there remains as a definition for suggestion: a conviction which is not based upon perception and reasoning but upon an erotic tie.<sup>1</sup>

#### XI. A DIFFERENTIATING GRADE IN THE EGO

If we survey the life of an individual man of today, bearing in mind the mutually complementary accounts of group psychology given by the authorities, we may lose the courage, in face of the complications that are revealed, to attempt a comprehensive exposition. Each individual is a component part of numerous groups, he is bound by ties of identification in many directions, and he has built up his ego ideal upon the most various models. Each individual, therefore, has a share in numerous group minds—those of his race, of his class, of his creed, of his nationality, etc.—and he can

also raise himself above them to the extent of having a scrap of independence and originality. Such stable and lasting group formations, with their uniform and constant effects, are less striking to an observer than the rapidly formed and transient groups from which Le Bon has made his brilliant psychological character sketch of the group mind. And it is just in these noisy ephemeral groups, which are as it were superimposed upon the others, that we are met by the prodigy of the complete, even though only temporary, disappearance of exactly what we have recognized as individual acquirements.

We have interpreted this prodigy as meaning that the individual gives up his ego ideal and substitutes for it the group ideal as embodied in the leader. And we must add, by way of correction, that the prodigy is not equally great in every case. In many individuals the separation between the ego and the ego ideal is not very far advanced; the two still coincide readily; the ego has often preserved its earlier self-complacency. The selection of the leader is very much facilitated by this circumstance. He need only possess the typical qualities of the individuals concerned in a particularly clearly marked and pure form, and need only give an impression of greater force and of more freedom of libido; and in that case the need for a strong chief will often meet him half-way and invest him with a predominance to which he would otherwise perhaps have had no claim. The other members of the group, whose ego ideal would not, apart from this, have become embodied in his person without some correction, are then carried away with the rest by *suggestion*, that is to say, by means of identification.

We are aware that what we have been able to contribute towards the explanation of the libidinal structure of groups leads back to the distinction between the ego and the ego ideal and to the double kind of tie which this makes possible—identification, and substitution of the object for the ego ideal. The assumption of this kind of differentiating grade (*Stufe*) in the ego as a first step in an analysis of the ego must gradually establish its justification in the most various regions of psychology. In my paper, "Narcissism: an Introduction," I have put together all the pathological material that could at the moment be used in support of this separation. But it may be expected that when we penetrate deeper into the psychology of the psychoses its significance will be discovered to be far greater. Let us reflect that the ego now

<sup>1</sup> It seems to me worth emphasizing the fact that the discussions in this section have induced us to give up Bernheim's conception of hypnosis and go back to the *naïf* earlier one. According to Bernheim, all hypnotic phenomena are to be traced to the factor of suggestion, which is not itself capable of further explanation. We have come to the conclusion that suggestion is a partial manifestation of the state of hypnosis, and that hypnosis is solidly founded upon a predisposition which has survived in the unconscious from the early history of the human family.

appears in the relation of an object to the ego ideal which has been developed out of it, and that all the interplay between an outer object and the ego as a whole, with which our study of the neuroses has made us acquainted, may possibly be repeated upon this new scene of action inside the ego.

In this place I shall only follow up one of the consequences which seem possible from this point of view, thus resuming the discussion of a problem which I was obliged to leave unsolved elsewhere.<sup>1</sup> Each of the mental differentiations that we have become acquainted with represents a fresh aggravation of the difficulties of mental functioning, increases its instability, and may become the starting-point for its breakdown, that is, for the onset of a disease. Thus, by being born we have made the step from an absolutely self-sufficient narcissism to the perception of a changing outer world and to the beginnings of the discovery of objects. And with this is associated the fact that we cannot endure the new state of things for long, that we periodically revert from it, in our sleep, to our former condition of absence of stimulation and avoidance of objects. It is true, however, that in this we are following a hint from the outer world, which, by means of the periodical change of day and night, temporarily withdraws the greater part of the stimuli that affect us. The second example, which is pathologically more important, is not subject to any such qualification. In the course of our development we have effected a separation of our mental existence into a coherent ego and into an unconscious and repressed portion which is left outside it; and we know that the stability of this new acquisition is exposed to constant shocks. In dreams and in neuroses what is thus excluded knocks for admission at the gates, guarded though they are by resistances; and in our waking health we make use of special artifices for allowing what is repressed to circumvent the resistances and for receiving it temporarily into our ego to the increase of our pleasure. Wit and humour, and to some extent the comic in general, may be regarded in this light. Everyone acquainted with the psychology of the neuroses will think of similar examples of less importance; but I hasten on to the application I have in view.

It is quite conceivable that the separation of the ego ideal from the ego cannot be borne for long either, and has to be temporarily undone. In all renunciations and limitations imposed

upon the ego, a periodical infringement of the prohibition is the rule; this indeed is shown by the institution of festivals, which in origin are nothing more nor less than excesses provided by law and which owe their cheerful character to the release which they bring.<sup>2</sup> The Saturnalia of the Romans and our modern carnival agree in this essential feature with the festivals of primitive people, which usually end in debaucheries of every kind and the transgression of what are at other times the most sacred commandments. But the ego ideal comprises the sum of all the limitations in which the ego has to acquiesce, and for that reason the abrogation of the ideal would necessarily be a magnificent festival for the ego, which might then once again feel satisfied with itself.<sup>3</sup>

There is always a feeling of triumph when something in the ego coincides with the ego ideal. And the sense of guilt (as well as the sense of inferiority) can also be understood as an expression of tension between the ego and the ego ideal.

It is well known that there are people the general colour of whose mood oscillates periodically from an excessive depression through some kind of intermediate state to an exalted sense of well-being. These oscillations appear in very different degrees of amplitude, from what is just noticeable to those extreme instances which, in the shape of melancholia and mania, make the most painful or disturbing inroads upon the life of the person concerned. In typical cases of this cyclical depression, outer exciting causes do not seem to play any decisive part; as regards inner motives, nothing more (or nothing different) is to be found in these patients than in all others. It has consequently become the custom to consider these cases as not being psychogenic. We shall refer later on to those other exactly similar cases of cyclical depression which can nevertheless easily be traced back to mental traumata.

Thus the foundation of these spontaneous oscillations of mood is unknown; we are without insight into the mechanism of the displacement of a melancholia by a mania. So we are free to suppose that these patients are people in whom our conjecture might find an actual application—their ego ideal might be tempo-

<sup>2</sup> *Totem and Taboo*.

<sup>3</sup> Trotter traces repression back to the herd instinct. It is a translation of this into another form of expression rather than a contradiction when I say in my "On Narcissism: an Introduction" that, on the part of the ego, the construction of an ideal is the condition of repression [see p. 408 above].

<sup>1</sup> "Mourning and Melancholia."

rarily resolved into their ego after having previously ruled it with especial strictness.

Let us keep to what is clear: On the basis of our analysis of the ego it cannot be doubted that in cases of mania the ego and the ego ideal have fused together, so that the person, in a mood of triumph and self-satisfaction, disturbed by no self-criticism, can enjoy the abolition of his inhibitions, his feelings of consideration for others, and his self-reproaches. It is not so obvious, but nevertheless very probable, that the misery of the melancholiac is the expression of a sharp conflict between the two faculties of his ego, a conflict in which the ideal, in an excess of sensitiveness, relentlessly exhibits its condemnation of the ego in delusions of inferiority and in self-depreciation. The only question is whether we are to look for the causes of these altered relations between the ego and the ego ideal in the periodic rebellions, which we have postulated above, against the new institution, or whether we are to make other circumstances responsible for them.

A change into mania is not an indispensable feature of the symptomatology of melancholic depression. There are simple melancholias, some in single and some in recurring attacks, which never show this development. On the other hand, there are melancholias in which the exciting cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as a result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytical investigation.<sup>1</sup> So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.<sup>2</sup>

<sup>1</sup> Cf. Abraham: "Ansätze zur psychoanalytischen Erforschung und Behandlung des manisch-depressiven Irreseins," 1912, in *Klinische Beiträge zur Psychoanalyse*, 1921.

<sup>2</sup> To speak more accurately, they conceal themselves behind the reproaches directed towards the person's own ego, and lend them the fixity, tenacity, and imperativeness which characterize the self-reproaches of a melancholiac.

A melancholia of this kind may also end in a change to mania; so that the possibility of this happening represents a feature which is independent of the other characteristics in the symptomatology.

Nevertheless I see no difficulty in assigning to the factor of the periodical rebellion of the ego against the ego ideal a share in both kinds of melancholia, the psychogenic as well as the spontaneous. In the spontaneous kind, it may be supposed that the ego ideal is inclined to display a peculiar strictness, which then results automatically in its temporary suspension. In the psychogenic kind, the ego would be incited to rebellion by ill-treatment on the part of its ideal—an ill treatment which it encounters when there has been identification with a rejected object.

## XII. POSTSCRIPT

IN the course of the enquiry which has just been brought to a provisional end we came across a number of side-paths which we avoided pursuing in the first instance but in which there was much that offered us promises of insight. We propose now to take up a few of the points that have been left on one side in this way.

A. The distinction between identification of the ego with an object and replacement of the ego ideal by an object finds an interesting illustration in the two great artificial groups which we began by studying, the army and the Christian church.

It is obvious that a soldier takes his superior, that is, really, the leader of the army, as his ideal, while he identifies himself with his equals, and derives from this community of their egos the obligations for giving mutual help and for sharing possessions which comradeship implies. But he becomes ridiculous if he tries to identify himself with the general. The soldier in *Wallensteins Lager* laughs at the sergeant for this very reason:

*Wie er räuspert und wie er spuckt.*

*Das habt ihr ihm glücklich abgeguckt!*<sup>3</sup>

It is otherwise in the Catholic Church. Every Christian loves Christ as his ideal and feels himself united with all other Christians by the tie of identification. But the Church requires more of him. He has also to identify himself with Christ and love all other Christians as Christ loved them. At both points, therefore, the Church requires that the position of the libido which is given by a group formation should be supplemented. Identification has to

<sup>3</sup> How he clears his throat and how he spits, that you have cleverly copied from him.—TR.

be added where object-choice has taken place, and object love where there is identification. This addition evidently goes beyond the constitution of the group. One can be a good Christian and yet be far from the idea of putting oneself in Christ's place and of having like him an all-embracing love for mankind. One need not think oneself capable, weak mortal that one is, of the Saviour's largeness of soul and strength of love. But this further development in the distribution of libido in the group is probably the factor upon which Christianity bases its claim to have reached a higher ethical level.

B. We have said that it would be possible to specify the point in the mental development of man at which the advance from group to individual psychology was also achieved by the individual members of the group.<sup>1</sup>

For this purpose we must return for a moment to the scientific myth of the father of the primal horde. He was later on exalted into the creator of the world, and with justice, for he had produced all the sons who composed the first group. He was the ideal of each one of them, at once feared and honoured, a fact which led later to the idea of taboo. These many individuals banded themselves together, killed him and cut him in pieces. None of the group of victors could take his place, or, if one of them did, the battles began afresh, until they understood that they must all renounce their father's heritage. They then formed the totemistic community of brothers, all with equal rights and united by the totem prohibitions which were to preserve and to expiate the memory of the murder. But the dissatisfaction with what had been achieved still remained, and it became the source of new developments. The persons who were united in this group of brothers gradually came towards a revival of the old state of things at a new level. Man became once more the chief of a family, and broke down the prerogatives of the gynaeocracy which had become established during the fatherless period. As a compensation for this, he may at that time have acknowledged the mother deities, whose priests were castrated for the mother's protection, after the example that had been given by the father of the primal horde. And yet the new family was only a shadow of the old one; there were numbers of fathers and each one was limited by the rights of the others.

<sup>1</sup> What follows at this point was written under the influence of an exchange of ideas with Otto Rank.

It was then, perhaps, that some individual, in the exigency of his longing, may have been moved to free himself from the group and take over the father's part. He who did this was the first epic poet; and the advance was achieved in his imagination. This poet disguised the truth with lies in accordance with his longing. He invented the heroic myth. The hero was a man who by himself had slain the father—the father who still appeared in the myth as a totemistic monster. Just as the father had been the boy's first ideal, so in the hero who aspires to the father's place the poet now created the first ego ideal. The transition to the hero was probably afforded by the youngest son, the mother's favourite, whom she had protected from paternal jealousy, and who, in the era of the primal horde, had been the father's successor. In the lying poetic fancies of prehistoric times the woman, who had been the prize of battle and the allurements to murder, was probably turned into the seducer and instigator to the crime.

The hero claims to have acted alone in accomplishing the deed, which certainly only the horde as a whole would have ventured upon. But, as Rank has observed, fairy tales have preserved clear traces of the facts which were disavowed. For we often find in them that the hero who has to carry out some difficult task (usually a youngest son, and not infrequently one who has represented himself to the father surrogate as being stupid, that is to say, harmless)—we often find, then, that this hero can carry out his task only by the help of a crowd of small animals, such as bees or ants. These would be the brothers in the primal horde, just as in the same way in dream symbolism insects or vermin signify brothers and sisters (contemptuously, considered as babies). Moreover, every one of the tasks in myths and fairy tales is easily recognizable as a substitute for the heroic deed.

The myth, then, is the step by which the individual emerges from group psychology. The first myth was certainly the psychological, the hero myth, the explanatory nature myth must have followed much later. The poet who had taken this step and had in this way set himself free from the group in his imagination, is nevertheless able (as Rank has further observed) to find his way back to it in reality. For he goes and relates to the group his hero's deeds which he has invented. At bottom this hero is no one but himself. Thus he lowers himself to the level of reality, and raises his hearers to the level of

imagination. But his hearers understand the poet, and, in virtue of their having the same relation of longing towards the primal father, they can identify themselves with the hero.<sup>1</sup>

The lie of the heroic myth culminates in the deification of the hero. Perhaps the deified hero may have been earlier than the Father God and may have been a precursor to the return of the primal father as a deity. The series of gods, then, would run chronologically: Mother Goddess—Hero—Father God. But it is only with the elevation of the never forgotten primal father that the deity acquires the features that we still recognize in him today.<sup>2</sup>

C. A great deal has been said in this paper about directly sexual instincts and those that are inhibited in their aims, and it may be hoped that this distinction will not meet with too much resistance. But a detailed discussion of the question will not be out of place, even if it only repeats what has to a great extent already been said before.

The development of the libido in children has made us acquainted with the first but also the best example of sexual instincts which are inhibited in their aims. All the feelings which a child has towards its parents and those who look after it pass by an easy transition into the wishes which give expression to the child's sexual tendencies. The child claims from these objects of its love all the signs of affection which it knows of; it wants to kiss them, touch them, and look at them; it is curious to see their genitals, and to be with them when they perform their intimate excremental functions; it promises to marry its mother or nurse—whatever it may understand by that; it proposes to itself to bear its father a child, etc. Direct observation, as well as the subsequent analytic investigation of the residue of childhood, leave no doubt as to the complete fusion of tender and jealous feelings and of sexual intentions, and show us in what a fundamental way the child makes the person it loves into the object of all its incompletely centred sexual tendencies.<sup>3</sup>

This first configuration of the child's love,

<sup>1</sup> Cf. Hanns Sachs: "Gemeinsame Tagträume," a summary made by the lecturer himself of a paper read at the Sixth Psycho-analytical Congress, held at the Hague in 1920. *Internationale Zeitschrift für Psychoanalyse*, 1920, Vol. VI. ("Day-Dreams in Common," *International Journal of Psycho-Analysis*, 1920, Vol. I.)

<sup>2</sup> In this brief exposition, I have made no attempt to bring forward any of the material existing in legends, myths, fairy tales, the history of manners, etc., in support of the construction.

<sup>3</sup> See *Three Contributions to the Theory of Sex*.

which in typical cases is co-ordinated with the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards, to a wave of repression. Such of it as is left over shows itself as a purely tender emotional tie, which relates to the same people, but is no longer to be described as *sexual*. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across a tender feeling it is the successor to a completely sensual object tie with the person in question or rather with that person's prototype (or *imago*). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression, or whether it has already been exhausted. To put it still more precisely: it is quite certain that it is still there as a form and possibility, and can always be charged with cathectic energy and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error—the Scylla of under-estimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

A psychology which will not or cannot penetrate the depths of what is repressed regards tender emotional ties as being invariably the expression of tendencies which have no sexual aim, even though they are derived from tendencies which have such an aim.<sup>4</sup>

We are justified in saying that they have been diverted from these sexual aims, even though there is some difficulty in giving a representation of such a diversion of aim which will conform to the requirements of metapsychology. Moreover, those instincts which are inhibited in their aims always preserve some few of their original sexual aims; even an affectionate devotee, even a friend or an admirer, desires the physical proximity and the sight of the person who is now loved only in the "Pauline" sense. If we choose, we may recognize in this diversion of aim a beginning of the *sublimation* of the sexual instincts, or,

<sup>4</sup> Hostile feelings, which are a little more complicated in their construction, offer no exception to this rule.

on the other hand, we may fix the limits of sublimation at some more distant point. Those sexual instincts which are inhibited in their aims have a great functional advantage over those which are uninhibited. Since they are not capable of really complete satisfaction, they are especially adapted to create permanent ties; while those instincts which are directly sexual incur a loss of energy each time they are satisfied, and must wait to be renewed by a fresh accumulation of sexual libido, so that meanwhile the object may have been changed. The inhibited instincts are capable of any degree of admixture with the uninhibited; they can be transformed back into them, just as they arose out of them. It is well known how easily erotic wishes develop out of emotional relations of a friendly character, based upon appreciation and admiration, (compare Molière's "*Embrassez-moi pour l'amour du grec*"<sup>1</sup>), between a master and a pupil, between a performer and a delighted listener, and especially in the case of women. In fact, the growth of emotional ties of this kind, with their purposeless beginnings, provides a much frequented pathway to sexual object-choice. Pfister, in his *Frömmigkeit des Grafen von Zinzendorf*,<sup>2</sup> has given an extremely clear and certainly not an isolated example of how easily even an intense religious tie can revert to ardent sexual excitement. On the other hand it is also very usual for directly sexual tendencies, short-lived in themselves, to be transformed into a lasting and purely tender tie; and the consolidation of a passionate love marriage rests to a large extent upon this process.

We shall naturally not be surprised to hear that the sexual tendencies that are inhibited in their aims arise out of the directly sexual ones when inner or outer obstacles make the sexual aims unattainable. The repression during the period of latency is an inner obstacle of this kind—or rather one which has become inner. We have assumed that the father of the primal horde, owing to his sexual intolerance, compelled all his sons to be abstinent, and thus forced them into ties that were inhibited in their aims, while he reserved for himself freedom of sexual enjoyment and in this way remained without ties. All the ties upon which a group depends are of the character of instincts that are inhibited in their aims. But here we have approached the discussion of a new subject,

which deals with the relation between directly sexual instincts and the formation of groups.

D. The last two remarks will have prepared us for finding that directly sexual tendencies are unfavourable to the formation of groups. In the history of the development of the family there have also, it is true, been group relations of sexual love (group marriages); but the more important sexual love became for the ego, and the more it developed the characteristics of being in love, the more urgently it required to be limited to two people—*una cum uno*—as is prescribed by the nature of the genital aim. Polygamous inclinations had to be content to find satisfaction in a succession of changing objects.

Two people coming together for the purpose of sexual satisfaction, in so far as they seek for solitude, are making a demonstration against the herd instinct, the group feeling. The more they are in love, the more completely they suffice for each other. The rejection of the group's influence is manifested in the shape of a sense of shame. The extremely violent feelings of jealousy are summoned up in order to protect the sexual object-choice from being encroached upon by a group tie. It is only when the tender, that is, the personal, factor of a love relation gives place entirely to the sensual one, that it is possible for two people to have sexual intercourse in the presence of others or for there to be simultaneous sexual acts in a group as occurs at an orgy. But at that point a regression has taken place to an early stage in sexual relations, at which being in love as yet played no part, and all sexual objects were judged to be of equal value, somewhat in the sense of Bernard Shaw's malicious aphorism to the effect that being in love means greatly exaggerating the difference between one woman and another.

There are abundant indications that being in love only made its appearance later on in the sexual relations between men and women; so that the opposition between sexual love and group ties is also a late development. Now it may seem as though this assumption were incompatible with our myth of the primal family. For it was after all by their love for their mothers and sisters that the troop of brothers was, as we have supposed, driven to parricide; and it is difficult to imagine this love as being anything but unbroken and primitive—that is, as an intimate union of the tender and the sensual. But further consideration resolves this objection into a confirmation. One of the re-

<sup>1</sup> Embrace me for the love of the Greek.—Ed.

<sup>2</sup> *Schriften zur angewandten Seelenkunde*. No. 8, Vienna, Deuticke, 1910.—Tr.

actions to the parricide was, after all, the institution of totemistic exogamy, the prohibition of any sexual relation with those women of the family who had been tenderly loved since childhood. In this way a wedge was driven in between a man's tender and sensual feelings, one still firmly fixed in his erotic life today.<sup>1</sup> As a result of this exogamy, the sensual needs of men had to be satisfied with strange and unloved women.

In the great artificial groups, the church and the army, there is no room for woman as a sexual object. The love relation between men and women remains outside these organizations. Even where groups are formed which are composed of both men and women, the distinction between the sexes plays no part. There is scarcely any sense in asking whether the libido which keeps groups together is of a homosexual or of a heterosexual nature, for it is not differentiated according to the sexes, and particularly shows a complete disregard for the aims of the genital organization of the libido.

Even in a person who has in other respects become absorbed in a group, the directly sexual tendencies preserve a little of his individual activity. If they become too strong, they disintegrate every group formation. The Catholic Church had the best of motives for recommending its followers to remain unmarried and for imposing celibacy upon its priests; but falling in love has often driven even priests to leave the church. In the same way, love for women breaks through the group ties of race, of national separation, and of the social class system, and it thus produces important effects as a factor in civilization. It seems certain that homosexual love is far more compatible with group ties, even when it takes the shape of uninhibited sexual tendencies—a remarkable fact, the explanation of which might carry us far.

The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms are to be traced back to directly sexual tendencies which are repressed but still remain active. We can complete this formula by adding to it: or, to tendencies inhibited in their aims, whose inhibition has not been entirely successful or has made room for a return to the repressed sexual aim. It is in accordance with this that a neurosis should make its victim asocial and should remove him from the usual group formations. It may be said that a neurosis has the same disintegrating effect upon a

group as being in love. On the other hand, it appears that where a powerful impetus has been given to group formation neuroses may diminish and, at all events, temporarily disappear. Justifiable attempts have also been made to turn this antagonism between neuroses and group formation to therapeutic account. Even those who do not regret the disappearance of religious illusions from the civilized world of today will admit that so long as they were in force they offered those who were bound by them the most powerful protection against the danger of neurosis. Nor is it hard to discern in all the ties with mystico-religious or philosophico-religious sects and communities the manifestation of distorted cures of all kinds of neuroses. All of this is bound up with the contrast between directly sexual tendencies and those which are inhibited in their aims.

If he is left to himself, a neurotic is obliged to replace by his own symptom formations the great group formations from which he is excluded. He creates his own world of imagination for himself, his own religion, his own system of delusions, and thus recapitulates the institutions of humanity in a distorted way which is clear evidence of the dominating part played by the directly sexual tendencies.<sup>2</sup>

E. In conclusion, we will add a comparative estimate, from the standpoint of the libido theory, of the states with which we have been concerned, of being in love, of hypnosis, of group formation, and of the neurosis.

*Being in love* is based upon the simultaneous presence of directly sexual tendencies and of sexual tendencies that are inhibited in their aims, so that the object draws a part of the narcissistic ego-libido to itself. It is a condition in which there is only room for the ego and the object.

*Hypnosis* resembles being in love in being limited to these two persons, but it is based entirely upon sexual tendencies that are inhibited in their aims and substitutes the object for the ego ideal.

*The group* multiplies this process; it agrees with hypnosis in the nature of the instincts which hold it together, and in the replacement of the ego ideal by the object; but to this it adds identification with other individuals, which was perhaps originally made possible by their having the same relation to the object.

Both states, hypnosis and group formation, are an inherited deposit from the phylogenesis

<sup>1</sup> See "The Most Prevalent Form of Degradation in Erotic Life."

<sup>2</sup> See *Totem and Taboo*, towards the end of Part II, "Totem and the Ambivalence of Emotions."

of the human libido—hypnosis in the form of a predisposition, and the group, besides this, as a direct survival. The replacement of the directly sexual tendencies by those that are inhibited in their aims promotes in both states a separation between the ego and the ego ideal, a separation with which a beginning has already been made in the state of being in love.

The *neurosis* stands outside this series. It also is based upon a peculiarity in the development of the human libido—the twice repeated start made by the directly sexual function, with an intervening period of latency.<sup>1</sup> To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appear-

ance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been completely successful; and it represents a *conflict* between those instincts which have been received into the ego after having passed through this development and those portions of the same instincts which, like other instinctive desires that have been completely repressed, strive, from the repressed unconscious, to attain direct satisfaction. The neurosis is extraordinarily rich in content, for it embraces all possible relations between the ego and the object—both those in which the object is retained and others in which it is abandoned or erected inside the ego itself—and also the conflicting relations between the ego and its ego-ideal.

# The Ego and the Id

## INTRODUCTION

IN my essay, *Beyond the Pleasure Principle*, published in 1920, I began the discussion of a train of thought, my personal attitude towards which, as I mentioned there, might be described as a sort of benevolent curiosity; in the following pages this train of thought is developed further. I have taken up those ideas and brought them into connection with various facts observed in psycho-analysis and have endeavoured to draw fresh conclusions from the combination; in the present work, however, no further contributions are levied from biology, and it consequently stands in a closer relation to psycho-analysis than does *Beyond the Pleasure Principle*. The thoughts contained in it are synthetic rather than speculative in character and their aim appears to be an ambitious one. I am aware, however, that they do not go beyond the baldest outlines and I am perfectly content to recognize their limitations in this respect.

At the same time, the train of thought touches upon things not hitherto dealt with in the work psycho-analysis has done, and it cannot avoid concerning itself with a number of theories propounded by non-analysts or by former analysts on their retreat from analysis. I am, as a rule, always ready to acknowledge my debts to other workers, but on this occasion I feel myself under no such obligation. If there are certain things to which hitherto psycho-analysis has not given adequate consideration, that is not because it has overlooked their effects or wished to deny their significance, but because it pursues a particular path which had not yet carried it so far. And, moreover, now that these things have at last been overtaken, they appear to psycho-analysis in a different shape from that in which they appear to the other people.

## I. CONSCIOUSNESS AND THE UNCONSCIOUS

IN this preliminary chapter there is nothing new to be said and it will not be possible to avoid repeating what has often been said before.

The division of mental life into what is conscious and what is unconscious is the fundamental premise on which psycho-analysis is based; and this division alone makes it possible

for it to understand pathological mental processes, which are as common as they are important, and to co-ordinate them scientifically. Stated once more in a different way: psycho-analysis cannot accept the view that consciousness is the essence of mental life, but is obliged to regard consciousness as one property of mental life, which may co-exist along with its other properties or may be absent.

If I were to allow myself to suppose that every one interested in psychology would read this book, I should still be prepared to find that some of them would stop short even at this point and go no further; for here we have the first shibboleth of psycho-analysis. To most people who have had a philosophical education, the idea of anything mental which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the mental phenomena of hypnosis and dreams, which—quite apart from pathological manifestations—necessitate this conclusion. Thus, their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.

The term *conscious* is, to start with, a purely descriptive one, resting on a perception of the most direct and certain character. Experience shows, next, that a mental element (for instance, an idea) is not as a rule permanently conscious. On the contrary, a state of consciousness is characteristically very transitory; an idea that is conscious now is no longer so a moment later, although it can become so again under certain conditions that are easily brought about. What the idea was in the interval we do not know. We can say that it was *latent*, and by this we mean that it was *capable of becoming conscious* at any time. Or, if we say that it was *unconscious*, we are giving an equally correct description. Thus, *unconscious* in this sense of the word coincides with *latent and capable of becoming conscious*. The philosophers would no doubt object: "No, the term unconscious does not apply here; so long as the idea was in a state of latency, it was not a mental element at all." To contradict them at this point would lead to nothing more profitable than a war of words.

But we have arrived at the term or concept of *unconscious* along another path, by taking account of certain experiences in which mental dynamics play a part. We have found, that is, we have been obliged to assume, that very powerful mental processes or ideas exist—here a quantitative or *economic* factor comes into question for the first time—which can produce in the mind all the effects that ordinary ideas do (including effects that can in their turn become conscious as ideas) without themselves becoming conscious. It is unnecessary here to repeat in detail what has been explained so often before. We need only say that this is the point at which psycho-analytic theory steps in—with the assertion that such ideas cannot become conscious because a certain force is opposed to them, that, otherwise, they could become conscious, and that then one would see how little they differ from other elements which are admittedly mental. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us *repression*, and we assert that the force which instituted the repression and maintains it is perceived as *resistance* during the work of analysis.

We obtain our concept of the unconscious, therefore, from the theory of repression. The repressed serves us as a prototype of the unconscious. We see, however, that we have two kinds of unconscious—that which is latent but capable of becoming conscious, and that which is repressed and not capable of becoming conscious in the ordinary way. This piece of insight into mental dynamics cannot fail to affect terminology and description. That which is latent, and only unconscious in the descriptive and not in the dynamic sense, we call *preconscious*; the term *unconscious* we reserve for the dynamically unconscious repressed, so that we now have three terms, conscious (*Cs*), *preconscious* (*Pcs*), and unconscious (*Ucs*), which are no longer purely descriptive in sense. The *Pcs* is presumably a great deal closer to the *Cs* than is the *Ucs*, and since we have called the *Ucs* mental we shall with even less hesitation call the latent *Pcs* mental. But why do we not choose, instead of this, to remain in agreement with the philosophers and, in a consistent way, to distinguish the *Pcs* as well as the *Ucs* from what is conscious in the mind? The philosophers would propose that both the *Pcs* and

the *Ucs* should be described as two varieties or levels of *psychoïd*, and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that the two kinds of *psychoïd*, as thus defined, coincide in almost every other respect with what is admittedly mental, would be forced into the background in the interests of a prejudice dating from a period in which they, or the most important part of them, were still unknown.

We can now set to work comfortably with our three terms, *Cs*, *Pcs*, and *Ucs*, so long as we do not forget that, while in the descriptive sense there are two kinds of unconscious, in the dynamic sense there is only one. For purposes of exposition this distinction can in many cases be ignored, but in others it is, of course, indispensable. At the same time, we have become more or less accustomed to these two meanings of the term *unconscious* and have managed pretty well with them. As far as I can see, it is impossible to avoid this ambiguity; the distinction between conscious and unconscious is in the last resort a question of a perception which must be either affirmed or denied, and the act of perception itself tells us nothing of the reason why a thing is or is not perceived. No one has a right to complain because the actual phenomenon expresses the underlying dynamic factors ambiguously.<sup>1</sup>

<sup>1</sup> This may be compared with my "Note on the Unconscious in Psycho-Analysis" (1912), *Collected Papers*, IV. A new turn taken by criticisms of the unconscious deserves consideration at this point. Many investigators, who do not refuse to recognize the facts of psycho-analysis but who are unwilling to accept the unconscious, find a way out of the difficulty in the fact, which no one contests, that in consciousness (regarded as a phenomenon) it is possible to distinguish a great variety of gradations in intensity or clarity. Just as there are ideas which are very vividly, keenly, and definitely conscious, so we also entertain others which are but faintly, hardly even noticeably conscious; those that are most faintly conscious are, it is argued, the ones to which psycho-analysis wishes to apply the unsuitable name *unconscious*. These, however (the argument proceeds), are also conscious or in *consciousness* just as much as the others, and can be made fully and intensely conscious if sufficient attention is paid to them.

In so far as it is possible to influence by arguments the decision of a question of this kind which is based either on a convention or on emotional factors, we may make the following comments. The reference to gradations of clarity in consciousness is in no way conclusive and has no more evidential value than such analogous statements as: "There are so many gradations in illumination—from the brightest and most dazzling light to the dimmest glimmer—that we may conclude that there is no such thing as darkness at all", or, "There are varying degrees of vitality, consequently there is no such thing as death." Such statements may, in a certain sense, have a meaning, but for practical purposes they are worthless. This will be seen if one proceeds to draw certain conclusions

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formulated the idea that in every individual there is a coherent organization of mental processes, which we call his *ego*. This ego includes consciousness, and it controls the approaches to motility, i.e., to the discharge of excitations into the external world; it is this institution in the mind which regulates all its own constituent processes, and which goes to sleep at night, though even then it continues to exercise a censorship upon dreams. From this ego proceed the repressions, too, by means of which an attempt is made to cut off certain trends in the mind not merely from consciousness but also from their other forms of manifestation and activity. In analysis these trends which have been shut out stand in opposition to the ego and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find that, during analysis, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they ought to be getting near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his feelings of discomfort that a resistance is now at work in him, he does not know what it is nor how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We

---

from them, such as, "it is not necessary, therefore, to strike a light," or, "therefore, all living things are immortal." Further, to include *what is unnoticeable* under the concept of *what is conscious* is simply to play havoc with the one and only piece of direct and certain knowledge that we have about the mind. And after all, a consciousness of which one knows nothing seems to me a good deal more absurd than an unconscious mind. Finally, this attempt to equate what is unnoticed with what is unconscious is obviously made without taking into account the dynamic conditions involved, which were the decisive factors in formulating the psycho-analytic view. For it ignores two facts: first, that it is exceedingly difficult and requires very great effort to concentrate enough attention on something unnoticed of this kind; and secondly, that when this has been achieved, the thought which was previously unnoticed is not recognized by consciousness, but often seems utterly alien and opposed to it and is promptly disavowed by it. Escaping from the unconscious in this way and taking refuge in what is scarcely noticed or unnoticed is, therefore, after all, only an expression of the preconceived belief which regards the identity of mental and conscious as settled once and for all.

have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed, that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this piece of observation is that we land in endless confusion and difficulty if we cling to our former way of expressing ourselves and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our understanding of the structural conditions of the mind, namely, the antithesis between the organized ego and what is repressed and dissociated from it.<sup>1</sup>

For our conception of the unconscious, however, the consequences of our new observation are even more important. Dynamic considerations caused us to make our first correction; our knowledge of the structure of the mind leads to the second. We recognize that the *Ucs* does not coincide with what is repressed; it is still true that all that is repressed is *Ucs*, but not that the whole *Ucs* is repressed. A part of the ego, too—and Heaven knows how important a part—may be *Ucs*, undoubtedly is *Ucs*. And this *Ucs* belonging to the ego is not latent like the *Pcs*; for if it were, it could not be activated without becoming *Cs*, and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third *Ucs* which is not repressed, we must admit that the property of being unconscious begins to lose significance for us. It becomes a quality which can have many implications, so that we are unable to make it, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless, we must beware of ignoring this property, for, in the last resort, the quality of being conscious or not is the single ray of light that penetrates the obscurity of depth-psychology.

## II. THE EGO AND THE ID

**PATHOLOGICAL** research has centred our interest too exclusively on the repressed. We wish to know more about the ego, now that we know that it, too, can be *unconscious* in the proper sense of the word. Hitherto, the only guide we have had while pursuing our investigations has been the distinguishing mark of

<sup>1</sup> See *Beyond the Pleasure Principle*, p. 639 above.

being conscious or unconscious; and in the end we have come to see that this quality itself is ambiguous.

Now, all our knowledge is invariably bound up with consciousness. Even knowledge of the *Ucs* can only be obtained by making it conscious. But stop, how is that possible? What does it mean when we say "making it conscious"? How can that come about?

We already know the point from which we have to start in this connection. We have said that consciousness is the *superficies* of the mental apparatus; that is, we have allocated it as a function to the system which is situated nearest to the external world. Incidentally, on this occasion the topographical terminology does not merely serve to describe the nature of the function, but actually corresponds to the anatomical facts.<sup>1</sup> Our investigations too must take this surface organ of perception as a starting-point.

All perceptions which are received from without (sense-perceptions) and from within—what we call sensations and feelings—are *Cs* from the start. But how is it with those internal processes which we may—vaguely and inexact—sum up under the name of *thought-processes*? They represent displacements of mental energy which are effected somewhere in the interior of the apparatus as this energy proceeds on its way towards action. Do they advance towards the superficies, which then allows of the development of consciousness? Or does consciousness make its way towards them? This is clearly one of the difficulties that spring up when one begins to take the spatial or *topographical* conception of mental life seriously. Both these possibilities are equally unimaginable; there must be a third contingency to meet the case.

I have already, in another place,<sup>2</sup> suggested that the real difference between a *Ucs* and a *Pcs* idea (thought) consists in this: that the former is worked out upon some sort of material which remains unrecognized, whereas the latter (the *Pcs*) has in addition been brought into connection with verbal images. This is the first attempt to find a distinguishing mark for the two systems, the *Pcs* and the *Ucs*, other than their relation to consciousness. It would seem, then, that the question, "How does a thing become conscious?" could be put more advantageously thus: "How does a thing become preconscious?" And the answer would be: "By

coming into connection with the verbal images that correspond to it."

These verbal images are memory-residues; they were at one time perceptions, and like all memory-residues they can become conscious again. Before we concern ourselves further with their nature, it dawns upon us like a new discovery that only something which has once been a *Cs* perception can become conscious, and that anything arising from within (apart from feelings) that seeks to become conscious must try to transform itself into external perceptions: this can be done by way of memory-traces.

We conceive of memory-residues as contained in systems which are directly adjacent to the system *Pcpt-Cs*, so that the cathexes pertaining to the memory-residues can readily extend outward on to the elements of the latter system. We are immediately reminded of hallucinations here, and of the fact that the most vivid memory is always distinguishable both from a hallucination and from an external perception; but it will also occur to us that when a memory is revived the cathexis in the memory-system will remain in force, whereas a hallucination which is not distinguishable from a perception can arise when the cathexis does not merely extend over from the memory-trace to the *Pcpt*-element, but passes over to it entirely.

Verbal residues are derived primarily from auditory perceptions, so that the system *Pcs* has, as it were, a special sensory source. The visual components of verbal images are secondary, acquired through reading, and may, to begin with, be left on one side; so may the sensory-motor images of words, which, except with deaf-mutes, play an auxiliary part. The essence of a word is, after all, the memory-trace of a word that has been heard.

We must not be led away, in the interests of simplification perhaps, into forgetting the importance of optical memory-residues—those of *things* (as opposed to *words*)—or to deny that it is possible for thought-processes to become conscious through a reversion to visual residues, and that in many people this seems to be a favourite method. The study of dreams and of preconscious phantasies on the lines of J. Varendonck's observations gives us an idea of the special character of this visual thinking. We learn that what becomes conscious is, as a rule, only the concrete subject-matter of the thought, and that the relations between the various elements of this subject-matter, which is what specially characterizes thought, cannot

<sup>1</sup> *Beyond the Pleasure Principle*, p. 639 above.

<sup>2</sup> *The Unconscious*, p. 428 above.

be given visual expression. Thinking in pictures is, therefore, only a very incomplete form of becoming conscious. In some way, too, it approximates more closely to unconscious processes than does thinking in words, and it is unquestionably older than the latter both ontogenetically and phylogenetically.

To return to our argument: if, therefore, this is the way in which something that is in itself unconscious becomes preconscious, the question how something that is repressed can be made (pre)conscious would be answered as follows. It is done by supplying through the work of the analysis *Pcs* connecting-links of the kind we have been discussing. Consciousness remains where it is, therefore; but, on the other hand, the *Ucs* does not rise up into the *Cs*.

Whereas the relation between external perceptions and the ego is quite perspicuous, that between internal perceptions and the ego requires special investigation. It gives rise once more to a doubt whether we are really justified in referring the whole of consciousness to the single superficial system *Pcpt-Cs*.

Internal perceptions yield sensations of processes arising in the most diverse and certainly also in the deepest strata of the mental apparatus. Very little is known about these sensations and feelings; the best examples we have of them are still those belonging to the pleasure-pain series. They are more fundamental, more elementary, than perceptions arising externally, and they can come into being even when consciousness is clouded. I have elsewhere expressed my views about their great economic significance and its metapsychological foundation. These sensations are multi-ocular, like external perceptions; they may come from different places simultaneously and may thus have different or even opposite qualities.

Sensations of a pleasurable nature are not characterized by any inherently impelling quality, whereas "painful" ones possess this quality in a high degree. The latter impel towards change, towards discharge, and that is why we interpret "pain" as implying a heightening and pleasure a lowering of energetic cathexis. Suppose we describe what becomes conscious in the shape of pleasure and "pain" as an undetermined quantitative and qualitative element in the mind; the question then is whether that element can become conscious where it actually is, or whether it must first be transmitted into the system *Pcpt*.

Clinical experience decides for the latter. It shows us that this undetermined element be-

haves like a repressed impulse. It can exert driving force without the ego noticing the compulsion. Not until there is resistance to the compulsion, and blocking of the discharge-reaction, does the undetermined element instantly become conscious as "pain." In the same way that tensions arising from physical need can remain unconscious, so also can physical pain—a thing intermediate between external and internal perception, which acts like an internal perception even when its source is in the external world. It remains true again, therefore, that sensations and feelings only become conscious through reaching the system *Pcpt*; if the way forward is barred, they do not come into being as sensations, although the undetermined element corresponding to them is the same as if they did. We then come to speak, in a condensed and not entirely correct manner, of *unconscious feelings*, keeping up an analogy with unconscious ideas which is not altogether justifiable. Actually the difference is that, whereas with *Ucs ideas* connecting-links must be forged before they can be brought into the *Cs*, with *feelings*, which are themselves transmitted directly, there is no necessity for this. In other words: the distinction between *Cs* and *Pcs* has no meaning where feelings are concerned; the *Pcs* here falls out of account, and feelings are either conscious or unconscious. Even when they are connected with verbal images, their becoming conscious is not due to that circumstance, but they become so directly.

The part played by verbal images now becomes perfectly clear. By their interposition, internal thought-processes are made into perceptions. It is like a demonstration of the theorem that all knowledge has its origin in external perception. It may sometimes happen that a hyper-cathexis of the process of thinking takes place, in which case thoughts are *perceived* in the literal sense of the word—as if they came from without—and are consequently held to be true.

After this clarifying of the relations between external and internal perception and the superficial system *Pcpt-Cs*, we can go on to work out our conception of the ego. It clearly starts out from its nucleus, the system *Pcpt*, and begins by embracing the *Pcs*, which is adjacent to the memory-residues. But the ego, as we have learnt, is also unconscious.

Now I think we shall gain a great deal by following the suggestion of a writer who, from personal motives, vainly insists that he has nothing to do with the rigours of pure science.

I am speaking of Georg Groddeck, who is never tired of pointing out that the conduct through life of what we call our ego is essentially passive, and that, as he expresses it, we are "lived" by unknown and uncontrollable forces.<sup>1</sup> We have all had impressions of the same kind, even though they may not have overwhelmed us to the exclusion of all others, and we need feel no hesitation in finding a place for Groddeck's discovery in the fabric of science. I propose to take it into account by calling the entity which starts out from the system *Pcpt* and begins by being *Pcs* the *ego*, and by following Groddeck in giving to the other part of the mind, into which this entity extends and which behaves as though it were *Ucs*, the name of *Id* (*Es*).<sup>2</sup>

We shall soon see whether this conception affords us any gain in understanding or any advantage for purposes of description. We shall now look upon the mind of an individual as an unknown and unconscious id, upon whose surface rests the ego, developed from its nucleus the *Pcpt*-system. If we make an effort to conceive of this pictorially, we may add that the ego does not envelop the whole of the id, but only does so to the extent to which the system *Pcpt* forms its surface, more or less as the germinal layer rests upon the ovum. The ego is not sharply separated from the id; its lower portion merges into it.

But the repressed merges into the id as well, and is simply a part of it. The repressed is only cut off sharply from the ego by the resistances

lining by our study of pathology relate only to the superficial levels of the mental apparatus—the only ones known to us. The state of things which we have been describing can be represented diagrammatically (Fig. 1); though it must be remarked that the form chosen has no pretensions to any special applicability, but is merely intended to serve for purposes of exposition. We might add, perhaps, that the *ego* wears an auditory lobe—on one side only, as we learn from cerebral anatomy. It wears it crooked, as one might say.

It is easy to see that the ego is that part of the id which has been modified by the direct influence of the external world acting through the *Pcpt-Cs*: in a sense it is an extension of the surface-differentiation. Moreover, the ego has the task of bringing the influence of the external world to bear upon the id and its tendencies, and endeavours to substitute the reality-principle for the pleasure-principle which reigns supreme in the id. In the ego, perception plays the part which in the id devolves upon instinct. The ego represents what we call reason and sanity, in contrast to the id which contains the passions. All this falls into line with popular distinctions which we are all familiar with; at the same time, however, it is only to be regarded as holding good in an average or "ideal" case.

The functional importance of the ego is manifested in the fact that normally control over the approaches to motility devolves upon it. Thus in its relation to the id it is like a man on horseback, who has to hold in check the superior strength of the horse; with this difference, that the rider seeks to do so with his own strength while the ego uses borrowed forces. The illustration may be carried further. Often a rider, if he is not to be parted from his horse, is obliged to guide it where it wants to go; so in the same way the ego constantly carries into action the wishes of the id as if they were its own.

It seems that another factor, besides the influence of the system *Pcpt*, has been at work in bringing about the formation of the ego and its differentiation from the id. The body itself, and above all its surface, is a place from which both external and internal perceptions may spring. It is seen in the same way as any other object, but to the touch it yields two kinds of sensations, one of which is equivalent to an internal perception. Psychophysiology has fully discussed the manner in which the body attains its special position among other objects in the

Fig. 1.

of repression; it can communicate with the ego through the id. We at once realize that almost all the delimitations we have been led into out-

<sup>1</sup> G. Groddeck, *Das Buch vom Es*, Vienna, 1923.

<sup>2</sup> Groddeck himself no doubt followed the example of Nietzsche, who habitually used this grammatical term for whatever in our nature is impersonal and, so to speak, subject to natural law.

world of perception. Pain seems also to play a part in the process, and the way in which we gain new knowledge of our organs during painful illnesses is perhaps a prototype of the way by which in general we arrive at the idea of our own body.

The ego is first and foremost a body-ego; it is not merely a surface entity, but it is itself the projection of a surface.<sup>1</sup> If we wish to find an anatomical analogy for it we can easily identify it with the *cortical homunculus* of the anatomists, which stands on its head in the cortex, sticks its heels into the air, faces backwards and, as we know, has its speech-area on the left-hand side.

The relation of the ego to consciousness has been gone into repeatedly; yet there are still some important facts in this connection which remain to be described. Accustomed as we are to taking our social or ethical standard of values along with us wherever we go, we feel no surprise at hearing that the scene of the activities of the lower passions is in the unconscious; we expect, moreover, that the higher any mental function ranks in our scale of values, the more easily it will find access to consciousness assured to it. Here, however, psycho-analytic experience disappoints us. On the one hand, we have evidence that even subtle and intricate intellectual operations which ordinarily require strenuous concentration can equally be carried out preconsciously and without coming into consciousness. Instances of this are quite incontestable; they may occur, for instance, during sleep, as is shown when some one finds, immediately after waking, that he knows the solution of a difficult mathematical or other problem with which he had been wrestling in vain the day before.<sup>2</sup>

There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience—mental activities that is, that rank as exceptionally high ones—are unconscious and unconsciously produce effects of the greatest importance; the example of resistances remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels

us, in spite of our critical faculties, to speak of an *unconscious sense of guilt*, bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that, in a great number of neuroses, this unconscious sense of guilt plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego.

### III. THE EGO AND THE SUPER-EGO (EGO-IDEAL)

If the ego were merely the part of the id that is modified by the influence of the perceptual system, the representative in the mind of the real external world, we should have a simple state of things to deal with. But there is a further complication.

The considerations that led us to assume the existence of a differentiating grade within the ego, which may be called the *ego-ideal* or *super-ego*, have been set forth elsewhere.<sup>3</sup> They still hold good.<sup>4</sup> The new proposition which must now be gone into is that this part of the ego is less closely connected with consciousness than the rest.

At this point, we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that, in those suffering from it, an object which was lost has been reinstated within the ego; that is, that an object-cathexis has been replaced by an identification.<sup>5</sup> When this explanation was first proposed, however, we did not appreciate the full significance of the process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken on by the ego and that it contributes materially towards building up what is called its *character*.

<sup>3</sup> *On Narcissism: an Introduction* [p. 399 above]; and *Group Psychology and the Analysis of the Ego* [p. 664 above].

<sup>4</sup> Except that I seem to have been mistaken in ascribing the function of testing the reality of things to this super-ego—a point which needs correction. The view that the testing of reality is rather one of the functions of the ego itself would fit in perfectly with what we know of the relations of the ego to the world of perception. Some earlier suggestions about a "nucleus of the ego," never very definitely formulated, also require to be put right, since the system *Pcpt-Cs* alone can be regarded as the nucleus of the ego.

<sup>5</sup> "Mourning and Melancholia," (1917), *Collected Papers*, IV.

<sup>1</sup> *I.e.*, the ego is ultimately derived from bodily sensations, chiefly from those springing from the surface of the body. It may thus be regarded as a mental projection of the surface of the body, besides, as we have seen above, representing the superficialities of the mental apparatus.—Authorized note by the Translator.

<sup>2</sup> I was quite recently told an instance of this which was, in fact, brought up as an objection against my description of the "dream-work."

At the very beginning, in the primitive oral phase of the individual's existence, object-cathexis and identification are hardly to be distinguished from each other. We can only suppose that, later on, object-cathexes proceed from the id, in which erotic trends are felt as needs. The ego, which at its inception is still far from robust, becomes aware of the object-cathexes, and either acquiesces in them or tries to defend itself against them by the process of repression.<sup>1</sup>

When it happens that a person has to give up a sexual object, there quite often ensues a modification in his ego which can only be described as a reinstatement of the object within the ego, as it occurs in melancholia; the exact nature of this substitution is as yet unknown to us. It may be that, by undertaking this introjection, which is a kind of regression to the mechanism of the oral phase, the ego makes it easier for an object to be given up or renders that process possible. It may even be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it points to the conclusion that the character of the ego is a precipitate of abandoned object-cathexes and that it contains a record of past object-choices. It must, of course, be admitted from the outset that there are varying degrees of capacity for resistance, as shown by the extent to which the character of any particular person accepts or resists the influences of the erotic object-choices through which he has lived. In women who have had many love-affairs there seems to be no difficulty in finding vestiges of their object-cathexes in the traits of their character. We must also take into consideration the case of simultaneous object-cathexis and identification, i.e., in which the alteration in character occurs before the object has been given up. In such a case, the alteration in character would be able to survive the object-relation and, in a certain sense, to conserve it.

From another point of view it may be said that this transformation of an erotic object-

choice into a modification of the ego is also a method by which the ego can obtain control over the id and deepen its relations with it—at the cost, it is true, of acquiescing to a large extent in the id's experiences. When the ego assumes the features of the object, it forces itself, so to speak, upon the id as a love-object and tries to make good the loss of that object by saying, "Look, I am so like the object, you can as well love me."

The transformation of object-libido into narcissistic libido which thus takes place obviously implies an abandonment of sexual aims, a process of desexualization; it is consequently a kind of sublimation. Indeed, the question arises, and deserves careful consideration, whether this is not always the path taken in sublimation, whether all sublimation does not take place through the agency of the ego, which begins by changing sexual object-libido into narcissistic libido and then, perhaps, goes on to give it another aim.<sup>2</sup> We shall later on have to consider whether other instinctual vicissitudes may not also result from this transformation, whether, for instance, it may not bring about a defusion of the instincts that are fused together.

Although it is a digression from our theme, we cannot avoid giving our attention for a moment longer to the ego's object-identifications. If they obtain the upper hand and become too numerous, unduly intense and incompatible with one another, a pathological outcome will not be far off. It may come to a disruption of the ego in consequence of the individual identifications becoming cut off from one another by resistances; perhaps the secret of the cases of so-called *multiple personality* is that the various identifications seize possession of consciousness in turn. Even when things do not go so far as this, there remains the question of conflicts between the different identifications into which the ego is split up, conflicts which cannot after all be described as purely pathological.

But, whatever the character's capacity for resisting the influences of abandoned object-cathexes may turn out to be in after years, the effects of the first identifications in earliest childhood will be profound and lasting. This leads us back to the origin of the ego-ideal; for

<sup>1</sup> An interesting parallel to the replacement of object-choice by identification is to be found in the belief of primitive peoples, and in the taboos based upon it, that the attributes of animals which are assimilated as nourishment survive as part of the character of the persons who eat them. As is well known, this belief is one of the roots of cannibalism, and its effects can be traced throughout the series of customs derived from the totem feast down to the Holy Communion. The consequences ascribed by this belief to oral mastery of the object do, in fact, follow in the case of the later sexual object-choice.

<sup>2</sup> Now that we have distinguished between the ego and the id, we must recognize the id as the great reservoir of libido mentioned in my introductory paper *On Narcissism* (p. 399 above). The libido which flows into the ego owing to the identifications described above brings about its "secondary narcissism."

behind the latter there lies hidden the first and most important identification of all, the identification with the father,<sup>1</sup> which takes place in the prehistory of every person. This is apparently not in the first instance the consequence or outcome of an object-cathexis; it is a direct and immediate identification and takes place earlier than any object-cathexis. But the object-choices belonging to the earliest sexual period and relating to the father and mother seem normally to find their outcome in an identification of the kind discussed, which would thus reinforce the primary one.

The whole subject, however, is so complicated that it will be necessary to go into it more minutely. The intricacy of the problem is due to two factors: the triangular character of the Oedipus situation, and the constitutional bisexuality of each individual.

In its simplified form, the case of the male child may be described as follows. At a very early age the little boy develops an object-cathexis of his *mother*, which originally related to the mother's breast and is the earliest instance of an object-choice on the anaclitic model; his *father* the boy deals with by identifying himself with him. For a time these two relationships exist side by side, until the sexual wishes in regard to the mother become more intense and the father is perceived as an obstacle to them; this gives rise to the Oedipus complex.<sup>2</sup> The identification with the father then takes on a hostile colouring and changes into a wish to get rid of the father in order to take his place with the mother. Henceforward the relation to the father is ambivalent; it seems as if the ambivalence inherent in the identification from the beginning had become manifest. An ambivalent attitude to the father and an object-relation of a purely affectionate kind to the mother make up the content of the simple positive Oedipus complex in the boy.

Along with the dissolution of the Oedipus complex, the object-cathexis of the mother must be given up. Its place may be filled by one of two things: either an identification with

the mother or an intensified identification with the father. We are accustomed to regard the latter outcome as the more normal; it permits the affectionate relation to the mother to be in a measure retained. In this way the passing of the Oedipus complex would consolidate the masculinity in the boy's character. In a precisely analogous way, the outcome of the Oedipus attitude in the little girl may be an intensification of the identification with her mother (or such an identification may thus be set up for the first time)—a result which will stamp the child's character in the feminine mould.

These identifications are not what our previous statements would have led us to expect, since they do not involve the absorption of the abandoned object into the ego: But this alternative outcome may also occur; it is more readily observed in girls than in boys. Analysis very often shows that a little girl, after she has had to relinquish her father as a love-object, will bring her masculinity into prominence and identify herself with her father, that is, with the object which has been lost, instead of with her mother. This will clearly depend on whether the masculinity in her disposition—whatever that may consist of—is strong enough.

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets the impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough adequate for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-relation towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding hostility and jealousy towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection

<sup>1</sup> Perhaps it would be safer to say "with the parents"; for before a child has arrived at definite knowledge of the difference between the sexes, the missing penis, it does not distinguish in value between its father and its mother. I recently came across the instance of a young married woman whose story showed that, after noticing the lack of a penis in herself, she had supposed it to be absent not in all women, but only in those whom she regarded as inferior, and had still supposed that her mother possessed one.

In order to simplify my presentment, I shall discuss only identification with the father.

<sup>2</sup> Cf. *Group Psychology and the Analysis of the Ego*, chap. VII [p. 678 above].

with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I stated just now, developed out of an identification in consequence of rivalry.

In my opinion, it is advisable in general, and quite especially where neurotics are concerned, to assume the existence of the complete Oedipus complex. Analytic experience then shows that in a number of cases one or the other of its constituents disappears, except for barely distinguishable traces, so that a series can be formed with the normal positive Oedipus complex at one end and the inverted negative one at the other, while its intermediate members will exhibit the complete type with one or other of its two constituents preponderating. As the Oedipus complex dissolves, the four trends of which it consists will group themselves in such a way as to produce a father-identification and a mother-identification. The father-identification will preserve the object-relation to the mother which belonged to the positive complex and will at the same time take the place of the object-relation to the father which belonged to the inverted complex: and the same will be true *mutatis mutandis*,<sup>1</sup> of the mother-identification. The relative intensity of the two identifications in any individual will reflect the preponderance in him of one or other of the two sexual dispositions.

*The broad general outcome of the sexual phase governed by the Oedipus complex may, therefore, be taken to be the forming of a precipitate in the ego, consisting of these two identifications in some way combined together. This modification of the ego retains its special position; it stands in contrast to the other constituents of the ego in the form of an ego-ideal or super-ego.*

The super-ego is, however, not merely a deposit left by the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: "You ought to be such and such (like your father)"; it also comprises the prohibition: "You must not be such and such (like your father)"; that is, you may not do all that he does; many things are his prerogative." This double aspect of the ego-ideal derives from the fact that the ego-ideal had the task of effecting the repression of the Oedipus complex, indeed, it is to

that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The parents, and especially the father, were perceived as the obstacle to realization of the Oedipus wishes; so the child's ego brought in a reinforcement to help in carrying out the repression by erecting this same obstacle within itself. The strength to do this was, so to speak, borrowed from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more intense the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of discipline, religious teaching, schooling and reading), the more exacting later on is the domination of the super-ego over the ego—in the form of conscience or perhaps of an unconscious sense of guilt. I shall later on bring forward a suggestion about the source of the power it employs to dominate in this way, the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.

If we consider once more the origin of the super-ego as we have described it, we shall perceive it to be the outcome of two highly important factors, one of them biological and the other historical: namely, the lengthy duration in man of the helplessness and dependence belonging to childhood, and the fact of his Oedipus complex, the repression of which we have shown to be connected with the interruption of libidinal development by the latency period and so with the twofold onset of activity characteristic of man's sexual life.<sup>2</sup> According to the view of one psycho-analyst, the last-mentioned phenomenon, which seems to be peculiar to man, is a heritage of the cultural development necessitated by the glacial epoch. We see, then, that the differentiation of the super-ego from the ego is no matter of chance; it stands as the representative of the most important events in the development both of the individual and of the race; indeed, by giving permanent expression to the influence of the parents, it perpetuates the existence of the factors to which it owes its origin.

Psycho-analysis has been reproached time after time with ignoring the higher, moral, spiritual side of human nature. The reproach is doubly unjust, both historically and methodologically. For, in the first place, we have

<sup>2</sup> This sentence represents a slight modification of the original text in accordance with direct instructions from the author.—TR.

<sup>1</sup> The necessary changes being made.—ED.

from the very beginning attributed the function of instigating repression to the moral and aesthetic tendencies in the ego; and secondly, there has been a general refusal to recognize that psycho-analytic research could not produce a complete and finished body of doctrine, like a philosophical system, ready-made, but had to find its way step by step along the path towards understanding the intricacies of the mind by making an analytic dissection of both normal and abnormal phenomena. So long as the study of the repressed part of the mind was our task, there was no need for us to feel any agitated apprehensions about the existence of the higher side of mental life. But now that we have embarked upon the analysis of the ego, we can give an answer to all those whose moral sense has been shocked and who have complained that there must surely be a higher nature in man: "Very true," we can say, "and here we have that higher nature, in this ego-ideal or super-ego, the representative of our relation to our parents. When we were little children we knew these higher natures, we admired them and feared them; and later we took them into ourselves."

The ego-ideal, therefore, is the heir of the Oedipus complex and thus it is also the expression of the most powerful impulses and most important vicissitudes experienced by the libido in the id. By setting up this ego-ideal, the ego masters its Oedipus complex and at the same time places itself in subjection to the id. Whereas the ego is essentially the representative of the external world, of reality, the super-ego stands in contrast to it as the representative of the internal world, of the id. Conflicts between the ego and the ideal will, as we are now prepared to find, ultimately reflect the contrast between what is real and what is mental between the external world and the internal world.

Through the forming of the ideal, all the traces left behind in the id by biological developments and by the vicissitudes gone through by the human race are taken over by the ego and lived through again by it in each individual. Owing to the way in which it is formed, the ego-ideal has a great many points of contact with the phylogenetic endowment of each individual—his archaic heritage. And thus it is that what belongs to the lowest depths in the minds of each one of us is changed, through this formation of the ideal, into what we value as the highest in the human soul. It would be vain, however, to attempt to localize the ego-

ideal, even in the sense in which we have localized the ego, or to work it into any of those analogies with the help of which we have tried to picture the relation between the ego and the id.

It is easy to show that the ego-ideal answers in every way to what is expected of the higher nature of man. In so far as it is a substitute for the longing for a father, it contains the germ from which all religions have evolved. The self-judgment which declares that the ego falls short of its ideal produces the sense of worthlessness with which the religious believer attests his longing. As a child grows up, the office of father is carried on by masters and by others in authority; the power of their injunctions and prohibitions remains vested in the ego-ideal and continues, in the form of conscience, to exercise the censorship of morals. The tension between the demands of conscience and the actual attainments of the ego is experienced as a sense of guilt. Social feelings rest on the foundation of identifications with others, on the basis of an ego-ideal in common with them.

Religion, morality, and a social sense—the chief elements of what is highest in man<sup>1</sup>—were originally one and the same thing. According to the hypothesis which I have put forward in *Totem and Taboo*, they were acquired phylogenetically out of the father-complex: religion and moral restraint by the actual process of mastering the Oedipus complex itself, and social feeling from the necessity for overcoming the rivalry that then remained between the members of the younger generation. It seems that the male sex has taken the lead in developing all of these moral acquisitions; and that they have then been transmitted to women by cross-inheritance. Even today the social feelings arise in the individual as a superstructure founded upon impulses of jealousy and rivalry against his brothers and sisters. Since the enmity cannot be gratified, there develops an identification with the former rival. The study of mild cases of homosexuality confirms the suspicion that in this instance, too, the identification is a substitute for an affectionate object-choice which has succeeded the hostile, aggressive attitude.<sup>2</sup>

With the mention of phylogenesis, however,

<sup>1</sup> I am at the moment putting science and art on one side.

<sup>2</sup> Cf. *Group Psychology and the Analysis of the Ego* [p. 664 above]; and "Certain Neurotic Mechanisms in Jealousy, Paranoia, and Homosexuality" (1922), *Collected Papers*, II.

fresh problems arise, from which one is tempted to shrink back dismayed. But there is no help for it, the attempt must be made; in spite of a fear that it will lay bare the inadequacy of the whole structure that we have so arduously built up. The question is: which was it, the ego of primitive man or his id, that acquired religion and morality in those early days out of the father-complex? If it was his ego, why do we not speak simply of these things being inherited by the ego? If it was the id, how does that agree with the character of the id? Or are we wrong in carrying the differentiation between ego, super-ego, and id back into such early times? Or should we not honestly confess that our whole conception of the processes within the ego is of no help in understanding phylogenesis and cannot be applied to it?

Let us answer first what is easiest to answer. The differentiation between ego and id must be attributed not only to primitive man but even to much simpler forms of life, for it is the inevitable expression of the influence of the external world. The super-ego, according to our hypothesis, actually originated from the experiences that led to totemism. The question whether it was the ego or the id that experienced and acquired these things soon ceases to have any meaning. Reflection at once shows us that no external vicissitudes can be experienced or undergone by the id, except by way of the ego, which is the representative of the outer world to the id. Nevertheless it is not possible to speak of direct inheritance by the ego. It is here that the gulf between the actual individual and the conception of the species becomes evident. Moreover, one must not take the difference between ego and id in too hard-and-fast a sense, nor forget that the ego is a part of the id which has been specially modified. The experiences undergone by the ego seem at first to be lost to posterity; but, when they have been repeated often enough and with sufficient intensity in the successive individuals of many generations, they transform themselves, so to say, into experiences of the id, the impress of which is preserved by inheritance. Thus in the id, which is capable of being inherited, are stored up vestiges of the existences led by countless former egos; and, when the ego forms its super-ego out of the id, it may perhaps only be reviving images of egos that have passed away and be securing them a resurrection.

The way in which the super-ego came into being explains how it is that the earlier con-

licts of the ego with the object-cathexes of the id can be carried on and continued in conflicts with their successor, the super-ego. If the ego has not succeeded in mastering the Oedipus complex satisfactorily, the energetic cathexis of the latter, springing from the id, will find an outlet in the reaction-formations of the ego-ideal. The very free communication possible between the ideal and these *Ucs* instinctual trends explains how it is that the ideal itself can be to a great extent unconscious and inaccessible to the ego. The struggle which once raged in the deepest strata of the mind, and was not brought to an end by rapid sublimation and identification, is now carried on in a higher region, like the Battle of the Huns which in Kaulbach's painting is being fought out in the sky.

#### IV. THE TWO CLASSES OF INSTINCTS

WE have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already reached the conclusion that the ego is especially affected by perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time, the ego is subject to the influence of the instincts, too, like the id, of which it is in fact only a specially modified part.

I have lately developed a view of the instincts<sup>1</sup> which I shall here hold to and take as the basis of further discussions. According to this view we have to distinguish two classes of instincts, one of which, Eros or the sexual instincts, is by far the more conspicuous and accessible to study. It comprises not merely the uninhibited sexual instinct proper and the impulses of a sublimated or aim-inhibited nature derived from it, but also the self-preservative instinct, which must be assigned to the ego and which at the beginning of our analytic work we had good reason for setting in opposition to the sexual object-instincts. The second class of instincts was not so easy to define; in the end we came to recognize sadism as its representative. As a result of theoretical considerations, supported by biology, we assumed the existence of a death-instinct, the task of which is to lead organic matter back into the

<sup>1</sup> *Beyond the Pleasure Principle*, p. 639 above.

inorganic state; on the other hand, we supposed that Eros aims at complicating life by bringing about a more and more far-reaching coalescence of the particles into which living matter has been dispersed, thus, of course, aiming at the maintenance of life. Acting in this way, both the instincts would be conservative in the strictest sense of the word, since both would be endeavouring to re-establish a state of things that was disturbed by the emergence of life. The appearance of life would thus be regarded as the cause of the continuance of life and also as the cause of the striving towards death; and life itself would be a conflict and compromise between these two trends. The problem of the origin of life would remain a cosmological one; and the problem of the purpose and goal of life would be answered dualistically.

On this view a special physiological process (of anabolism or katabolism) would be associated with each of the two classes of instincts; both instincts would be active in every particle of living substance, although in unequal proportions, so that some one substance might be the principal representative of Eros.

This hypothesis throws no light whatever upon the manner in which the two classes of instincts are fused, blended, and mingled with each other; but that this takes place regularly and very extensively is an assumption indispensable to our conception. It appears that, as a result of the combination of unicellular organisms into multicellular forms of life, the death-instinct of the single cell can successfully be neutralized and the destructive impulses be diverted towards the external world through the instrumentality of a special organ. This special organ would seem to be the musculature; and the death-instinct would thus seem to express itself—though probably only in part—as an instinct of destruction directed against the external world and other living organisms.

Once we have admitted the conception of a fusion of the two classes of instincts with each other, the possibility of a—more or less complete—*defusion* of them forces itself upon us. The sadistic component of the sexual instinct would be a classical example of instinctual fusion serving a useful purpose; and the perversion in which sadism has made itself independent would be typical of defusion, though not of absolutely complete defusion. From this point we obtain a new view of a great array of facts which have not before been considered in this light. We perceive that, for purposes of discharge, the instinct of destruction is habitu-

ally enlisted in the service of Eros; we suspect that the epileptic fit is a product and sign of instinctual defusion; and we come to understand that defusion and the marked emergence of the death-instinct are among the most noteworthy effects of many severe neuroses, e.g., the obsessional neuroses. Making a swift generalization, we might conjecture that the essence of a regression of libido, e.g., from the genital to the sadistic-anal level, would lie in a defusion of instincts, just as, conversely, the advance from an earlier to the definitive genital phase would be conditioned by an accession of erotic components. The question also arises whether ordinary ambivalence, which is so often unusually strong in the constitutional disposition to neurosis, should not be regarded as the product of a defusion; ambivalence, however, is such a fundamental phenomenon that it more probably represents a state of incomplete fusion.

It is natural that we should now turn with interest to inquire whether there may not be instructive connections to be traced between the formations we have assumed to exist in the mind—the ego, the super-ego, and the id—and the two classes of instincts; and, further, whether the pleasure-principle which dominates mental processes can be shown to have any constant relation both to the two classes of instincts and to these differentiations which we have drawn within the mind. But before we discuss this, we must clear away a doubt which arises concerning the terms of the problem itself. There can be no doubt about the pleasure-principle, and the differentiations within the ego have good clinical justification, but the distinction between the two classes of instincts does not seem sufficiently assured and it is possible that facts of clinical analysis may be found to conflict with it.

One such fact appears to exist. Instead of the opposition between the two classes of instincts let us consider the polarity of love and hate. (There is no difficulty in finding a representative of Eros; but we must be grateful that we can find a representative of the elusive death-instinct in the instinct of destruction, for which hate points the way.) Now, clinical observation shows not only that love is with unexpected regularity accompanied by hate (ambivalence), and not only that in human relationships hate is frequently a forerunner of love, but also that in many circumstances hate changes into love and love into hate. If this change is anything more than a mere succession

in time, then clearly the ground is cut away from under a distinction so fundamental as that between erotic instincts and death-instincts, one which presupposes the existence of physiological processes running counter to each other.

Now the case in which someone first loves and then hates the same person (or the reverse), because that person has given him cause for doing so, has obviously nothing to do with our problem. Nor has the other case in which feelings of love that have not yet become manifest express themselves, to begin with, by enmity and aggressive tendencies; for it may be that here the destructive components in the object-cathexis have outstripped the erotic and are only later on joined by the latter. But we know of several instances in the psychology of the neuroses in which there are better grounds for assuming that a transformation does take place. In persecutory paranoia, the sufferer takes a particular way of defending himself against an unduly strong homosexual attachment to a given person, with the result that the person he once loved most is changed into a persecutor and then becomes the object of aggressive and often dangerous impulses on the part of the patient. Here we have grounds for interposing an intermediate phase in which the love is transformed into hate. Analytic investigation has only lately revealed that the sources of homosexuality and of desexualized social feelings include very intense feelings of rivalry giving rise to aggressive desires, which, after they have been surmounted, are succeeded by love for the object that was formerly hated or by an identification with it. The question arises whether in these instances we are to assume a direct transformation of hate into love. It is clear that here the changes are purely internal and an alteration in the behaviour of the object plays no part in them.

There is another possible mechanism, however, which we have come to know of by analytic investigation of the processes concerned in the change in paranoia. An ambivalent attitude is present from the outset and the transformation is effected by means of a reactive shifting of cathexis, by which energy is withdrawn from the erotic impulses and used to supplement the hostile energy.

Not quite the same thing but something like it happens when a hostile attitude of rivalry is overcome and leads to homosexuality. The hostile attitude has no prospect of gratification; consequently—i.e., as an economic measure—it is replaced by a loving attitude for which

there is more hope of satisfaction, that is, possibility of discharge. So we see that we are not obliged in either of these cases to assume a direct transformation of hate into love which would be incompatible with a qualitative distinction between the two classes of instincts.

It appears, however, that by including in our calculations this other mechanism by means of which love can be changed into hate, we have tacitly made another assumption which deserves to be formulated explicitly. We have reckoned as though there existed in the mind—whether in the ego or in the id—a displaceable energy, which is in itself neutral, but is able to join forces either with an erotic or with a destructive impulse, differing qualitatively as they do, and augment its total cathexis. Without assuming the existence of a displaceable energy of this kind, we can make no headway. The only question is where it comes from, what it belongs to, and what it signifies.

The problem of the quality of instinctual impulses and of its persistence throughout their vicissitudes is still very obscure and has hardly been attacked up to the present. In the sexual component-instincts, which are especially accessible to observation, it is possible to perceive the working of processes which are in the same category as what we are discussing; e.g., we see that some degree of communication exists between the component instincts, that an instinct deriving from one particular erotogenic source can make over its intensity to reinforce another component-instinct originating in another source, that gratification of one instinct can take the place of gratification of another, and many more facts of the same nature—all of which must encourage us to venture upon certain assumptions.

In the present discussion, moreover, I am putting forward nothing but a supposition; I have no proof to offer. It seems a plausible view that this neutral displaceable energy, which is probably active alike in the ego and in the id, proceeds from the narcissistic reservoir of libido, i.e., that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure-principle to obviate accumulations and to facilitate discharge. It is clear, incidentally, that there is a certain indifference about the path along which the discharge takes place, so long as it takes place somehow. We

know this trait; it is characteristic of the cathetic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transferences arising in analysis, which develop inevitably no matter who the analyst may be. Rank has recently published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. The penalty must be exacted even if it does not fall upon the guilty. It was in studying dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would seem to be characteristic of the ego to be more particular both about the choice of an object and about the path of discharge.

If this displaceable energy is desexualized libido, it might also be described as sublimated energy; for it would still retain the main purpose of Eros—that of uniting and binding—in so far as it helped towards establishing that unity, or tendency to unity, which is particularly characteristic of the ego. If the intellectual processes in the wider sense are to be classed among these displacements, then the energy for the work of thought itself must be supplied from sublimated erotic sources.

Here we arrive again at the possibility, which has already been discussed, that sublimation may take place regularly through the mediation of the ego. The other case will be recollected, in which the ego deals with the first object-cathexes of the id (and certainly with later ones too) by taking over the libido from them into itself and binding it to the ego-modification produced by means of identification. The transformation of erotic libido into ego-libido of course involves an abandonment of sexual aims, a desexualization. In any case this throws light upon an important function of the ego in its relation to Eros. By thus obtaining possession of the libido from the object-cathexes, setting itself up as sole love-object, and desexualizing or sublimating the libido of the id, the ego is working in opposition to the purposes of Eros and placing itself at the service of the oppos-

ing instinctual trends. It has to acquiesce in some of the other object-cathexes of the id; it has to go hand in hand with them, so to speak. We shall come back later to another possible consequence of this activity of the ego.

This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or far from robust. Part of this libido is sent out by the id into erotic object-cathexes, whereupon the ego, now growing stronger, attempts to obtain possession of this object-libido and to force itself upon the id as a love-object. The narcissism of the ego is thus seen to be secondary, acquired by the withdrawal of the libido from objects.

Over and over again we find on tracing instinctual impulses back that they disclose themselves as derivatives of Eros. If it were not for the considerations put forward in *Beyond the Pleasure Principle*, and ultimately for the sadistic constituents which have attached themselves to Eros, we should have difficulty in holding to our fundamental dualistic point of view. But since we cannot escape that view, we are driven to conclude that the death-instincts are by their nature mute, and that the clamour of life proceeds for the most part from Eros.<sup>1</sup>

And from the struggle against Eros! It can hardly be doubted that the pleasure-principle serves the id as a compass in its struggle against the libido—the force that introduces such disturbances into the process of life. If it is true that life is governed by Fechner's principle of constant equilibrium, it consists of a continuous descent towards death; but the falling of the level is delayed, and fresh tensions are introduced, by the claims of Eros, of the sexual instincts, as expressed in instinctual needs. The id, guided by the pleasure-principle, that is, by the perception of "pain," guards itself against these tensions in various ways. It does so in the first place by complying as swiftly as possible with the demands of the non-desexualized libido, i.e., by striving for the gratification of the directly sexual trends. But it does so further, and in a far more comprehensive fashion, in relation to one particular form of gratification which subsumes all component claims—that is, by discharge of the sexual substances, which are saturated conductors, so to speak, of the erotic tensions. The ejection of sexual sub-

<sup>1</sup> In fact, according to our view it is through the agency of Eros that the destructive instincts that are directed towards the external world have been diverted from the self.

stances in the sexual act corresponds in a certain degree with the separation of soma and germ-plasm. This accounts for the likeness between dying and the condition that follows complete sexual satisfaction, and for the fact that death coincides with the act of copulation in some of the lower animals. These creatures die in the act of reproduction because, after Eros has been eliminated through the process of gratification, the death-instinct has a free hand for accomplishing its purposes. Finally, as we have seen, the ego, by sublimating some of the libido for itself and its purposes, assists the id in its work of mastering the tensions.

## V. THE SUBORDINATE RELATIONSHIPS OF THE EGO

THE complexity of our subject-matter must be an excuse for the fact that none of the chapter-headings of this book correspond entirely to their contents, and that, in turning to new aspects of the problem, we constantly hark back to matters that have already been dealt with.

As has been said repeatedly, the ego is formed to a great extent out of identifications taking the place of cathexes, on the part of the id, which have been abandoned; the earliest of these identifications always fulfil a special office in the ego and stand apart from the rest of the ego in the form of a super-ego, while later on, as it grows stronger, the ego may become more able to withstand the effects of identifications. The super-ego owes its special position in the ego, or in regard to the ego, to a factor which must be considered from two sides: to the fact that on the one hand it was the first identification and one which took place while the ego was still feeble, and that on the other hand it was the heir to the Oedipus complex and thus incorporated into the ego objects of far greater significance than any others. The super-ego's relation to the subsequent modifications effected in the ego is roughly that of the primary sexual period in childhood to full-grown sexual activity after puberty. Although it is amenable to every later influence, it preserves throughout life the character given to it by its derivation from the father-complex, namely, the capacity to stand apart from the ego and to rule it. It is a memorial of the former weakness and dependence of the ego, and the mature ego remains subject to its domination. As the child was once compelled to obey

its parents, so the ego submits to the categorical imperative pronounced by its super-ego.

The descent of the super-ego from the first object-cathexes of the id, from the Oedipus complex, however, signifies even more for it. This descent, as we have already described, connects it with the phylogenetic acquisitions of the id and makes it a reincarnation of former ego-structures which have left their precipitates behind in the id. Thus the super-ego is always in close touch with the id and can act as its representative in relation to the ego. It reaches deep down into the id and is for that reason farther from consciousness than the ego.<sup>1</sup>

We can best appreciate these relations by turning our attention to certain clinical facts, which have long since lost their novelty but which still await theoretical discussion.

There are certain people who behave in a quite peculiar fashion during the work of analysis. When one speaks hopefully to them or expresses satisfaction with the progress of the treatment, they show signs of discontent and their condition invariably becomes worse. One begins by regarding this as defiance and as an attempt to prove their superiority to the physician, but later one comes to take a deeper and truer view. One becomes convinced, not only that such people cannot endure any praise or appreciation, but that they react inversely to the progress of the treatment. Every partial solution that ought to result, and in other people does result, in an improvement or a temporary suspension of symptoms produces in them for the time being an exacerbation of their illness; they get worse during the treatment instead of getting better. They exhibit the so-called *negative therapeutic reaction*.

There is no doubt that there is something in these people that sets itself against their recovery and dreads its approach as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for health. If we analyse this resistance in the usual way—then, even after we have subtracted from it the defiant attitude towards the physician and the fixation on the various kinds of advantage which the patient derives from the illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful even than such fam-

<sup>1</sup> It may be said that the psycho-analytical or meta-psychological ego stands on its head no less than the anatomical ego—the *cortical homunculus*.

iliar ones as narcissistic inaccessibility, the assumption of a negative attitude towards the physician, or a clinging to the advantages of the illness.

In the end we come to see that we are dealing with what may be called a "moral" factor, a sense of guilt, which is finding atonement in the illness and is refusing to give up the penalty of suffering. We are justified in regarding this rather disheartening explanation as conclusive. But, as far as the patient is concerned, this sense of guilt is dumb; it does not tell him he is guilty; he does not feel guilty, he simply feels ill. This sense of guilt expresses itself only as a resistance to recovery which it is extremely difficult to overcome. It is also particularly difficult to convince the patient that this motive lies behind his continuing to be ill; he holds fast to the more obvious explanation that treatment by analysis is not the right remedy for his case.<sup>1</sup>

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego-ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

<sup>1</sup> The battle with the obstacle of an unconscious sense of guilt is not made easy for the analyst. Nothing can be done against it directly, and nothing indirectly but the slow procedure of unmasking its unconscious repressed roots, and of thus gradually changing it into a conscious sense of guilt. One has a special opportunity for influencing it when this *Ucs* sense of guilt is a "borrowed" one, i.e., when it is the product of an identification with some other person who was once the object of an erotic cathexis. When the sense of guilt has been adopted in this way, it is often the sole remaining trace of the abandoned love-relation and not at all easy to recognize as such. (The likeness between this process and what happens in melancholia is unmistakable.) If one can unmask this former object-cathexis behind the *Ucs* sense of guilt, the therapeutic success is often brilliant, but otherwise the outcome of one's efforts is by no means certain. It depends principally on the intensity of the sense of guilt; there is often no counteracting force of similar strength which the treatment can put in motion against it. Perhaps it may depend, too, on whether the personality of the analyst allows of the patient's putting him in the place of his ego-ideal, and this involves a temptation for the analyst to play the part of prophet, saviour, and redeemer to the patient. Since the rules of analysis are diametrically opposed to the physician's making use of his personality in any such manner, it must be honestly confessed that here we have another limitation to the effectiveness of analysis; after all, analysis does not set out to abolish the possibility of morbid reactions, but to give the patient's ego *freedom* to choose one way or the other.

An explanation of the normal conscious sense of guilt (conscience) presents no difficulties; it is due to tension between the ego and the ego-ideal and is the expression of a condemnation of the ego pronounced by its criticizing function. The feelings of inferiority so well known in neurotics are presumably closely related to it. In two very familiar maladies, the sense of guilt is over-strongly conscious; in them the ego-ideal displays particular severity and often rages against the ego with the utmost cruelty. The attitude of the ego-ideal in these two diseases, the obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.

In certain forms of the obsessional neurosis the sense of guilt expresses itself loudly but cannot justify itself to the ego. Consequently the patient's ego rebels against this imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis shows that the super-ego is being influenced by processes that have remained hidden from the ego. It is possible to discover the repressed impulses which really occasion the sense of guilt. The super-ego is thus proved to have known more than the ego about the unconscious id.

In melancholia, the impression that the super-ego has obtained a hold upon consciousness is even stronger. But in this case the ego ventures no objection; it admits the guilt and submits to the punishment. The explanation of this difference is plain. In the obsessional neurosis, the reprehensible impulses which are being criticized by the super-ego have never formed part of the ego; while in melancholia, the object of the super-ego's wrath has become part of the ego through identification.

It is certainly not clear why the sense of guilt reaches such an extraordinary intensity in these two neurotic disorders; and indeed, the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases—in which the sense of guilt remains unconscious.

It is essentially in hysteria and in states of an hysterical type that this condition is found. The mechanism by which the sense of guilt is kept unconscious is easy to discover. The hysterical type of ego defends itself from the painful perception which the criticisms of its super-ego threaten to produce in it by the same means that it uses to defend itself from an

unendurable object-cathexis—by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that, as a rule, the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In the obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego contents itself with keeping at a distance the material to which the sense of guilt refers.

One may go further and venture the hypothesis that a great part of the sense of guilt must normally remain unconscious, because the origin of conscience is closely connected with the Oedipus complex which belongs to the unconscious. If any one were inclined to put forward the paradoxical proposition that the normal man is not only far more immoral than he believes but also far more moral than he has any idea of, psycho-analysis, which is responsible for the first half of the assertion, would have no objection to raise against the second half.<sup>1</sup>

It was a surprise to find that exacerbation of this *Ucs* sense of guilt could turn people into criminals. But it is undoubtedly a fact. In many criminals, especially youthful ones, it is possible to detect a very powerful sense of guilt which existed before the crime, and is not therefore the result of it but its motive. It is as if it had been a relief to be able to fasten this unconscious sense of guilt on to something real and immediate.

In all these situations, the super-ego displays its independence of the conscious ego and the closeness of its relations with the unconscious id. And now, having regard to the importance we ascribed to preconscious verbal residues in the ego, the question arises whether the super-ego, if it is in part unconscious, can consist in such verbal images, or, if not, in what it does consist. Our answer, though it does not carry us very far, will be that it cannot possibly be disputed that the super-ego, no less than the ego, is derived from auditory impressions; it is part of the ego and remains to a great extent accessible to consciousness by way of these verbal images (concepts, abstractions), but the cathectic energy of these elements of the super-ego does not originate from the auditory

perceptions, instruction, reading, etc., but from sources in the id.

The question which we postponed answering runs thus: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism—for the sense of guilt is the perception in the ego which corresponds to the criticism) and at the same time develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless fury, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death-instinct, and in fact it often enough succeeds in driving the ego into death, if the latter does not protect itself from the tyrant in time by a revulsion into mania.

The reproaches of conscience in certain forms of obsessional neurosis are just as painful and tormenting, but here the situation is less perspicuous. It is remarkable that the obsessional neurotic, in contrast to the melancholiac, never takes the step of self-destruction; he is as if immune against the danger of suicide, and is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In the obsessional neurosis it has become possible, through a regression to the pre-genital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it aims at destroying the object, or at least it appears to have this aim. These tendencies have not been adopted by the ego; it struggles against them with reaction-formations and precautionary measures, and they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows by its zeal in chastising these destructive intentions that they are no mere semblance evoked by regression, but an actual substitution of hate for love. Helpless in either direction, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome

<sup>1</sup> This proposition is only apparently a paradox; it simply states that human nature has a far greater capacity, both for good and for evil, than it thinks it has, i.e., than it is aware of through the conscious perceptions of the ego.

is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

The activity of the dangerous death-instincts within the individual organism is dealt with in various ways; in part they are rendered harmless by being fused with erotic components, in part they are diverted towards the external world in the form of aggression, while for the most part they undoubtedly continue their inner work unhindered. How is it then that in melancholia the super-ego can become a kind of gathering-place for the death-instincts?

From the point of view of morality, the control and restriction of instinct, it may be said of the id that it is totally non-moral, of the ego that it strives to be moral, and of the super-ego that it can be hyper-moral and then becomes as ruthless as only the id can be. It is remarkable that the more a man checks his aggressive tendencies towards others the more tyrannical, that is aggressive, he becomes in his ego-ideal. The ordinary view sees the situation the other way round: the standard set up by the ego-ideal seems to be the motive for the suppression of aggressiveness. The fact remains, however, as we have stated it: the more a man controls his aggressiveness, the more intense become the aggressive tendencies of his ego-ideal against his ego. It is like a displacement, a turning round upon the self. But even ordinary normal morality has a harshly restraining, cruelly prohibiting quality. It is from this, indeed, that the conception arises of an inexorable higher being who metes out punishment.

I cannot go further in my consideration of these questions without introducing a fresh assumption. The super-ego arises, as we know, from an identification with the father regarded as a model. Every such identification is in the nature of a desexualization or even of a sublimation. It now seems as though when a transformation of this kind takes place there occurs at the same time an instinctual defusion. After sublimation, the erotic component no longer has the power to bind the whole of the destructive elements that were previously combined with it, and these are released in the form of inclinations to aggression and destruction. This defusion would be the source of the general character of harshness and cruelty exhibited by the ideal—its dictatorial "Thou shalt."

Let us again consider the obsessional neurosis for a moment. The state of affairs is

different here. The defusion of love into aggressiveness has not been effected by the agency of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its tyranny over the innocent ego. It would seem, however, that in this case no less than in that of melancholia, the ego, having gained possession of the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which had before been mixed with the libido.

Our ideas about the ego are beginning to clear, and its various relationships are gaining distinctness. We now see the ego in its strength and in its weaknesses. It is entrusted with important functions. By virtue of its relation to the perceptual system, it arranges the processes of the mind in a temporal order and tests their correspondence with reality. By interposing the process of thinking it secures a postponement of motor discharges and controls the avenues to motility. This last office is, to be sure, a question more of form than of fact, in the matter of action the ego's position is like that of a constitutional monarch, without whose sanction no law can be passed but who hesitates long before imposing a veto on any measure put forward by Parliament. All the experiences of life that originate from without enrich the ego; the id, however, is another outer world to it, which it strives to bring into subjection to itself. It withdraws libido from the id and transforms the object-cathexes of the id into ego-constructions. With the aid of the super-ego, though in a manner that is still obscure to us, it draws upon the experiences of past ages stored in the id.

There are two paths by which the contents of the id can penetrate into the ego. The one is direct, the other leads by way of the ego-ideal; which of these two paths they take may, for many mental activities, be of decisive importance. The ego develops from perceiving instincts to controlling them, from obeying instincts to curbing them. In this achievement a large share is taken by the ego-ideal, which, indeed, is partly a reaction-formation against the instinctual processes in the id. Psychoanalysis is an instrument to enable the ego to push its conquest of the id further still.

From the other point of view, however, we see this same ego as a poor creature owing service to three masters and consequently menaced by three several dangers: from the

external world, from the libido of the id, and from the severity of the super-ego. Three kinds of anxiety correspond to these three dangers, since anxiety is the expression of a recoil from danger. Like the dweller in a borderland that it is, the ego tries to mediate between the world and the id, to make the id comply with the world's demands and, by means of muscular activity, to accommodate the world to the id's desires. In point of fact, it behaves like the physician during treatment by analysis; it offers itself to the id as a libidinal object in view of its power of adaptation to the real world, and aims at attaching the id's libido to itself. It is not only the ally of the id; it is also a submissive slave who courts the love of his master. Whenever possible, it tries to remain on good terms with the id; it draws the veil of its *Pcs* rationalizations over the id's *Ucs* demands; it pretends that the id is showing obedience to the mandates of reality, even when in fact it is remaining obdurate and immovable; it throws a disguise over the id's conflicts with reality and, if possible, over its conflicts with the super-ego too. Its position midway between the id and reality tempts it only too often to become sycophantic, opportunist, and false, like a politician who sees the truth but wants to keep his place in popular favour.

Towards the two classes of instincts the ego's attitude is not impartial. Its work of identification and sublimation gives the death-instincts in the id assistance in mastering the libido, but in so doing it incurs the risk of itself becoming the object of the death-instincts and of perishing. In order to be able to help in this way, it has to become flooded with libido itself; it thus becomes the representative of Eros and thenceforward desires to live and to be loved.

But since the ego's work of sublimation results in a defusion of the instincts and a liberation of the aggressive instincts in the super-ego, its struggle against the libido exposes it to the danger of maltreatment and death. In suffering under the attacks of the super-ego or perhaps even succumbing to them, the ego is meeting with a fate like that of the protozoa which are destroyed by the products of disintegration that they themselves have created. From the economic point of view, the morality that functions in the super-ego seems to be a similar product of disintegration.

Among the subordinate relationships in which the ego stands, that to the super-ego is perhaps the most interesting.

The ego is the true abode of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the equally dreaded process in the id, and discharging it as anxiety. This primitive reaction is later replaced by the introduction of protective cathexes (the mechanism of the phobias). What it is that the ego fears either from an external or from a libidinal danger cannot be specified; we know that it is in the nature of an overthrow or of extinction, but it is not determined by analysis. The ego is simply obeying the warning of the pleasure-principle. On the other hand, we can tell what lies hidden behind the ego's dread of the super-ego, its fear of conscience. The higher being which later became the ego-ideal once threatened the ego with castration, and this dread of castration is probably the kernel round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

The high-sounding phrase, "Every fear is ultimately the fear of death," has hardly any meaning; at any rate, it cannot be justified. It seems to me, on the contrary, perfectly correct to distinguish the fear of death from dread of an external object (objective anxiety) and from neurotic libidinal anxiety. It presents a difficult problem to psycho-analysis, for death is an abstract concept with a negative content for which no unconscious correlative can be found. It would seem that the mechanism of the fear of death can only be that the ego relinquishes its narcissistic libidinal cathexis in a very large measure, that is, that it gives up itself, just as it gives up some *external* object in other cases in which it feels anxiety. I believe that the fear of death concerns an interplay between the ego and the super-ego.

We know that the fear of death makes its appearance under two conditions (which, moreover, are entirely analogous to the other situations in which anxiety develops), namely, as a reaction to an external danger and as an internal process, as for instance in melancholia. Once again a neurotic manifestation may help us to understand a normal one.

The fear of death in melancholia only admits of one explanation: that the ego gives itself up because it feels itself hated and persecuted by the super-ego, instead of loved. To the ego, therefore, living means the same as being loved—being loved by the super-ego, which here again appears as the representative of the id. The super-ego fulfils the same function of pro-

protecting and saving that was fulfilled in earlier days by the father and later by Providence or destiny. But, when the ego finds itself in overwhelming danger of a real order which it believes itself unable to overcome by its own strength, it is bound to draw the same conclusion. It sees itself deserted by all the forces of protection and lets itself die. Here, moreover, is once again the same situation as that which underlay the first great anxiety-state of birth and the infantile anxiety of longing for an absent person—the anxiety of separation from the protecting mother.

These considerations enable us to conceive of the fear of death, like the fear of conscience, as a development of the fear of castration. The great significance which the sense of guilt has in the neuroses makes it conceivable that

ordinary neurotic anxiety is reinforced in severe cases by a development of anxiety between the ego and the super-ego (fear of castration, of conscience, of death).

The id, to which we finally come back, has no means of showing the ego either love or hate. It cannot say what it wants; it has achieved no unity of will. Eros and the death-instinct struggle within it; we have seen with what weapons the one group of instincts defends itself against the other. It would be possible to picture the id as under the domination of the mute but powerful death-instincts, which desire to be at peace and (as the pleasure-principle demands) to put Eros, the intruder, to rest; but that would be to run the risk of valuing too cheaply the part played by Eros.

# Inhibitions, Symptoms, and Anxiety

## CHAPTER I

IN describing pathological phenomena, we are enabled by the ordinary usages of speech to distinguish symptoms from inhibitions, without, however, attaching much importance to the distinction. Indeed, we might hardly think it worthwhile to differentiate more exactly between the two, were it not for the fact that we meet with illnesses in which we observe the presence of inhibitions but not of symptoms and are curious to know the reason for this.

The two concepts are not upon the same plane. Inhibition has a special relation to function. It does not necessarily have a pathological implication. One can quite well call a normal restriction of a function an inhibition of it. A symptom, on the other hand, actually denotes the presence of some pathological process. Thus, an inhibition (among other things) may be a symptom. In ordinary speech, we should use the word *inhibition* when there is a simple lowering of function, and *symptom* when a function has undergone some unusual change or when a new phenomenon has arisen out of it. Very often it seems to be quite an arbitrary matter whether we emphasize the positive side of a pathological process and call its consequences a *symptom*, or its negative side and call them an *inhibition*. But all this is really of little interest; and the problem as we have stated it does not carry us very far.

Since the concept of inhibition is so intimately associated with that of function, we may perhaps proceed to examine the various functions of the ego with a view to discovering what forms any disturbance of those functions will assume in each of the different neurotic affections. Let us pick out for a comparative study of this kind the sexual function and those of eating, of locomotion, and of occupational work.

(a) The sexual function is liable to a great number of disturbances, most of which exhibit the characteristics of simple inhibitions. These are classed together as *psychical impotence*. The normal performance of the sexual function can only come about as the result of a very complicated process, and disturbances may ap-

pear at any point in it. In men the chief points at which inhibition occurs are shown by: a turning away of the libido at the very beginning of the process (psychological unpleasure<sup>1</sup>); an abridgment of the sexual act (*ejaculatio praecox*), an occurrence which might equally well be regarded as a symptom; an arrest of the act before it has reached its natural conclusion (absence of ejaculation); or a non-appearance of the psychological results (lack of pleasure in orgasm). Other disturbances arise from the sexual function becoming dependent on special conditions of a perverse or fetishistic nature.

That there is a relationship between inhibition and anxiety is pretty evident. Many inhibitions obviously represent a relinquishment of a function whose exercise would produce anxiety. Many women are openly afraid of the sexual function. We class this anxiety under hysteria, just as we do the defensive symptom of disgust which, arising originally as a deferred reaction to the experiencing of a passive sexual act, appears later whenever the *idea* of such an act is presented. Furthermore, many obsessional acts turn out to be measures of precaution and security against sexual experiences and are thus of a phobic character.

This is not very illuminating. We can only note that disturbances of the sexual function are brought about by a great variety of means. (1) The libido may simply be turned away (this seems most readily to produce what we regard as an inhibition pure and simple); (2) the function may be less well carried out; (3) it may be hampered by having conditions attached to it, or modified by being diverted to other aims; (4) it may be prevented by measures of security; (5) if it cannot be prevented from starting, it may be immediately interrupted by the appearance of anxiety; and (6), if it is nevertheless carried out, there may be a subsequent reaction of protest against it and an attempt to undo what has been done.

(b) The function of nutrition is most frequently disturbed by a disinclination to eat, brought about by a withdrawal of libido. An

<sup>1</sup> Throughout this work, *Unlust* has been translated by the constructed word "unpleasure," while reserving "pain" for the German *Schmerz*.—TR.

increase in the desire to eat is also a not uncommon thing. The compulsion to eat is attributed to a fear of starving; but this is a subject which has been but little studied. The hysterical defence against eating is known to us in the symptom of vomiting. Refusal to eat owing to anxiety is a concomitant of psychotic states (delusions of being poisoned).

(c) In many neurotic conditions, locomotion is inhibited by a disinclination to walk or a weakness in walking. In hysteria, there will be a paralysis of the motor apparatus, or this one special function of the apparatus will be abolished (abasia). Especially characteristic are the increased difficulties that appear in locomotion owing to the introduction of certain stipulations whose non-observance results in anxiety (phobia).

(d) In inhibition in work—a thing which we so often have to deal with as an isolated symptom in our therapeutic work—the subject feels a decrease in his pleasure in it or becomes less able to do it well; or he has certain reactions to it, like fatigue, giddiness, or sickness, if he is obliged to go on with it. If he is a hysteric he will have to give up his work, owing to the appearance of organic and functional impairments of activity which make it impossible for him to carry it on. If he is an obsessional neurotic, he will be perpetually being distracted from his work or losing time over it owing to delays and repetitions.

Our survey might be extended to other functions of the ego as well; but there would be nothing more to be learned by doing so, for we should not penetrate below the surface of the phenomena presented to us. Let us then proceed to describe inhibition in such a way as to leave very little doubt about what is meant by it, and say that inhibition is the *expression of a restriction of an ego-function*.

A restriction of this kind can itself have very different causes. Many of the mechanisms involved in a renunciation of function are well known to us, as is a certain general purpose which runs through it. This purpose is more easily recognizable in the specific inhibitions. Analysis shows that, when activities, like playing the piano, writing, or even walking, undergo neurotic inhibitions, it is because the physical organs brought into play—the fingers or the feet—have become too strongly eroticized. It has been discovered as a general fact that the ego-function of an organ is impaired if its erotogenicity—its sexual significance—is increased. It behaves, if I may be allowed a

somewhat vulgar analogy, like a maid-servant who refuses to go on cooking because her master has started a love-affair with her. As soon as writing, which entails making a liquid substance flow on to a piece of white paper, assumes the significance of copulation, or as soon as walking becomes a symbolic substitute for treading upon the body of mother earth, both writing and walking are stopped because they represent the performance of a forbidden sexual act. The ego renounces these functions, which are within its sphere, in order not to have to undertake fresh measures of repression—in order to avoid coming into conflict with the id.

There are clearly also inhibitions which serve the purpose of self-punishment. This is often the case in inhibitions of occupational activities. The ego is not allowed to carry on those activities, because they would bring success and gain, and these are things which the severe super-ego has forbidden. So the ego gives them up too, in order to avoid coming into conflict with the super-ego.

The more generalized inhibitions of the ego obey a different mechanism of a simple kind. When the ego is faced with a particularly difficult mental task, as occurs in mourning or when there is some tremendous suppression of affect or when a continual flood of sexual phantasies is being kept down, it loses so much of the energy at its disposal that it has to cut down the expenditure of it at many points at once. It is in the position of a speculator whose money has become tied up in various enterprises. I came across an instructive example of this kind of intense, though short-lived, general inhibition. The patient, an obsessional neurotic, used to be overcome by a paralysing fatigue which lasted for one or more days whenever something occurred which should obviously have thrown him into a rage. We have here a point of departure from which we may hope to reach an understanding of the condition of general inhibition which characterizes states of depression, including the gravest form of them, melancholia.

As regards inhibitions, then, we may say in conclusion that they are restrictions of the functions of the ego which have either been imposed as a measure of precaution or brought about as a result of an impoverishment of energy; and we can see without difficulty in what respect an inhibition differs from a symptom: for a symptom cannot be described as a process that takes place within, or acts upon, the ego.

## CHAPTER II

THE main characteristics of the formation of symptoms have long since been studied and, I hope, established beyond dispute. A symptom is a sign of, and a substitute for, an instinctual gratification which has remained in abeyance; it is a consequence of the process of repression. Repression proceeds from the ego when the latter—it may be at the behest of the super-ego—refuses to associate itself with an instinctual cathexis which has been aroused in the id. The ego is able by means of repression to keep the idea which is the vehicle of the reprehensible impulse from becoming conscious. Analysis shows that the idea often persists as an unconscious formation.

So far everything seems clear; but we soon come upon difficulties which have not as yet been solved. Up till now our account of what occurs in repression has laid great stress on this point of exclusion from consciousness. But it has left other points open to uncertainty. One question that arose was: what happened to the instinctual impulse which had been actuated in the id and which sought to be gratified? The answer was an indirect one. It was that, owing to the process of repression, the pleasure that would have been expected from gratification had been transformed into unpleasure. But we were then faced with the problem of how the gratification of an instinct could produce unpleasure. The whole matter can be clarified, I think, if we commit ourselves to the definite statement that, as a result of repression, the intended course of the excitatory process in the id does not occur at all; the ego succeeds in inhibiting or deflecting it. If this is so the problem of *transformation of affect* under repression disappears. At the same time, this view implies that the ego can exert a very extensive influence over processes in the id, and we shall have to find out in what way it is able to develop such astonishing powers.

It seems to me that the ego obtains this influence in virtue of its intimate connections with the perceptual system—connections which, as we know, constitute its essence and provide the basis of its differentiation from the id. In its function, the perceptual system, which we have called *Pcpt-Cs*, is bound up with the phenomenon of consciousness. It receives excitations not only from outside but from within and endeavours, by means of the pleasure-unpleasure sensations which reach it from these directions, to direct the course of every mental event in accordance with the pleasure-principle.

We are very apt to think of the ego as powerless against the id; but, when it is opposed to an instinctual process, it has only to give a *signal of unpleasure* in order to attain its object with the aid of that almost omnipotent institution, the pleasure-principle. To take this situation by itself for a moment, we can illustrate it by an example from another field. Let us imagine a country in which a certain small faction objects to a proposed measure the passage of which would have the support of the masses. This minority obtains command of the press and by its help manipulates the supreme arbiter, *public opinion*, and so succeeds in preventing the measure from being passed.

But this explanation opens up fresh problems. Whence does the energy come which is employed for giving the signal of unpleasure? Here we may be assisted by the idea that a defence against an unwelcome *internal* process will be modelled upon the defence adopted against an *external* stimulus, that the ego wards off internal and external dangers alike along identical lines. In the case of external danger, the organism has recourse to attempts at flight. The first thing it does is to withdraw cathexis from the perception of the dangerous object; later on it discovers that it is a better plan to perform muscular movements of such a sort as will render perception of the dangerous object impossible, even in the absence of any refusal to perceive it—that it is a better plan, that is, to remove itself from the sphere of danger. Repression is an equivalent of this attempt at flight. The ego withdraws its (pre-conscious) cathexis from the psychical representative of the impulse that is to be repressed and uses that cathexis for the purpose of releasing unpleasure (anxiety). The problem of how anxiety arises in connection with repression may be no simple one; but we may legitimately maintain the opinion that the ego is the actual seat of anxiety and give up our earlier view that the cathectic energy of a repressed impulse is automatically turned into anxiety. If I expressed myself in the latter sense on former occasions, I was giving a phenomenological description and not a metapsychological explanation of what was occurring.

This brings us to a further question: how is it possible, from an economic point of view, for a mere process of withdrawal and discharge, like the withdrawing of a pre-conscious ego-cathexis, to produce unpleasure or anxiety, seeing that, according to our assumptions, unpleasure and anxiety can only arise as a result

of an *increase* in cathexis? The reply is that this causal sequence should not be explained from an economic point of view. In repression, anxiety is not newly created; it is reproduced as an affective state on the model of an already existing memory picture. If we go further and enquire into the origin of that anxiety—and of affects in general—we shall be leaving the realm of pure psychology and entering the confines of physiology. Affective states have become incorporated in the mind as precipitates of primeval traumatic experiences, and when a similar situation occurs they are revived in the form of memory symbols. I do not think I have been wrong in likening them to the more recent and individually acquired hysterical attack and in regarding them as normal prototypes of it. In man and the higher animals it would seem that the act of birth, as the individual's first experience of anxiety, has given the affect of anxiety certain characteristic forms of expression. But, while acknowledging this connection, we must not lay undue stress on it nor overlook the fact that biological necessity demands that a situation of danger should have an affective symbol, so that a symbol of this kind would have to be created in any case. Moreover, I do not think that we are justified in assuming that whenever there is an outbreak of anxiety something like a reproduction of the situation of birth goes on in the mind. It is not even certain whether hysterical attacks, though they were originally traumatic reproductions of this sort, permanently retain that character.

As I have shown elsewhere, most of the repressions with which we have to deal in our therapeutic work are cases of after-expulsion. They presuppose the operation of earlier, primal repressions which exert an attraction on the more recent situation. Far too little is known as yet about the background and preliminary stages of repression. There is a danger of over-estimating the part played in repression by the super-ego. We cannot at present say, for instance, whether it is the emergence of the super-ego which provides the line of demarcation between primal repression and after-expulsion. At any rate, the earliest outbreaks of anxiety, which are of a very intense kind, occur before the super-ego has become differentiated. It is highly probable that the precipitating causes of primal repression are quantitative factors such as an excessive degree of excitation and the breaking through of the protective barrier against stimuli.

This mention of the protective barrier sounds

a note which recalls to us the fact that repressions occur in two different situations, namely, when an undesirable instinctual impulse is aroused by some external perception, and when it arises internally without any such provocation. We shall return to this difference presently. But the protective barrier only exists in regard to external stimuli, not in regard to internal instinctual demands.

So long as we direct our attention to the ego's attempt at flight, we shall get no nearer to the subject of symptom-formation. A symptom arises from an instinctual impulse which has been prejudicially affected by repression. If the ego, by making use of the signal of unpleasure, attains its object of completely suppressing the instinctual impulse, we learn nothing of how this has happened. We can only find out about it from those cases in which repression has to a greater or less extent failed. In this event the position, generally speaking, is that the instinctual impulse has found a substitute in spite of repression, but a substitute which is very much reduced, displaced, and inhibited, and which is no longer recognizable as a gratification. And when the impulse is carried out, there is no sensation of pleasure; its carrying out has, instead, the quality of a compulsion.

In thus degrading a gratificatory process to a symptom, repression displays its power in a further respect. The substitutive process is prevented, if possible, from finding discharge through motility; and even if this cannot be done the process is forced to expend itself in making alterations in the subject's own body and is not permitted to impinge upon the outer world. It may not be transformed into action. For, as we know, in repression the ego is operating under the influence of external reality and therefore it debars the substitutive process from having any effect upon that reality.

Just as the ego controls the path to action in regard to the outer world, so it controls access to consciousness. In repression it displays its power in both directions, acting, in the one manner, upon the instinctual impulse itself and, in the other, upon the psychical representative of that impulse. At this point it is relevant to ask how I can reconcile this acknowledgment of the might of the ego with the description of its position which I gave in *The Ego and the Id*. In that book I drew a picture of its dependence upon the id and upon the super-ego which revealed how powerless and apprehensive it was in regard to both and with what an effort

it maintained its superiority over them. This view has been widely echoed in psycho-analytic literature. A great deal of stress has been laid on the weakness of the ego in relation to the id and of our rational elements in the face of the demonic forces within us; and there is a strong tendency to make what I have said into a foundation-stone of a psycho-analytic *Weltanschauung*. Yet surely the psycho-analyst, with his knowledge of the way in which repression works, should, of all people, be restrained from adopting such extreme and one-sided views.

I must confess that I am not at all partial to the fabrication of *Weltanschauungen*. Such activities may be left to philosophers, who avowedly find it impossible to make their journey through life without a Baedeker of that kind to tell them all about everything. Let us humbly accept the contempt with which they look down on us from the vantage-ground of their superior needs. But since we too cannot forego our narcissistic pride, we will draw comfort from the reflection that such "Guides to Life" soon grow out of date, and that it is precisely short-sighted, narrow, and finicky work like ours which obliges them to appear in new editions, and that even the most up-to-date of them are nothing but attempts to find a substitute for the ancient, useful, and all-embracing catechism. We know well enough how little light science has so far been able to throw on the problems that surround us. But however much ado the philosophers may make, they cannot alter the situation. Only patient, persevering research, in which everything is subordinated to the one requirement of certainty, can gradually bring about a change. The benighted traveller may sing aloud in the dark to deny his own fears; but, for all that, he will not see an inch further beyond his nose.

### CHAPTER III

To return to this problem about the ego. The apparent contradiction is due to our having taken abstractions too rigidly and attended exclusively now to the one side and now to the other of what is in reality a complicated state of affairs. We were justified, I think, in dividing the ego from the id, for there were certain considerations which necessitated that step. On the other hand, the ego is identical with the id, and is merely a specially differentiated part of it. If we regard this part by itself, in contradistinction to the whole, or if a real split has occurred between the two, the weakness of the

ego becomes apparent. But if the ego remains bound up with the id and indistinguishable from it, then it displays its power. The same is true of the relation between the ego and the super-ego. In many situations, the two are merged; and as a rule we can only distinguish one from the other when there is a tension or conflict between them. In repression, the decisive fact is that the ego is an organization and the id is not. The ego is, indeed, the organized portion of the id. We should be quite wrong in picturing the ego and the id as two opposing camps and in thinking that, when the ego tries to suppress a part of the id by means of repression, the remainder of the id comes to the rescue of the endangered part and measures its strength with the ego. This may often be what happens, but it is not the primary situation in repression. As a rule, the instinctual impulse which is to be repressed remains isolated. Although the act of repression demonstrates the strength of the ego, in one particular it reveals the ego's powerlessness and reveals, too, how impervious to influence are the separate instinctual impulses of the id. For the mental process, which has been turned into a symptom owing to repression, maintains its existence outside the organization of the ego and independently of it. Indeed, it is not the process alone but all its derivatives which enjoy, as it were, the privilege of extra-territoriality; and whenever they come into associative contact with a part of the ego-organization, it is not at all certain that they will not draw that part over to themselves and thus enlarge themselves at the expense of the ego. Long ago I compared a symptom to a foreign body which was keeping up a constant succession of stimuli and reactions in the tissue in which it was imbedded. It does sometimes happen that the defensive struggle against an unwelcome instinctual impulse is brought to an end with the formation of a symptom. As far as can be seen, this is most often possible in hysterical conversions. But usually the outcome is different. The initial act of repression is followed by tedious and often interminable manoeuvres in which the struggle against the instinctual impulse is prolonged into a struggle against the symptom.

In this secondary defensive struggle, the ego faces two ways. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based upon the maintenance of free intercourse and of

the possibility of reciprocal influence between all its parts. Its de-sexualized energy still shows traces of its origin in its tendency to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and foreign by using every possible method to bind them to itself in one way or another, and to incorporate them in its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for gratification and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while, on the other hand, they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-position with a mixed cathexis. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom—to this piece of the internal world which is alien to it—just as it normally does to the objective, external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of the capacities of the individual, and this can be exploited to appease some demand on the part of the super-ego or to refuse some requirement coming from the external world. In this way, the symptom gradually grows to be the representative of important interests; it is found to be useful for the maintenance of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of *healing* round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might thenceforward live

on his pension without having to work any more.

In obsessional neurosis and paranoia, the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic gratification which it would otherwise forgo. The symptoms which the obsessional neurotic constructs flatter his self-esteem by making him feel that he is better than others because he is specially cleanly or specially conscientious. The delusional constructions of the paranoiac offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.

All of this results in what is known as the *epinosic gain* of a neurosis. This epinosic gain comes to the assistance of the ego in its endeavour to incorporate the symptom and increases the fixation of the latter. When the analyst tries to help the ego in its struggle against the symptom, he finds that these reconciliatory bonds between ego and symptom operate on the side of the resistances and that they are not easy to loosen.

The two lines of behaviour which the ego adopts towards the symptom are in fact directly opposed to each other. For the other line is less friendly in character, since it continues in the direction of repression. Nevertheless the ego, it appears, cannot be accused of inconsistency. Being of a peaceable disposition it would like to incorporate the symptom in its framework. It is from the symptom itself that the trouble comes. For the symptom, being the true substitute and derivative of the repressed impulse, carries on the rôle of the latter; it continually renews its demands for gratification and thus obliges the ego in its turn to give the signal of unpleasure and put itself in a posture of defence.

The secondary defensive struggle against the symptom is many-sided. It is fought out on many fields and makes use of a multitude of means. We shall not be able to say much about it until we have made an enquiry into individual cases of symptom-formation. In doing this we shall have an opportunity of going into the problem of anxiety—a problem which has long been looming in the background. The wisest plan will be, I think, to start from the symptoms produced by the hysterical neuroses; for we are not as yet in a position to consider the conditions in which the symptoms of obsessional neurosis, paranoia, and other neuroses are formed.

## CHAPTER IV

LET us take as our first example an infantile hysterical phobia of animals. We will select the case of Little Hans,<sup>1</sup> whose phobia of horses was undoubtedly typical in all its main features. The first thing that is apparent is that in a concrete case of neurotic illness the state of affairs is much more complex than one would suppose so long as one was dealing with abstractions. It takes some time to orientate oneself and to decide which the repressed impulse is, what substitutive symptom it has found and where the motive for repression lies.

Little Hans refused to go out into the street because he was afraid of horses. This is the raw material of the case. Which part of it constitutes the symptoms? Is it his having the fear? Is it his choice of an object for his fear? Is it his giving up his freedom of movement? Or is it several of these combined? What is the gratification which he renounces? And why does he have to renounce it?

At a first glance one is tempted to reply that the case is not so very obscure. Little Hans's unaccountable fear of horses is the symptom, and his inability to go out into the streets is an inhibition, a restriction which his ego has imposed on itself so as not to arouse the anxiety-symptom. The second point is clearly correct; and in the discussion which follows I shall not concern myself any further with this inhibition. As regards what was presumably the symptom, a superficial acquaintance with the case does not even disclose its true formulation. For further investigation shows that what he was suffering from was not a vague fear of horses but a quite definite apprehension that a horse was going to bite him. This idea, indeed, was endeavouring to withdraw from consciousness and get itself replaced by an undefined phobia in which only the anxiety and its object still appeared. Was it perhaps this idea which was the nucleus of his symptom?

We shall not make any headway until we have reviewed the little boy's psychological situation as a whole as it came to light in the course of analytic treatment. He was at that time in the Oedipus position, with its attendant feelings of jealousy and hostility towards his father whom nevertheless—except in so far as his mother was the cause of estrangement—he dearly loved. Here, then, we have a conflict due to ambivalence: a firmly rooted love and a no less well grounded hatred directed against

one and the same person. Little Hans's phobia must be an attempt to solve this conflict. Conflicts of this kind due to ambivalence are very frequent and they can have another typical outcome, in which one of the two conflicting feelings (usually that of affection) becomes enormously enhanced and the other vanishes. Only the exaggerated degree and compulsive character of the feeling that remains betray the fact that it is not the sole one in existence but is continually on the alert to keep the opposite feeling under suppression, and enables us to postulate the operation of a process which we call *repression by means of reaction-formation* (in the ego). Cases like Little Hans's show no traces of a reaction-formation of this kind. There are clearly different ways of egress from a conflict of ambivalence.

Meanwhile we have been able to establish another point with certainty. The instinctual impulse which underwent repression in Little Hans was a hostile one against his father. Proof of this was obtained in his analysis while the idea of the biting horse was being followed up. Hans had seen a horse fall down and he had also seen a playmate, with whom he was playing at horses, fall down and hurt himself. Analysis justified the inference that he had a conative impulse that his father should fall down and hurt himself as his playmate and the horse had done. Moreover, his attitude towards someone's departure on a certain occasion makes it probable that his wish that his father should be out of the way found a less hesitating expression. But a wish of this sort is tantamount to an intention of putting the father out of the way oneself—is tantamount, that is, to the murderous impulse which is one component of the Oedipus complex.

So far there seem to be no connecting links between Little Hans's repressed instinctual impulse and the substitute for it which we suspect is to be seen in his phobia of horses. Let us simplify his psychological situation by setting on one side the elements of infancy and ambivalence. Let us imagine that he is a young servant who is in love with the mistress of the house and has received some tokens of her favour. He hates his master, who is more powerful than he, and he would like to have him out of the way. It would then be eminently natural for him to be afraid of his master and to dread his vengeance—just as Little Hans was frightened of horses. We cannot, therefore, describe the anxiety belonging to this phobia as a symptom. If Little Hans, being in love

<sup>1</sup> Freud, "Analysis of a Phobia in a Five-Year-Old Boy" (1909), *Collected Papers*, III.

with his mother, had shown fear of his father, we should have no right to say that he had a neurosis or a phobia. His emotional reaction would have been entirely comprehensible. What made it a neurosis was one thing alone: the replacement of his father by a horse. It is this displacement, then, which has a claim to be called a symptom, and which, incidentally, constitutes the alternative mechanism which enables a conflict due to ambivalence to be resolved without the aid of a reaction-formation. Such a displacement is made possible or facilitated at Little Hans's early age because the inborn traces of totemistic thought can still be easily revived. Children do not as yet recognize or, at any rate, lay such exaggerated stress upon the gulf that separates human beings from the animal world. In their eyes the grown man, the object of their fear and admiration, still belongs to the same category as the big animal who has so many enviable attributes but against whom they have been warned because he may become dangerous. As we see, the conflict of ambivalence is not dealt with in relation to one and the same person; it is circumvented, as it were, by one of the pair of conflicting impulses being directed to a vicarious figure.

So far everything is clear. But the analysis of Little Hans's phobia has been very disappointing in one respect. The distortion which constituted the symptom-formation was not applied to the psychical representative (the ideational content) of the instinctual impulse that was to be repressed; it was applied to a quite different representative and one which only corresponded to a *reaction* to the disagreeable instinct. It would be more in accordance with our expectations if Little Hans had developed, instead of a fear of horses, an inclination to ill-treat them and to beat them or if he had expressed in strong terms a wish to see them fall down or to be hurt or even die in agony ("make a row with their feet"). Something of the sort did in fact emerge in his analysis, but it was not by any means in the forefront of his neurosis. And, curiously enough, if he really had produced an animosity of this sort not against his father but against horses as his main symptom, we should not have said that he was suffering from a neurosis. There must be something amiss either with our view of repression or with our definition of a symptom. One thing strikes us at once: if Little Hans had really behaved in such a way to horses it would mean that repression had in

no way altered the character of his objectionable and aggressive impulses themselves but only the object against which they were directed.

Undoubtedly there are cases in which this is all that repression does. But more than this has happened in the development of Little Hans's phobia—how much more can be guessed from another analysis.

As we know, Little Hans alleged that what he was afraid of was that a horse would bite him. Now sometime later I was able to learn something about the origin of another animal phobia. In this instance the dreaded animal was a wolf; it, too, had the significance of a father-substitute.<sup>1</sup> As a boy the patient in question—a Russian whom I did not analyse until he had reached his thirties—had had a dream (whose meaning was revealed in analysis) and immediately after it had developed a fear of being eaten up by a wolf, like the seven little goats in the fairy tale. In the case of Little Hans, the ascertained fact that his father used to play at horses with him doubtless determined his choice of a horse as his anxiety-animal. In the same way it appeared at least highly probable that the father of my Russian patient used, when playing with him, to pretend to be a wolf and jokingly threaten to eat him up. Since then I have come across a third instance. The patient was a young American who came to me for treatment. True, he had not developed an actual animal phobia, but it was precisely because of this omission that his case helped to throw light upon the other two. As a child he had been sexually excited by a fantastic children's story which had been read aloud to him about an Arab chief who pursued a gingerbread man so as to eat him up. He identified himself with this edible person, and the Arab chief was easily recognizable as a father-substitute. This phantasy formed the substratum of his auto-erotic phantasies.

The idea of being devoured by the father is typical, age-old and common to all children. It has familiar parallels in mythology (the myth of Cronos) and in the animal kingdom. Yet in spite of this, such an idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to, and we cannot understand how it can have become the subject-matter of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being eaten by the father gives

<sup>1</sup> Freud, "From the History of an Infantile Neurosis" (1918), *Collected Papers*, III.

expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic way.

Further research into the case-history of the Wolf Man leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender inclination when it is expressed in the language belonging to that transition phase between the oral and sadistic organization of the libido which has been left behind. Besides, is it merely a question of the replacement of a particular psychical representative by a regressive form of expression, or is it a question of the genuine regressive degradation of a genitally orientated impulse in the id? It is not at all easy to make certain. The case-history of the Wolf Man gives very definite support to the second, more serious, view, for, from the time of the decisive dream onward, the boy became naughty, tormenting, and sadistic, and soon after developed a regular obsessional neurosis. At any rate we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it much more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it.

The case of the Wolf Man and the somewhat less complicated one of Little Hans raise a number of further considerations. But we already learn two unexpected facts. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by being reversed. Instead of aggressiveness *towards* the father there appeared aggressiveness *from* the father in the shape of revenge. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, a certain degree of degradation of it is all that is needed to reduce it to the oral stage. This stage, while only adumbrated in Little Hans's fear of being bitten, was blatantly exhibited in the Wolf Man's terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of a doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a loving, passive impulse directed towards the father, which had already attained the genital (phallic) level of libidinal organization. As regards the final outcome of

the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single current of instinctual repression, we have thus come upon a confluence of two. The two instinctual impulses that have been overtaken by repression—sadistic aggressiveness towards the father and passive affection for him—form a pair of opposites. Furthermore, a full comprehension of Little Hans's case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of it. The process of repression had attacked almost all the components of his Oedipus complex—both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient, this state of affairs was much less patent.

These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation and with that intention selected the earliest and, to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal—Little Hans and the Wolf Man—as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to Little Hans that we can positively assert that what his phobia disposed of were the two main impulses of the Oedipus complex, viz., his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it subsided after his phobia appeared. Hans seems, in fact, to have been a normal boy with what is called a *positive* Oedipus complex. It is possible that those factors which seem not to have been present were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Wolf Man something different is lacking. His attitude to female objects had been disturbed by an early seduction, and his passive,

feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that his passive tender attitude to his father had been overtaken by repression. In his case, too, the other factors may have been operative as well; but they were not visible. How is it that, whereas these differences between the two cases almost amount to an antithesis, the final outcome—a phobia—was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was identical in both. It was the fear of impending castration. Little Hans gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can easily be extended into meaning a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his desire to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals—of the organ which distinguished him from women. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, are broken down by the castration complex. The Russian boy's anxiety-idea of being eaten up by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

So now we have made the unexpected discovery that in both patients the motive force of the repression was a fear of castration. The ideational content of their anxiety—being bitten by a horse and being eaten up by a wolf—was a substitute by distortion for the idea of being castrated by their father. It was this idea which had undergone repression. In the Russian boy the idea was an expression of a desire which was not able to subsist in the face of his masculine revolt; in Little Hans it was the expression of a reaction in him which had

turned his aggressiveness into its opposite. But the *affect* of anxiety, which was the essence of their phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore an objective fear, a fear of a danger which actually was imminent or believed to be so. It was anxiety which produced repression, and not, as I formerly believed, repression which produced anxiety.

I cannot deny the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the psychical representative of the instinct is distorted, displaced, etc., while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion. The anxiety felt in animal phobias is the castration anxiety of the ego; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be a fear of incurring sexual temptation—a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had formerly been content to say that after the occurrence of repression there appeared, in place of the manifestation of libido that was to be expected, a certain amount of anxiety, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.

It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the actual neuroses, at a time when analysis was still a very long way from distinguishing between processes in the

ego and processes in the id. I found that out-breaks of anxiety and a general state of anxiety-preparedness were produced by certain sexual practices such as *coitus interruptus*, undischarged sexual excitement, or enforced abstinence—that is, whenever sexual excitement was inhibited, arrested, or deflected in its progress towards gratification. Since sexual excitement was an expression of libidinal instinctual impulses, it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to interruption at the instigation of repression. We can still maintain, therefore, that in repression anxiety is produced from the libidinal cathexes of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which is not at all simple to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitement interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. *Non liquet*.<sup>1</sup>

### CHAPTER V

WE set out to study the formation of symptoms and the secondary struggle waged by the ego against symptoms. But in picking on the phobias for this purpose we have clearly made an unlucky choice. The anxiety which predominates in them appears to complicate and obscure the picture. There are plenty of neuroses which exhibit no anxiety whatever. True conversion-hysteria is one of these. Even in its most severe symptoms no admixture of anxiety is found. This fact alone ought to warn us against making too close a connection between anxiety and symptom-formation. The phobias are so closely akin to conversion-hysteria in every other respect that I have felt justified in classing them with it under the name of *anxiety-hysteria*. But no one has as yet been able to say what it is that determines whether any given case shall take the form of a conversion-

hysteria or a phobia—has been able, that is to say, to establish how the production of anxiety in hysteria is conditioned.

The commonest symptoms of conversion-hysteria—motor paralyses, contractures, involuntary actions or discharges, pains, and hallucinations—are cathectic processes which are either permanently maintained or intermittent. But this puts fresh difficulties in the way. Not much is actually known about these symptoms. Analysis can show what the disturbed excitatory process is which the symptoms replace. It usually turns out that they themselves have a share in that process. It is as though they had concentrated in themselves the whole energy of the process. For instance, it will be found that the pains from which a patient suffers were present in the situation in which the repression occurred; or that his hallucination was, at that time, a perception; or that his motor paralysis stands for a defence against an action which he had meant to perform but which had been inhibited; or that his contracture is usually a displacement of an intended innervation of the muscles in some other part of his body; or that his convulsions are the equivalent of an outburst of affect which has been withdrawn from the normal control of the ego. The sensation of unpleasure which accompanies the appearance of the symptoms varies in a striking degree. In chronic symptoms which have been displaced on to motility, like paralyses and contractures, it is almost always entirely absent; the ego behaves towards the symptoms as though it had nothing to do with them. In intermittent symptoms and in those concerned with the sensory field, unpleasure is as a rule distinctly felt; and in symptoms of pain it may reach an extreme degree. The picture presented is so manifold that it is difficult to discover the factor which permits of all these variations and yet establishes a uniformity in them. There is, moreover, little to be seen in conversion-hysteria of the ego's struggle against the symptom after it has been formed. It is only when sensitivity to pain in some part of the body constitutes the symptom that that symptom is in a position to play a dual rôle. In that case the symptom of pain will appear no less regularly whenever the part of the body concerned is touched from outside than when the pathogenic situation which it represents is associatively activated from within; and the ego will take precautions to prevent the symptom from being aroused through external perceptions. Why the formation of symptoms in

<sup>1</sup> It is not clear.—Ed.

conversion-hysteria should be such a peculiarly obscure thing I do not know; but the fact provides us with a good reason for quitting such an unproductive field of enquiry.

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite bias. They are either prohibitions, precautions and expiations—that is, negative in character—or they are substitutive gratifications often appearing in symbolic disguise. The negative, defensive group of symptoms is the more primary of the two; but as the illness is prolonged the gratificatory group, overriding all defensive measures, gains the upper hand. The symptom-formation scores a triumph if it succeeds in combining the two by joining to what was originally a defensive command or prohibition the significance of a gratification; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthetization which it has already been seen to possess. In extreme cases the patient manages to make most of his symptoms have, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, no one knows why, plays such a large part in obsessional neuroses. In the crudest instance the symptom has two phases: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one, even if it does not go quite so far as to carry out its opposite.

Two impressions at once emerge from this brief survey of obsessional symptoms. The first is that a ceaseless struggle is being waged against the repressed, in which the repressing forces steadily lose ground; the second is that the ego and the super-ego have a specially large share in the formation of the symptoms.

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of warding off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a

very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be weak and insufficiently resistant, so that when the ego begins its defensive actions the first thing it succeeds in doing is to throw back, in part or altogether, the genital organization (of the phallic phase) on to the earlier sadistic-anal level. This phenomenon of regression is decisive for all that follows.

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too weak, but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express an absolute opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It rather tends to show that by the time an obsessional neurosis begins to show itself the phallic stage has already been attained. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria. It sets in in the second period of childhood, with the latency period. In a patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of his regression and of the emergence of his obsessional neurosis was a real occurrence that impaired a genital life which had up till then been intact.

As regards a metapsychological explanation of regression I am inclined to find it in a *defusion of instinct*, in a detachment of the erotic components which, at the beginning of the genital stage, had become joined to the destructive cathexes belonging to the sadistic phase.

In bringing regression about, the ego scores the first point in its defensive struggle against the demands of the libido. In this connection we shall find it advantageous to distinguish the more general notion of *defence* from *repression*. Repression is only one of the mechanisms which defence makes use of. It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being warded off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the passing away of the Oedipus complex, the

creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses, these processes are carried further than is normal. In order to effect the destruction of the Oedipus complex, a regressive degradation of the libido takes place as well, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity, and cleanliness. Implacable, though not therefore always successful, severity is shown in putting down the temptation to continue early infantile masturbation which is now attached to regressive (sadistic-anal) ideational images but which still represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (castration anxiety), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of abolishing the Oedipus complex. We once more find an illustration of the truth that every exaggeration contains the seed of its own destruction. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to gratification.

The reaction-formations in the ego of the obsessional neurotic, which we have recognized as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed on the same level as regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse and leaves it to pursue its course in the unconscious, taking no further part in its lot. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.

We can either simply accept it as a fact that in obsessional neurosis a super-ego of this severe kind emerges, or we can take the regression of the libido as the fundamental characteristic of the affection and attempt to relate the severity of the super-ego to it. And indeed, the super-ego, originating as it does in the id, cannot dis-

sociate itself from the regression and defusion of instinct which have taken place there. We cannot be surprised if it becomes harsher, unkind, and more tormenting than where development has been normal.

The chief task during the latency period seems to be the warding off of the temptation to masturbate. This struggle produces a series of symptoms which appear in a typical fashion in the most different individuals and which bear the general character of ceremonial. It is a great pity that no one has as yet collected them and systematically analysed them. Being the earliest products of the neurosis, they should best be able to shed light on the mechanisms employed in its symptom-formation. They already exhibit those features which are destined to come to the fore so fatefully in the serious illness that lies ahead—the manner in which the symptoms are introduced into certain procedures (which later on become almost automatic) in connection with going to sleep, washing, dressing, and walking about, as well as the tendency to repetition and delay. Why this should be so is at present not at all clear; but the sublimation of anal-erotic components plays an unmistakable part.

The advent of puberty opens a new chapter in the history of an obsessional neurosis. The organization at the genital level which has been stopped in childhood starts again with great vigour. But, as we know, the sexual development of the child determines what direction this new start will take. Not only will the early aggressive impulses be reawakened; but a greater or lesser proportion of the new libidinal impulses—in bad cases the whole of them—will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including many which it would otherwise not have taken exception to. The super-ego, overstrict as it is, insists all the more strongly on the suppression of sexuality, seeing that the latter has assumed such repulsive forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and

the forces that are to be kept off more intolerable. Both effects are due to one factor, namely, regression of the libido.

Much of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves conscious. But there is no doubt that before becoming conscious they have been through a process of repression. In most of them the actual text of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like, and confused nature, or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse, it has certainly abolished its accompanying affective quality, with the result that the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely an *idea* which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect which has been left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real formulation and full affective quality of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent must, on the other, accept a sense of guilt and carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego.<sup>1</sup> If it is asked why the ego does not also attempt to withdraw itself from the painful criticism of the super-ego, the simple answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a new set of symptoms, penances, or restrictions of a self-punishing kind. These symptoms represent at the same time a gratification of masochistic impulses which, in their turn, have been reinforced by regression.

Obsessional neurosis presents such a vast

multiplicity of phenomena that we have never yet succeeded in making a coherent synthesis of all its variations. All we can do is to pick out certain typical correlations; but there is always the risk that we may have overlooked other uniformities of a no less important kind.

I have already described the general tendency of symptom-formation in obsessional neurosis. It is to give ever greater room to substitutive gratification at the expense of frustration. Symptoms which once stood for a restriction of the ego come later on to represent gratifications as well, thanks to the ego's inclination to synthesize, and it is quite clear that this second meaning gradually becomes the more important of the two. The result of this process, which approximates more and more to a complete failure of the original purpose of defence, is an extremely restricted ego which is reduced to seeking gratification in the symptoms. The displacement of the distribution of forces in favour of gratification may have the alarming outcome of paralysing the will of the ego, so that in every decision that it has to make it is almost as strongly impelled from the one side as from the other. The acute conflict between id and super-ego which has dominated the illness from the very beginning may assume such extensive proportions that the ego, unable to carry out its office of mediator, can undertake nothing which is not drawn into the sphere of that conflict.

## CHAPTER VI

In the course of these struggles, two activities of the ego of a symptom-forming kind are observable, which deserve special attention because they are obviously surrogates of repression and therefore well suited to illustrate its purpose and technique. The fact that such auxiliary and substitutive techniques emerge may argue that true repression has met with difficulties in its functioning. If one considers how much more the ego is the scene of action of symptom-formation in obsessional neurosis than it is in hysteria and with what tenacity it clings to its relations to reality, employing all its intellectual faculties to that end—so much so that the very process of thinking becomes hyper-cathected and eroticized—then one may perhaps get a closer idea of the importance of these variations of repression.

The two techniques I refer to are *undoing what has been done* and *isolating*. The first of these has a wide range of application and goes back very far. It is, as it were, a negative magic,

<sup>1</sup> Cf. Theodor Reik, *Geständniszwang und Strafbedürfnis*, 1925, p. 51.

and endeavours, by means of motor symbolism, to "blow away" not merely the consequence of some occurrence, experience, or impression, but those very events themselves. I choose the term "blow away" advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs, and religious ceremonies as well. In obsessional neurosis we first come across the technique of undoing what has been done in symptoms which occur in two phases—*dichronous* symptoms—in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonies, the first being to take precautions in order to prevent the occurrence or recurrence of some given event. The difference between the two is easily seen: the precautionary measures are rational, whilst the measures taken to abolish something by undoing it are irrational and magical. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from an animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply look away from it and its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same aim may perhaps be present in and account for the compulsion to repeat actions which is so frequently met with in obsessional neuroses and which serves a number of contradictory purposes at once. When anything has not happened in the desired way, it can be undone by being repeated in a different way; and now all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that one symptom-forming motive of first-rate importance is the endeavour to undo a traumatic experience. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

The second of these techniques that we are setting out to describe for the first time, that of isolation, is characteristic for obsessional neurosis. It, too, takes place in the motor sphere. When the subject has done something which has a significance for his neurosis, or after something unpleasant has happened, he

will interpolate an interval during which nothing further may happen—during which he may perceive nothing and do nothing. This behaviour, which seems so strange at first sight, is soon seen to have a relation to repression. We know that in hysteria a traumatic experience is able to be overtaken by amnesia. In obsessional neurosis this can often not be achieved. But, instead of being forgotten, the experience is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of isolation is thus the same as the effect of repression with amnesia. This technique is, then, carried out in the isolations of obsessional neurosis. It is at the same time reinforced in a magical sense from the motor sphere. The elements that are held apart in this way are precisely those which belong together associatively. Motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure. The normal person concentrates on what seems to him important in the way of an impression or a piece of work in order that it shall not be interfered with by the intrusion of any other mental processes or activities. But even he uses concentration to keep away not only what is irrelevant or unimportant to the matter in hand, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged to it but which have been discarded in the course of his development—as, for instance, by any manifestation of the ambivalence belonging to his father complex in his relation to God, or by any impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, in carrying out our analytic technique we have to train it to relinquish that function, eminently justified as it is in itself, for the time being.

All analysts have found that it is especially difficult for the obsessional neurotic to carry out the fundamental rule of psycho-analytic treatment. Probably his ego is more watchful and makes sharper isolations because of the high degree of tension due to conflict that exists between his super-ego and his id. While his thoughts are working, his ego has to keep off too much in the way of an intrusion of uncon-

scious phantasies or a manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies its compulsion to concentrate and to isolate by the help of those magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are actually, of course, useless and in the nature of ceremonials.

But in thus endeavouring to prevent associations and connections of thought, the ego is obeying one of the oldest and most fundamental commands of obsessional neurosis, the taboo of touching. If one asks oneself why the avoidance of touching, contact, or contamination should play such a large part in this neurosis and should become the subject-matter of complicated systems, the answer is that touching and physical contact are the immediate aim of the aggressive as well as the loving object-cathexes. Eros desires contact because it strives to make the ego and the loved object one, to abolish all barriers of distance between them. But the first requisite of destructiveness, too, which (before the invention of long-range weapons) can only take effect at close quarters, is physical contact, a coming to grips. To *touch* a woman has become a euphemism for using her as a sexual object. No to *touch* one's genitals is the phrase employed for forbidding auto-erotic gratification. Since obsessional neurosis begins by persecuting touching in its erotic sense and then, after regression has taken place, goes on to persecute it in its new sense of aggressiveness, nothing is so strongly proscribed in this illness as touching nor so well suited to become the central point of a system of prohibitions. Now, to isolate a thing is to banish the possibility of its being touched, to withdraw it from any sort of contact. When a neurotic isolates an impression or an activity by interpolating an interval, he lets it be understood symbolically that he will not allow his thoughts about that impression or activity to come into associative contact with his other thoughts.

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion-hysteria, and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a

very serious problem the consideration of which can no longer be put off. All three have as their starting-point the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged as such. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recollect the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, as it were, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression or defence? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration *complex*, we can hardly speak with propriety of castration *anxiety* where castration has already taken place.

## CHAPTER VII

LET us go back again to infantile phobias of animals; for we still know more about them than any others. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id—a cathexis that belongs either to the positive or the negative Oedipus complex—because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In Little Hans's case—that is, in the case of a positive Oedipus complex—was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence of the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the instinct of destruction; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that, after Hans's phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the symptom-formation (substitutive formation) took place in relation to his aggressive impulses. In the Wolf Man the situation was simpler. The impulse that was

repressed was his feminine attitude towards his father, and that attitude was a genuinely erotic one. And it was in relation to that impulse, too, that the formation of his symptoms took place.

It is almost humiliating that, after working so long, we should still be having difficulty in understanding the most fundamental facts. But we are determined to simplify nothing and to hide nothing. If we cannot see things clearly, we will at least see clearly what the obscurities are. What is hampering us here is evidently some hitch in the development of our theory of the instincts. We began by tracing the organization of the libido through its successive stages—from the oral through the sadistic-anal to the genital—and in doing so placed all the components of the sexual instinct on the same footing. Later it appeared that sadism was the representative of another instinct which was opposed to Eros. This new view, that the instincts fell into two groups, seems to explode the earlier view of the successive stages of libidinal organization. But we do not have to break fresh ground in order to find a way out of the difficulty. The solution has been at hand for a long time and consists in the fact that what we are concerned with are scarcely ever pure instinctual impulses but mixtures in various proportions of the two groups of instincts. If this is so, there is no need to revise our view of the organizations of the libido. A sadistic cathexis of an object may legitimately claim to be treated as a libidinal one; and an aggressive impulse against the father can just as well be subjected to repression as a loving impulse towards the mother. Nevertheless we shall bear in mind for future consideration the possibility that repression is a process which has a special relation to the genital organization of the libido and that the ego resorts to other methods of defence when it has to secure itself against the libido on other levels of organization. A case like Little Hans's does not enable us to come to any clear conclusion. It is true that in him an aggressive impulse had been disposed of by repression, but this happened after the genital organization had been attained.

This time we will keep our attention on the question of anxiety. We have said that as soon as the ego recognized the danger of castration it gave the signal of anxiety and inhibited through the pleasure-unpleasure system (in a way which we cannot as yet understand more fully) the impending cathetic process in the id. At the same time the phobia became formed;

and now the castration anxiety was directed to a different object and expressed in a distorted form, so that the patient was afraid, not of being castrated by his father, but of being bitten by a horse or eaten by a wolf. This substitutive formation had two obvious advantages. In the first place it avoided a conflict due to ambivalence (for the father had been a loved object, too), and in the second place it enabled the ego to cease producing anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived, and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand, one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it—that is, its presence—in order to be free from danger and anxiety. Little Hans, therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not always been showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fears.

On a previous occasion I have stated that phobias have the character of a projection, in that they replace an internal, instinctual danger by an external, perceptual one. The advantage of doing this comes from the fact that the individual can protect himself against external dangers by fleeing from them and avoiding the perception of them, whereas it is useless to try to flee from dangers that arise from within. This statement of mine was not incorrect, but it did not go below the surface of things. For an instinctual demand is, after all, not dangerous in itself; it only becomes so inasmuch as it entails a real external danger, the danger of castration. Thus what happens in a phobia in the last resort is merely that one external danger is replaced by another. The view that in a phobia the ego is able to escape anxiety by means of avoidance or inhibitory symptoms fits in with the theory that that anxiety is only an affective signal and that no alteration has taken place in the economic situation.

The anxiety felt in animal phobias is, therefore, an affective reaction on the part of the ego to danger; and the danger which is being

signalled in this way is the danger of castration. This anxiety differs in no respect from the anxiety which the ego normally feels in situations of danger except that its content remains unconscious and only becomes conscious in the form of a distortion.

The same is true, I think, of the phobias of grown-up persons, although the material that undergoes modification in their neuroses is much more abundant, and there are some additional factors in the formation of the symptoms. Fundamentally the position is identical. The agoraphobic patient imposes a restriction upon his ego so as to escape a certain instinctual danger, namely, the danger of giving way to his erotic desires. For, if he did so, the danger of being castrated, or some similar danger, would once more be conjured up as it was in his childhood. I may cite as an instance the case of a young man who became agoraphobic because he was afraid of yielding to the solicitations of prostitutes and of contracting a syphilitic infection from them as a punishment.

I am well aware that a great number of cases exhibit a much more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia, for example, is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy, or, in extreme cases, to pre-natal days, that is, to a time when the individual was in his mother's womb and protected against the dangers which beset him in the present. A regression of this kind now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone, provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations will depend in each case upon the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Naturally, infantile

regression can only take place when the individual is no longer a child.

A phobia generally sets in only after a first anxiety attack has been experienced in specific circumstances, such as in the street or in a train or in solitude. Thereafter the anxiety is held in ban by the phobia, but it re-emerges whenever the protective stipulation cannot be fulfilled. The mechanism of phobia does good service as a means of defence and tends to be very stable. A continuation of the defensive struggle, in the shape of a struggle against the symptom, occurs frequently but not invariably.

What has been said about anxiety in phobias is true of obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on a level with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of the super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the behests, precautions, and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an acute feeling of discomfort which may, I think, be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

The conclusion we have come to, then, is this. Anxiety is a reaction to a situation of danger. It is obviated by the ego's doing something to avoid that situation or to withdraw from it. It might be said that symptoms are created so as to prevent anxiety from emerging. But this does not go deep enough. It would be truer to say that symptoms are created so as to avoid a danger-situation whose approach has been signalled by the emergence of anxiety. In the cases that we have discussed, the danger concerned was the danger of castration or some off-shoot of castration.

If anxiety is a reaction of the ego to danger, we shall be tempted to regard the traumatic neuroses, which so often follow upon a narrow escape from death, as a direct result of a fear of

death (or fear *for* life) and to dismiss from our minds the question of castration and the subordinate relations of the ego. Most physicians who observed the traumatic neuroses that occurred during the great war took this line and triumphantly announced that proof was now forthcoming that a threat to the instinct of self-preservation could by itself produce a neurosis without any admixture of sexual factors and without requiring any of the complicated hypotheses of psycho-analysis. It is in fact greatly to be regretted that not a single analysis of a traumatic neurosis of any value is extant. And it is to be regretted, not because such an analysis would contradict the aetiological importance of sexuality—for any such contradiction has long since been disposed of by the introduction of the concept of narcissism, which brings the libidinal cathexis of the ego into line with the cathexes of objects and emphasizes the libidinal character of the instinct of self-preservation—but because, in the absence of any analyses of this kind we have lost a precious opportunity of making decisive discoveries about the relations between anxiety and the formation of symptoms. In view of all that we know about the structure of the comparatively simple neuroses of everyday life, it would seem highly improbable that a neurosis could come into being merely because of the objective presence of danger without any participation of the deeper levels of the mental apparatus. But the unconscious seems to contain nothing that would lend substance to the concept of the annihilation of life. Castration can be pictured on the basis of the daily experience of the faeces being separated from the body or on the basis of losing the mother's breast at weaning. But nothing resembling death can ever have been experienced; or if it has, as in fainting, it has left no observable traces behind. I am therefore inclined to adhere to the view that the fear of death should be regarded as analogous to the fear of castration and that the situation to which the ego is reacting is one of being abandoned by the protecting super-ego—the powers of destiny—so that it has no longer any safeguard against all the dangers that surround it. In addition, it must be remembered that in those experiences which lead to a traumatic neurosis the protective barrier against external stimuli has been broken through and over-great quantities of excitation impinge upon the mental apparatus; so that we have here the second possibility, that anxiety is not only being signalled as an

affect but is also being created anew out of the economic conditions of the situation.

The statement I have just made, to the effect that the ego has been prepared to expect castration by having undergone constantly repeated object-losses, places the question of anxiety in a new light. We have hitherto regarded it as an affective signal of danger. But now, since the danger is so often one of castration it appears to us as a reaction to a loss, a separation. Even though many considerations immediately arise which make against this view, we cannot but be struck by one very remarkable correlation. The first experience of anxiety through which the individual goes is (in the case of human beings, at all events) birth, and, objectively speaking, birth is a separation from the mother. It can be compared to a castration of the mother (by equating the child with a penis). Now it would be very satisfactory if anxiety, as a symbol of separation, were to be repeated on every subsequent occasion on which a separation took place. But unfortunately we are prevented from making use of this correlation by the fact that birth is not experienced subjectively as a separation from the mother, since the foetus, being a completely narcissistic creature, is totally unaware of her existence as an object. Another adverse argument is that we know what the affective reactions to separation are: they are pain and mourning, not anxiety. Incidentally, it may be remembered that in discussing the question of mourning<sup>1</sup> we also failed to discover why it should be such a painful thing.

## CHAPTER VIII

THE time has come to pause and reflect. What we clearly want is some idea of what anxiety really is, some criterion that will enable us to distinguish true statements about it from false ones. But this is not easy to get. Anxiety is not so simple as all that. Up till now we have arrived at nothing but contradictory views about it, none of which can, to the unprejudiced eye, be given preference over the other. I therefore propose to adopt a different procedure. I propose to assemble, quite impartially, all the facts that we do know about anxiety and to give up the idea of making any immediate synthesis of them.

Anxiety, then, is in the first place something that is felt. We call it an affective state, although we are also ignorant of what an affect

<sup>1</sup> "Mourning and Melancholia" (1917), *Collected Papers*, IV.

is. As a feeling, anxiety has a very marked quality of unpleasure. But that is not the whole of its quality. Not every unpleasure is anxiety, for there are other sensations, such as tension, pain, or mourning, which have the quality of unpleasure. Thus anxiety must have other distinctive features besides this quality. Can we succeed in finding out what the differences are between these various unpleasurable affects?

We can at any rate note one or two things about the feeling of anxiety. Its unpleasurable quality seems to have a character of its own—something not very obvious, whose presence is difficult to prove yet which is in all likelihood there. But besides having this special character which is difficult to isolate, we notice that anxiety is accompanied by fairly definite physical sensations which can be referred to particular organs of the body. As we are not concerned here with the physiology of anxiety, we shall content ourselves with mentioning a few examples of these sensations. The clearest and most frequent ones are those connected with the respiratory organs and with the heart. They provide evidence that motor innervations, i.e., processes of discharge, play a part in the general phenomenon of anxiety.

Analysis of anxiety states therefore reveals the existence of (1) a specific quality of unpleasure, (2) acts of discharge, and (3) perceptions of those acts. The two last points indicate at once a difference between states of anxiety and other similar states, like those of mourning and pain. The latter do not have any motor manifestation; or if they have, the manifestation is not an integral part of the whole state but is distinct from it as being a result of it or a reaction to it. Anxiety, then, is a special state of unpleasure, with acts of discharge along particular channels. In accordance with our general views we should be inclined to think that anxiety is based upon an increase of excitation which, on the one hand, produces the quality of unpleasure and, on the other, finds relief through the channels of discharge mentioned above. But a purely physiological account of this sort is scarcely sufficient. We are tempted to assume the presence of a historical factor which binds the sensations of anxiety and its innervations firmly together; in other words, that an anxiety state is the reproduction of some experience which contains the necessary conditions for such an increase of excitation and a discharge along particular channels, and that from this circumstance the unpleasure of anxiety receives its specific

character. In man, birth is a prototypic experience of this kind, and one is therefore inclined to regard anxiety states as a reproduction of the trauma of birth.

This does not imply that anxiety occupies a different position from all the other affective states. In my opinion, the other affects are also reproductions of very early, perhaps even pre-individual, experiences of vital importance; and I should be inclined to regard them as universal, typical, and innate hysterical attacks, comparable with the recently and individually acquired attacks which occur in hysterical neuroses and whose origin and significance as memory symbols have been revealed by analysis. Of course it would be very desirable to be able to demonstrate the truth of this view in a number of such affects—a thing which is still very far from being the case.

Certain immediate objections to this view that anxiety goes back to the event of birth have to be met. It may be argued that anxiety is a reaction which, in all probability, is common to every organism, certainly every organism of a higher order, whereas birth is only experienced by the mammals; and it is doubtful whether in all of them, even, birth amounts to a trauma. Therefore, there can be anxiety without the prototype of birth. But this objection takes us beyond the barrier that divides psychology from biology. It may be precisely because anxiety has an indispensable biological function to fulfil as a reaction to a state of danger that it is differently fashioned in different living beings. We do not know, besides, whether anxiety involves the same sensations and innervations in creatures far removed from man as it does in man himself. Thus there is no good argument here against the view that, in man, anxiety is modelled upon the process of birth.

If the structure and origin of anxiety are as described, the next question is: what is the function of anxiety and on what occasions is it reproduced? The answer seems to be obvious and convincing: anxiety arose originally as a reaction to a state of danger, and it is reproduced whenever a state of that kind recurs.

This answer, however, raises further considerations. The innervations involved in the original state of anxiety probably had a meaning and purpose, just as have the muscular movements which accompany a first hysterical attack. In order to understand an hysterical attack, all one has to do is to look for a situation in which the movements in question would form

part of an appropriate and expedient action. Thus in birth it is probable that the innervations, in being directed to the respiratory organs, are preparing the way for the activity of the lungs, and that in accelerating the heart-beat they are helping to keep the blood free from toxic substances. Naturally, when the anxiety state is reproduced later on as an affect, it will be lacking in any such expediency, just as the repetitions of a hysterical attack are. When the individual is placed in a new situation of danger, it may well be quite inexpedient for him to respond with an anxiety state (which is a reaction to an earlier danger) instead of initiating a reaction which is appropriate to the present danger. But his behaviour may become expedient once more if he recognizes the danger-situation before it has actually overtaken him and signals its approach by an outbreak of anxiety. In that case, he can at once get rid of his anxiety by having recourse to more suitable measures. Thus we see that there are two ways in which anxiety can emerge: in an expedient way, when a new situation of danger has occurred, or in an inexpedient way, in order to give a signal and prevent such a situation from occurring.

But what is a *danger*? In the act of birth there is a real danger to life. We know what this means objectively; but what it means in a psychological sense we have no idea. The danger of birth has as yet no mental content for the subject. One cannot possibly suppose that the foetus has any sort of knowledge that its life is in danger of being destroyed. It can only be aware of some vast upheaval in the economy of its narcissistic libido. Very large quantities of excitation crowd in upon it, giving rise to new sensations of unpleasure, and many organs acquire an increased cathexis, thus foreshadowing the object-cathexis which will soon set in. What elements in all this can be considered to be distinctive of a *danger-situation*?

Unfortunately, far too little is known about the mental constitution of the new-born child to make a direct answer possible. I cannot even vouch for the validity of the description I have just given. It is easy to say that the baby will repeat its affect of anxiety in every situation which recalls the event of birth. The important thing to know is what it is that recalls that event and what it is in that event that is recalled.

All we can do is to examine the occasions on which infants or rather older children show

readiness to produce anxiety. In his book on the trauma of birth,<sup>1</sup> Rank has made a determined attempt to establish a relationship between the earliest phobias of children and the impressions made on them by the event of birth. But I do not think he has been successful. His theory is open to two objections. In the first place, he assumes that the infant has received certain sensory impressions, in particular of a visual kind, at the time of birth, the renewal of which can recall to its memory the trauma of birth and thus evoke a reaction of anxiety. This assumption is quite unfounded and extremely improbable. It is not credible that a child should retain any but tactile and general sensations relating to the process of birth. If, later on, children show fear of small animals that disappear into holes or emerge from them, this reaction, according to Rank, is due to their perceiving an analogy. But it is an analogy of which they cannot be aware. In the second place, in considering these later anxiety-situations Rank dwells, according as it suits him best, now on the child's recollection of its happy intra-uterine existence, now on its recollection of the traumatic disturbance which interrupted that existence; so that he is able to make almost any interpretation he pleases. There are, moreover, certain examples of childhood anxiety which directly traverse his theory. When, for instance, a child is left alone in the dark, one would expect it, according to his view, to welcome the re-establishment of the intra-uterine situation; yet it is precisely on such occasions that the child reacts with anxiety. And if this is explained by saying that the child is being reminded of the interruption which the event of birth made in its intra-uterine happiness, then one can no longer shut one's eyes to the far-fetched character of such explanations.

I am driven to the conclusion that the earliest phobias of infancy cannot be directly traced back to impressions of birth and that so far they have not been explained. A certain preparedness for anxiety is undoubtedly present in the infant. But this preparedness for anxiety, instead of being at its maximum immediately after birth and then slowly decreasing, does not emerge till later on, as the mental development of the infant proceeds. It lasts over a certain period of childhood. If the early phobias persist beyond that period, one is inclined to suspect the presence of a neurotic disturbance,

<sup>1</sup> Rank, *The Trauma of Birth and its Importance for Psycho-Analytic Therapy* (1924).

although here again it is not at all clear what their relation is to the undoubted neuroses that appear later on in childhood.

Only a few of the manifestations of anxiety in children are comprehensible to us, and we must confine our attention to them. They occur, for instance, when a child is alone or in the dark, or when it finds itself with an unknown person instead of one to whom it is used—such as its mother. These three instances can be reduced to a single condition, namely, that of missing someone who is loved and longed-for.

Here is the key, I think, to an understanding of anxiety and to a reconciliation of the contradictions that seem to beset it. The child's memory picture of the person longed-for is no doubt intensively cathected, probably in a hallucinatory way at first. But this has no effect; and now it seems as though the longing turns into anxiety. This anxiety has all the appearance of being an expression of the child's feeling of not knowing what to do, as though in its still undeveloped state it did not know how to cope with its cathexis of longing. Here anxiety seems to be a reaction to the felt loss of the object; and one is at once reminded of the fact that castration anxiety, too, is a fear of being separated from a highly valued object, and that the earliest anxiety of all—the primal anxiety of birth—is brought about on the occasion of a separation from the mother.

But our next reflection takes us a step beyond this question of loss of object. The reason why the infant in arms wants to perceive the presence of its mother is only because it already knows by experience that she gratifies all its needs without delay. The situation, then, that it regards as a *danger* and against which it wants to be safe-guarded is one of non-gratification, of a growing tension due to need, against which it is helpless. I think that if we adopt this view all the facts fall into place. The situation of non-gratification in which the amounts of stimulation rise to an unpleasant height without the infant being able to master them by utilizing and discharging them psychologically must be analogous for it to the experience of being born—must be a repetition of that situation of danger. What both situations have in common is an economic disturbance caused by an accumulation of amounts of stimulation which require to be disposed of. It is this element which is the real essence of the danger. In both cases the same reaction of anxiety sets in.

(This anxiety reaction is still an expedient one in the child at the sucking stage, for, just as it activated the lungs of the new-born baby to get rid of the internal stimuli, so now, in being discharged into the respiratory and vocal muscular apparatus, it calls the mother to the child's side.) It is unnecessary to suppose that the child carries with it from the time of its birth anything more than this way of indicating the presence of danger.

When the child has found out by experience that an external, perceptible object can put an end to the dangerous situation which is reminiscent of birth, the nature of the danger it fears is displaced from the economic situation on to the condition which determined that situation, viz., the loss of object. It is the absence of the mother that is now the danger; and as soon as that danger arises the small child gives the signal of anxiety, before the dreaded economic situation has set in. This change constitutes a first important step forward in the provision made by the child for its self-preservation, and at the same time represents a transition from the automatic and involuntary new-creation of anxiety to the intentional reproduction of anxiety as a signal of danger.

In these two aspects, as an automatic phenomenon and as a rescue-signal, anxiety is seen to be a product of the infant's mental helplessness which is a natural counterpart of its biological helplessness. The striking coincidence by which the anxiety of the new-born baby and the anxiety of the infant in arms both depend upon a separation from the mother does not need to be explained on psychological lines. It can be accounted for simply enough from a biological point of view; for, just as the mother originally satisfied all the needs of the foetus through her own body, so now, after its birth, she continues to do so, though partly through other means. There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of the act of birth allows us to believe. What happens is that the child's biological situation as a foetus is replaced for it by a psychological object-relation to its mother. But we must not forget that during its intra-uterine life the mother was not an object for the foetus, and that at that time there were no objects at all as far as it was concerned. It is obvious that in this scheme of things there is no room for the abreaction of the birth-trauma. We cannot find that anxiety has any other function except that

of being a signal for the avoidance of a danger-situation.

The importance of the loss of object as a determinant of anxiety extends considerably further. For the next transformation of anxiety, viz., the castration anxiety belonging to the phallic phase, is also a fear of separation and is thus attached to the same determinant. In this case the danger is of being separated from one's genitals. Ferenczi has traced, quite correctly, I think, a clear line of connection between this fear and the fears contained in the earlier situations of danger. According to him, the high degree of narcissistic value which the penis possesses is due to the fact that this organ is a guarantee to its owner that he can be once more united to his mother—i.e., to a substitute for her—in the act of copulation. Being deprived of it amounts to a renewed separation from her and this in its turn means being helplessly exposed to an unpleasurable tension due to instinctual need, as was the case in birth. But this need whose increase is feared is now a specific one belonging to the genital libido and is no longer an indeterminate one, as in the period of infancy. It may be added that for a man who is impotent (that is, who is inhibited by the threat of castration) the substitute for copulation is a phantasy of returning into his mother's womb. Following out Ferenczi's line of thought, one might say that such a man, while endeavouring to return to his mother's womb vicariously—by means of his genital organ, proceeds to replace that organ regressively by his body as a whole.

The progress which the child makes in its development—its growing independence, the sharper division of its mental apparatus into several institutions, the advent of new needs—cannot fail to exert an influence upon the content of the danger-situation. We have already traced the change of that content from loss of the mother as an object to castration. The next change is enforced by the power of the super-ego. With the depersonalization of the parental institution from which castration was feared, the danger becomes less defined. Castration anxiety develops into moral anxiety—social anxiety—and it is not so easy now to know what the anxiety is about. The formula, *separation and expulsion from the horde*, only applies to that later portion of the super-ego which has been formed on the strength of social prototypes, not to the nucleus of the super-ego which corresponds to the introjected parental institution. Putting it more generally.

what the ego regards as the danger and responds to with an anxiety-signal is that the super-ego should be angry with it or punish it or cease to love it. The final transformation which the fear of the super-ego undergoes is, it seems to me, the fear of death (or fear for life) which is a fear of the super-ego projected on to the powers of destiny.

At one time I attached some importance to the view that what found discharge in anxiety was the cathexis which had been withdrawn in the process of repression. This view seems to me no longer of any interest. The reason for this is that whereas I formerly believed that anxiety invariably arose automatically through an economic process, my present conception of anxiety as a signal given by the ego in order to affect the pleasure-unpleasure institution does away with the necessity of considering the economic factor. Of course there is nothing to be said against the idea that it is precisely the energy that has been liberated by being withdrawn through repression which is used by the ego to arouse affect; but it is no longer of any importance which portion of the general energy is employed for this purpose.

This new view of things calls for an examination of another proposition of mine, namely, that the ego is the actual seat of anxiety. I think this proposition still holds good. There is, as far as can be seen, no reason to assign any manifestation of anxiety to the super-ego; while the expression *anxiety of the id* stands in need of correction, though rather as to its form than its substance. Anxiety is an affective state and as such can, of course, only be felt by the ego. The id cannot have anxiety as the ego can; for it is not an organization and cannot make a judgment about a situation of danger. On the other hand it very often happens that processes take place or begin to take place in the id which cause the ego to produce anxiety. Indeed, it is probable that the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to processes in the id. Here again one may rightly distinguish between the case in which something occurs in the id which activates a danger-situation for the ego and induces the latter to give the anxiety signal for inhibition to take place, and the case in which a situation analogous to the trauma of birth is established in the id and an automatic reaction of anxiety ensues. The two cases may be brought closer together if it is pointed out that the second case applies to the earliest and original danger-situation, while the first case

applies to any one of the later determinants of anxiety that have been derived from it; or, with regard to psychological disorders, that the second case is operative in the aetiology of the actual neuroses, while the first remains typical for that of the psychoneuroses.

We see, then, that it is not so much a question of taking back our earlier findings as of bringing them into line with more recent discoveries. It is still an undeniable fact that, in sexual abstinence, improper interference with the processes of sexual excitation, or deflection of the latter from its psychological modification, anxiety arises directly out of libido; in other words, that the ego is reduced to a state of helplessness in the face of an excessive tension due to need, as it was in the situation of birth, and that anxiety is then produced. Here once more, though the matter is of little importance, it is very possible that what finds discharge in anxiety is precisely the surplus of unutilized libido. As we know, a psychoneurosis is especially liable to develop on the basis of an actual neurosis. This looks as though the ego were attempting to save itself from anxiety, which it has learned to keep in suspension for a while, and to bind it by the formation of symptoms. Analysis of the traumatic war-neuroses—a term which, by the way, covers a great variety of disorders—would probably have shown that a number of them possess the characteristics of actual neuroses.

In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that as the development of the ego goes on the earlier danger-situations tend to lose their force and to be set aside, so that one might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychological helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a later period than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a close relationship between the danger-situation that is operative at a given

moment and the form taken by the ensuing neurosis.<sup>1</sup>

When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic affection, we put ourselves on guard against over-estimating that factor, since it could not be a decisive one for the female sex, and since women are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how the little girl, in the course of her development, is led to make a loving object-cathexis through her castration complex. It is precisely in women that the danger-situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing, the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with the nature of women, just as obsessional neurosis has with that of men, it appears probable that, as a determinant of anxiety, loss of love plays much

<sup>1</sup> Since the differentiation of the ego and the id, our interest in the problems of repression cannot fail to have received a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego—the keeping away from consciousness and from motility, and the formation of substitutes (symptoms). With regard to the instinctual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed, and we begin to suspect that it is not self-evident, perhaps not even the usual thing, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the unconscious portion of them maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, are the old desires, about whose former existence analysis tells us, still there? The answer seems ready to hand and certain. It is that the old, repressed desires must still be present in the unconscious, since we still find their derivatives, the symptoms, at work. But this answer is not sufficient. It does not enable us to decide between two possibilities, either that the old desire is now operating only through its derivatives, having transferred the whole of its cathectic energy to them, or that it is itself still alive too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become reanimated by regression, anachronistic though it be. These are no idle speculations. There are many things about mental life, both normal and pathological, which seem to call for questions of this kind. In my paper, "The Passing of the Oedipus-Complex" (*Collected Papers*, II [1924]). I had occasion to notice the difference between mere repression and the real removal of an old conative impulse.

the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

## CHAPTER IX

WHAT we have now to do is to consider the relationship between the formation of symptoms and the production of anxiety.

There seem to be two very widely held opinions on this subject. One is that anxiety is itself a neurotic symptom. The other is that there is a much more intimate relation between the two: According to the second opinion, symptoms are only formed in order to avoid anxiety: they bind the mental energy which would otherwise be discharged as anxiety. Thus anxiety would be the fundamental phenomenon and main problem of neurosis.

That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will have an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of having a companion in the street or of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense, every inhibition which the ego imposes upon itself can be called a *symptom*.

Since we have traced back the production of anxiety to a situation of danger we should prefer to say that symptoms are created in order to remove the ego from a situation of danger. If the symptoms are prevented from being formed, the danger does in fact materialize; that is, a situation analogous to birth is established in which the ego is helpless in the face of a constantly increasing instinctual demand—the earliest and original determinant of anxiety. Thus in our view the relation between anxiety and symptom is less close than was supposed, for we have inserted the factor of the danger-situation between them. We can also add that the production of anxiety sets symptom-formation going and is, indeed, a necessary pre-requisite of it. For if the ego did not arouse the pleasure-unpleasure institution by developing anxiety, it would not have the power to arrest the process which is preparing in the id and which threatens danger. There is in all this an evident inclination to limit to a minimum the amount of anxiety developed and to employ it only as a signal; for to do more

would only be to feel in another place the unpleasure which the instinctual process was threatening to produce, and that would not be a good result from the standpoint of the pleasure-principle, although it is one that occurs often enough in the neuroses.

The formation of symptoms, then, does in effect put an end to the danger-situation. It has two aspects: one, hidden from view, brings about those alterations in the id in virtue of which the ego is removed from danger; the other presents to the world what the symptom-formation has created in place of the instinctual process which has been affected—namely, the substitutive formation.

It would, however, be more correct to ascribe to the defensive process what we have just said about symptom-formation and to use the latter term as synonymous with substitute-formation. It will then be clear that the defensive process is analogous to the method adopted by the ego for removing itself from a danger that threatens it from outside, that is, to flight. The defensive process is an attempt at flight from an instinctual danger. An examination of the weak points in this comparison should prove informative. One thing that can be said against it is that the loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from without as, say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack a man irrespective of his behaviour towards it; but the loved person would not cease to love him, nor would he be threatened with castration if he did not entertain certain feelings and intentions in his mind. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and the individual can proceed against the external dangers by taking measures against the internal ones. In phobias of animals, the danger seems to be still entirely felt as an external one, just as it has undergone an external displacement in the symptoms. In obsessional neuroses, the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety represents an internal substitute for an external danger, while the other portion—moral anxiety—is already completely endo-psychic.

Another objection is that in taking flight from an impending external danger all that the subject does is to increase the distance between himself and what is threatening him. He does not

prepare to defend himself against it or attempt to alter anything about it, as would be the case if he attacked the wolf with a stick or shot at it with a gun. Now the defensive process seems to do something more than would correspond to an attempt at flight. It joins issue with the threatening instinctual process and somehow suppresses it or deflects it from its aims and thus renders it innocuous. This objection seems unimpeachable and must be given due weight. I think it is probable that there are some defensive processes which can truly be likened to an attempt at flight, while in others the ego takes a much more active line of self-protection and initiates vigorous counter-measures. But perhaps the whole analogy between defence and flight is invalidated by the fact that both the ego and the instinct in the id are parts of the same organization, not separate entities like the wolf and the child, so that any kind of behaviour on the part of the ego will result in an alteration in the instinctual process as well.

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego in a rational light. Each situation of danger corresponds to a particular period of life or developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not fitted to master psychologically the large quantities of excitation that impinge upon him, whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, his conscience; for the absence of that factor would give rise for him to severe conflicts, dangers, and so on.

But this last point raises a new problem. Instead of the affect of anxiety, let us take, for a moment, another affect, say that of pain. It seems quite normal that at four years of age a girl should weep painfully if her doll is broken; or at six, if her schoolmistress reproves her;

or at sixteen, if she is slighted by her young man; or at twenty-five, if a child of her own dies. Each of these determinants of pain has its own time and each passes away when that time is over. Only the final and definitive determinants remain throughout life. We should think it rather unusual if this same girl, after she had grown to be a wife and mother, were to cry over some worthless trinket that had been damaged. Yet that is how the neurotic behaves. Although all the institutions for mastering stimuli have long ago been developed within wide limits in his mental apparatus, and although he is sufficiently grown-up to gratify most of his needs for himself and has long ago learnt that castration is no longer practised as a punishment, he nevertheless behaves as though the old danger-situations still existed, and retains all the earlier determinants of anxiety.

Why this should be so requires a rather long answer. First of all, let us see what the facts are. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of infants, which consist in being afraid of being alone or in the dark or among strangers—phobias which can almost be called normal—usually pass off later on; the child "grows out of them," as we say about many other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate, and many conversion-hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period but only a very small proportion of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise

of a syphilidophobia, after he has got to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Furthermore, some determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany the individual throughout his life. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

These minor rectifications cannot in any way alter the main fact that a great many people remain infantile in their behaviour in regard to danger and do not overcome age-old determinants of anxiety. To deny this would be to deny the existence of neurosis, for it is precisely such people whom we call neurotics. But how is this possible? Why are not all neuroses episodes in the development of the individual which come to a close when the next phase is reached? Whence comes the element of persistence in these reactions to danger? Why does the affect of anxiety alone seem to enjoy the advantage over all other affects of evoking reactions which are distinguished from the rest in being abnormal and which, through their inexpediency, run counter to the movement of life? In other words, we have once more unexpectedly come upon the riddle which has so often confronted us: whence does neurosis come—what is its ultimate, its own peculiar meaning? After whole decades of psycho-analytic work, we are as much in the dark about this problem as ever.

## CHAPTER X

ANXIETY is the reaction to danger. One cannot help suspecting, however, that the reason why the affect of anxiety occupies a unique position in the economy of the mind has something to do with the essential nature of danger. Yet danger is a universal human experience; dangers are the same for everybody. What we need and cannot lay our finger on is some factor which will explain why some people are able to subject the affect of anxiety, in spite of its unique quality, to the ordinary workings of the mind, or why others are doomed to break down

over this task. Two attempts to find a factor of this kind have been made; and it is natural that such efforts should meet with a sympathetic reception, since they set out to fill a most urgent need. The two attempts in question are mutually complementary; they approach the problem at opposite ends. The first was made by Alfred Adler more than ten years ago.<sup>1</sup> He maintained in essence that it was those individuals who were too greatly impeded by some organic inferiority who failed to master the task set before them by danger. If it were true that *simplex sigillum veri*,<sup>2</sup> we should welcome this answer as a perfect solution of the problem. But on the contrary, our critical studies of the last ten years have effectively demonstrated the total inadequacy of such an explanation—an explanation, moreover, which sets aside the whole wealth of material that has been discovered by psycho-analysis.

The second attempt was made by Otto Rank in 1923 in his book, *The Trauma of Birth*. It would be unjust to put his attempt on the same level as Adler's except in this single point which concerns us here, for it remains upon psycho-analytic ground and pursues a psycho-analytic line of thought, so that it may be accepted as a legitimate endeavour to solve the problems of analysis. In this matter of the relation of the individual to danger, Rank moves away from the question of organic defect in the individual and concentrates on the variable degree of intensity of the danger.

The event of birth is the first situation of danger and the economic upheaval which it produces becomes the prototype of reaction to anxiety. We have already traced the line of development which connects this first danger-situation and determinant of anxiety with all the later ones, and we have seen that they all retain a common quality in so far as they signify in some way a separation from the mother—at first only in a biological sense, next as a direct loss of object and later as a loss of object indirectly incurred. The discovery of this extensive concatenation is an undoubted achievement of Rank's constructive work. Now the trauma of birth overtakes each individual with a different degree of intensity, and the violence of his anxiety-reaction varies with the strength of the trauma. According to Rank, whether the individual will ever learn to control his anxiety—whether he will become normal or neurotic—will depend upon the intensity

<sup>1</sup> Written in 1926.—TR.

<sup>2</sup> Simplicity is the seal of truth.—EP.

of the initial anxiety that is thus produced in him.

It is not our business to criticize Rank's hypothesis in detail here. All we need to do is to consider whether it helps to solve the particular problem before us. His proposition that those persons become neurotic in whom the trauma of birth was so strong that they have never been able completely to ab-react it is highly dubious from a theoretical point of view. We do not rightly know what is meant by ab-reacting a trauma. Taken literally, it implies that the more frequently and the more intensely a neurotic person reproduces affects of anxiety the more closely will he approach to mental health. This conclusion is not tenable. It was because it did not tally with the facts that I gave up the theory of ab-reaction which had played such a large part in the cathartic method. To lay so much stress on the variability in the strength of the birth trauma is to leave no room for the legitimate claims of hereditary constitution as an aetiological factor. For this variability is an organic factor which operates in an accidental fashion in relation to the constitution and is itself dependent on many influences which might be called accidental—as, for instance, upon timely assistance in child-birth. Rank's theory completely ignores constitutional factors as well as phylogenetic ones. If, however, we were to try to find a place for the constitutional factor by qualifying his statement with the proviso, let us say, that what is really important is the extent to which the individual reacts to the variable intensity of the trauma of birth, we should be depriving his theory of its significance and should be relegating the new factor introduced by him to a position of minor importance: the factor which decided whether a neurosis should supervene or not would lie in a different, and once more in an unknown, field.

Moreover, the fact that, while man has the process of birth in common with the other mammals, he alone is privileged to possess a special predisposition to neurosis is hardly favourable to Rank's theory. But the main objection to his theory is that it floats in the air instead of being based upon ascertained observations. No body of evidence has been collected to show that difficult and protracted birth does in fact coincide with the development of a neurosis, or even that children so born exhibit early infantile apprehensiveness more strongly and over a longer period than other children. It might be rejoined that pre-

cipitate labour and birth, that are easy for the mother quite possibly involve a severe trauma for the child. But we can still point out that births which lead to asphyxia would be bound to give clear evidence of the results which are supposed to follow. It should be one of the advantages of Rank's aetiological theory that it postulates a factor whose existence can be verified by observation. And so long as no such attempt at verification has been made it is impossible to assess the value of that theory.

On the other hand, I cannot identify myself with the view that Rank's theory contradicts the aetiological importance of the sexual instincts as hitherto recognized by psycho-analysis. For his theory only has reference to the position of the individual in regard to the danger-situation, so that it leaves it perfectly open to us to assume that, if a person has not been able to master his first dangers, he is bound to succumb to later situations involving sexual dangers and thus be driven into a neurosis.

I do not believe, therefore, that Rank's attempt has solved the problem of the causation of neurosis; nor do I believe that we can say as yet how much it may have contributed to such a solution. If an investigation into the effects of difficult birth upon the predisposition to neurosis should yield negative results, we shall rate the value of his contribution low. It is to be feared that our endeavours to find a single, tangible *ultimate cause* of neurotic illness will go unrewarded. The ideal solution, which the medical man no doubt still yearns for, would be to discover some bacillus which could be isolated and bred in a pure culture and which, when injected into a person, would invariably produce the same illness; or, to put it somewhat less fantastically, to demonstrate the existence of certain chemical substances the administration of which would create or abolish particular neuroses. But the probability of a solution of this kind seems slight.

Psycho-analysis leads to less simple and satisfactory conclusions. What I have to say in this connection is already long since known and contains nothing new. If the ego succeeds in protecting itself from a dangerous instinctual impulse, through, say, the process of repression, it has certainly inhibited and damaged the particular part of the id concerned; but it has at the same time given it a bit of independence and has renounced a bit of its own sovereignty. This is inevitable from the nature of repression, which is, fundamentally, an at-

tempt at flight. The repressed is now, as it were, outlawed; it is excluded from the great organization of the ego and is only subject to the laws which govern the realm of the unconscious. If, now, the danger-situation changes so that the ego has no reason for warding off a new instinctual impulse which resembles the repressed one, the consequence of the restriction of the ego which has taken place will become manifest. The new impulse will run its course under an automatic influence—or, as I should prefer to say, under the influence of the repetition-compulsion. It will follow the same path as the earlier, repressed impulse, as though the danger-situation that had been overcome still existed. The fixating factor in repression, then, is the repetition-compulsion of the unconscious id—a compulsion which in normal circumstances is only done away with by the mobile function of the ego. The ego may occasionally manage to break down the barriers of repression which it has itself put up and to recover its influence over the instinctual impulse and direct its course in accordance with the changed danger-situation. But in point of fact the ego very seldom succeeds in doing this: it cannot undo its repressions. It is possible that the way the struggle will go depends upon quantitative relations. In many cases one has the impression that the outcome is an enforced one: the regressive attraction exerted by the repressed impulse and the strength of the repression are so great that the new impulse has no choice but to obey the compulsion to repeat. In other cases the entrance of yet another element into the play of forces may be perceived: the attraction exerted by the repressed instinctual prototype is reinforced by a repulsion brought to bear by objective difficulties which are opposed to the new impulse taking a different course.

That this is the origin of fixation in repression and of the retention of danger-situations which are no longer present-day ones is confirmed by the fact of psycho-analytic therapy—a fact which is modest enough in itself but which can hardly be over-rated from a theoretical point of view. When, in the course of an analysis, we have given the ego assistance and have put it in a position to abolish its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way is in general accord with the therapeutic achievements of medicine; for

as a rule we must be satisfied with bringing about more quickly, more certainly and with less expenditure of energy than would otherwise be the case a desired result which in favourable circumstances would have occurred of itself.

We see from what has been said that it is quantitative relations—relations which are not directly observable but can only be inferred—which determine whether or no old situations of danger shall be preserved, repressions on the part of the ego maintained, and childhood neuroses find continuance. Among the factors that play a part in the causation of neuroses and that have created the conditions under which the forces of the mind are pitted against one another, three emerge into prominence: a biological, a phylogenetic, and a purely psychological factor.

The biological factor is the long period of time during which the young of the human species is in a condition of helplessness and dependence. Its intra-uterine existence seems to be short in comparison with that of most animals, and it is sent into the world in a less finished state. As a result the influence of the objective world upon it is intensified and it is obliged to make an early differentiation between the ego and the id. Moreover, the dangers of the outer world have a greater importance for it, so that the value of the object which can alone protect it against them and take the place of its former intra-uterine life is enormously enhanced. This biological factor, then, establishes the earliest situations of danger and creates the need to be loved which will accompany the child through the rest of its life.

The existence of the second, phylogenetic, factor, is based only upon inference. We have been led to assume its reality by a remarkable feature in the development of the libido. We have found that the sexual life of man, unlike that of most of the animals nearly related to him, does not make a steady advance from birth to maturity, but that, after an early expansion up till the fifth year, it undergoes a very decided interruption; and that it then starts on its course once more at puberty, beginning from the point at which it broke off in early childhood. This has led us to suppose that something momentous must have occurred in the vicissitudes of the human species which has left behind this interruption in the sexual development of the individual as a kind of historical precipitate. This factor owes its pathogenic significance to the fact that the

majority of instinctual impulses belonging to infantile sexuality are treated by the ego as dangers and warded off as such, so that the later sexual impulses of puberty, which in the natural course of things would be ego-syntonic, run the risk of succumbing to the attraction of their infantile prototypes and following them into repression. It is here that we come upon the most direct aetiology of the neuroses. It is a curious thing that early contact with the demands of sexuality should have a similar effect on the ego as premature contact with the external world.

The third, psychological, factor resides in a defect of the mental apparatus which has to do with its differentiation into id and ego, and which is therefore ultimately attributable to the influence of the external world. In view of the dangers of objective reality the ego is obliged to guard against certain instinctual impulses in the id and to treat them as dangers. But it cannot protect itself from internal instinctual dangers as effectively as it can from some bit of objective reality that is not part of itself. Intimately bound up with the id as it is, it can only ward off an instinctual danger by restricting its own organization and by acquiescing in the formation of symptoms in exchange for having impaired the instinct. If the rejected instinct renews its attack, the ego is overtaken by all those difficulties which are known to us as neurotic illness.

Further than this, I believe, our knowledge of the nature and causes of neurosis has not as yet been able to go.

## CHAPTER XI

### APPENDICES

IN the course of this discussion various themes have had to be put aside before they had been fully dealt with. They have been brought together in this chapter in order to receive the attention they deserve.

#### *A. Modifications of Earlier Views*

##### *(a) Resistance and Anti-Cathexis*

An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure of energy. If this expenditure of energy were to cease, the repressed impulse, which is being fed all the time from its sources of energy, would seize the next occasion to flow along the channels from which it has been forced aside, and the repression

would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are incessant in their nature that the ego has to make its defensive action secure by a permanent expenditure of energy. This action undertaken to protect repression is perceptible as *resistance* in analytic treatment. Resistance presupposes the existence of what I have called an *anti-cathexis*. An anti-cathexis of this kind is best seen in obsessional neurosis. It appears in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed, as is seen, for instance, in pity, conscientiousness, and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anti-cathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in many circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict of ambivalence in hysteria, for instance, is resolved by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. An hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not be a more affectionate person than other women or even very fond of children in general. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading over of this kind—a loosening of relations to the object and a great facility of displacement in the choice of object.

There is another kind of anti-cathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception

of an object that it desires. The hysterical anti-cathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of *scotomization*. This technique of anti-cathexis is still more noticeable in the phobias, where interest is concentrated on removing the subject ever further from the possibility of making the feared perception. The fact that anti-cathexis should be orientated in an opposite direction in hysteria and the phobias from what it is in obsessional neurosis—though the difference is not an absolute one—seems to be significant. It suggests that there is an intimate connection between repression and external anti-cathexis on the one hand and between regression and internal anti-cathexis (i.e., alterations in the ego through reaction-formations) on the other. The task of defending against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.

As has already been seen, the resistance that has to be overcome in analysis proceeds from the ego clinging to its anti-cathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it has made its own. Our campaign against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make that resistance conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that, even after the ego has decided to relinquish its resistances, it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of *working through*. The dynamic factor which

makes a working through of this kind necessary and comprehensible is not far to seek. It must be that after the ego-resistance has been removed the power of the repetition-compulsion—the attraction exerted by the unconscious prototypes upon the repressed instinctual process—has yet to be overcome. This factor might well be described as the *resistance of the unconscious*. There is no need to be discouraged by these emendations in our theory. They are to be welcomed if they do something towards furthering our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views—by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

It must not be supposed that these emendations provide us with a complete review of all the varieties of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five varieties of resistance, emanating from three quarters—the ego, the id, and the super-ego. The id and the super-ego supply one variety apiece, while the ego is the source of three, each differing in its dynamic nature. The first of these three ego-resistances is the resistance due to repression, which we have already discussed and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the epinoic gain and is based upon an assimilation of the symptom by the ego. It represents an unwillingness to renounce any gratification or relief that has been obtained. The fourth variety, belonging to the id, is the resistance which, as has just been seen, necessitates *working through*. The fifth, belonging to the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

#### (b) Anxiety from Transformation of Libido

The view of anxiety which I have put for-

ward in these pages differs somewhat from the one I have hitherto held. Formerly I regarded anxiety as a general reaction of the ego to conditions of unpleasure. I always sought to account for its appearance on economic grounds and I assumed, on the strength of my investigations into the actual neuroses, that libido (sexual excitement) which was rejected or not utilized by the ego found direct discharge in the form of anxiety. It cannot be denied that these various assertions did not go very well together, or at any rate did not imply one another. Moreover, they gave the impression of there being a specially intimate connection between anxiety and libido and this did not accord with the general character of anxiety as a reaction to unpleasure.

The objection to this view arose from our coming to regard the ego as the sole seat of anxiety. It was one of the results of the attempt to subdivide the mental apparatus which I made in *The Ego and the Id*. Whereas the old view made it natural to suppose that anxiety arose from the libido belonging to the repressed instinctual impulses, the new one tended to make the ego the source of anxiety. Thus it is a question of id-anxiety (instinctual anxiety) versus ego-anxiety. Since the energy which the ego employed is desexualized, the new view tended to weaken the close connection between anxiety and libido. I hope I have at least succeeded in making the contradiction plain and in giving a clear idea of the point in doubt.

Rank's contention—which was originally my own—that the affect of anxiety is a consequence of the event of birth and a repetition of the situation then experienced, obliged me to review the problem of anxiety once more. But I could make no headway with his idea that birth is a trauma, states of anxiety a reaction of discharge to it, and all subsequent affects of anxiety an attempt to *ab-react* it more and more completely. I was obliged to go beyond the anxiety reaction to the situation of danger that lay behind it. The introduction of this element opened up new aspects of the question. Birth was seen to be the prototype of all later situations of danger which overtook the individual under the new conditions arising from a changed mode of life and a growing mental development. The significance of birth in regard to danger was, however, reduced to its occupying this rôle of a prototype. The anxiety felt at birth became the prototype of an affective state which had to undergo the same vicissitudes as the other affects. Two

things might happen to this affect of anxiety: it might reproduce itself automatically in situations which resembled the original situation and thus be an inexpedient form of reaction instead of an expedient one as it had been in the first situation; or the ego might acquire power over it and reproduce it on its own initiative, and employ it as a warning of danger and as a means of setting the pleasure-unpleasure mechanism in motion. We thus gave the biological aspect of the affect of anxiety its due importance by recognizing anxiety as the general reaction to situations of danger; while we endorsed the part played by the ego as the seat of anxiety by allocating to it the function of producing the affect of anxiety according to its needs. Thus we attributed two sources of origin to anxiety in later life. One was involuntary, automatic, and always due to economic causes and arose whenever a situation analogous to birth had established itself. The other was produced by the ego as soon as a situation of this kind merely threatened to occur, in order that it might be avoided. In the second case the ego subjected itself to anxiety as though to a sort of inoculation, willing to go through a slight attack of the illness in order to escape its full strength. It vividly imagined the danger-situation, as it were, with the unmistakable purpose of restricting the actual painful experience to a mere indication, a signal. We have already seen in detail how the various situations of danger arise one after the other, remaining at the same time connected in their origin.

We shall perhaps be able to proceed a little further in our knowledge of anxiety when we turn to the problem of the relation between neurotic anxiety and objective anxiety.

Our former hypothesis of a direct transformation of libido into anxiety possesses less interest for us now than it did. But if we do nevertheless consider this matter of transformation we shall have to distinguish different cases. As regards anxiety evoked by the ego as a signal, it does not come into consideration; nor does it, therefore, in any of those danger-situations which stimulate the ego to bring on repression. The libidinal cathexis of the repressed instinctual impulse is otherwise employed than in being transformed into anxiety and discharged as such, as is most clearly seen in conversion-hysteria. On the other hand, further enquiry into the question of the danger-situation will bring to our notice an instance of the production of anxiety which will, I think,

have to be accounted for in a different way.

### (c) Repression and Defence

In the course of discussing the problem of anxiety I have revived a concept or, to put it more modestly, a term, of which I made exclusive use thirty years ago when I first began to study the subject but which I later abandoned. I refer to the term *defensive process*.<sup>1</sup> I afterwards used the word *repression*, but the relation between the two remained uncertain. It will be an undoubted advantage, I think, to revert to the old term of *defence*, provided we employ it explicitly as a general designation for all the techniques which the ego makes use of in conflicts which may lead to a neurosis, while we retain the word *repression* for that special method of defence which the line of approach taken by our investigations made us better acquainted with in the first instance.

Even a terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the idea of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and the formation of symptoms were made in connection with hysteria. We found that the perceptual content of excitatory experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we saw that in that illness pathogenic occurrences were not forgotten. They remained conscious; but they were isolated in some way that we could not as yet grasp, so that much the same result was obtained as in hysterical amnesia. Nevertheless, the difference was great enough to justify the belief that the process by which instinctual impulses were set aside in obsessional neurosis could not be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage takes place owing to the opposition of the ego, and that this regression clearly works in the same sense as repression although it does not make repression unnecessary. We have seen,

too, that in obsessional neurosis anti-cathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of *isolation* (whose technique cannot as yet be elucidated) which has direct symptomatic manifestations of its own, and to a procedure, that may be called magical, of *undoing* what has been done—a procedure about whose repudiating purpose there can be no doubt, but which has no longer any resemblance to the process of repression. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all of these processes with their same purpose—namely, the protection of the ego against instinctual demands—and for subsuming repression under it as a special instance. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important relationship. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has attained these levels of organization.

### B. Supplementary Remarks on Anxiety

The affect of anxiety exhibits one or two features the study of which promises to throw further light on the subject. Anxiety has an unmistakable affinity with expectation: it is anxiety *about* something. It has a quality of indefiniteness and lack of object. In precise speech we use the word *fear* rather than *anxiety*, if the feeling has found an object. Moreover, in addition to its relation to danger, anxiety has a relation to neurosis which we have long been trying to elucidate. The question arises: why are not all reactions of anxiety neurotic—why do we accept so many of them as normal? And finally the problem of the difference between objective anxiety and neurotic anxiety awaits a thorough examination.

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with objective anxiety,

<sup>1</sup> Freud, "The Defence Neuro-Psychoses" (1894), see page 81 above.

we shall have no difficulty in solving the question. Objective danger is a danger that is known, and objective anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from objective anxiety, so that it can be dealt with in the same way.

There are two reactions to objective danger. One, an affective reaction, is an outbreak of anxiety. The other is a protective action. The same will presumably be true of instinctual danger. We know how the two reactions can co-operate in an expedient way, the one giving the signal for the other to appear. But they can also behave in an inexpedient way; paralysis due to anxiety may set in, and the one reaction spread at the cost of the other.

In some cases the characteristics of objective anxiety and neurotic anxiety are mingled. The danger is known and objective but the anxiety in regard to it is over-great, greater than seems proper. It is this surplus of anxiety which betrays the presence of a neurotic element. Such cases, however, contain no new principle; for analysis shows that to the known objective danger is attached an unknown instinctual one.

We can find out still more about this if, not content with tracing anxiety back to danger, we go on to enquire what the essence and meaning of a danger-situation is. Clearly, it consists in the subject's estimation of his own strength compared to the magnitude of the danger and in his admission of helplessness in the face of it—physical helplessness if the danger is objective and psychological helplessness if it is instinctual. In doing this he will be guided by the actual experiences he has had. (Whether he is wrong in his estimation or not is immaterial for the outcome.) Let us call a situation of helplessness of this kind that has been actually experienced a *traumatic situation*. We shall then have good grounds for distinguishing a traumatic situation from a danger-situation.

The individual will have made an important advance in his capacity for self-preservation if he can foresee and expect a traumatic situation of this kind entailing helplessness instead of simply waiting for it to happen. Let us call a situation which contains the determinant for an expectation of this kind a *danger-situation*. It is in this situation that the signal of anxiety

is made. The signal announces: "I am expecting a situation of helplessness to set in," or: "The present situation reminds me of one of the traumatic experiences I have had before. Therefore I will anticipate the trauma and behave as though it had already come, while there is yet time to turn it aside." Anxiety is, therefore, on the one hand an expectation of a trauma, and on the other a repetition of it in a mitigated form. Thus the two features of anxiety which we have noted have a different origin. Its connection with expectation belongs to the danger-situation, whereas its indefiniteness and lack of object belong to the traumatic situation of helplessness—the situation which is anticipated in the danger-situation.

Taking this sequence—*anxiety-danger-helplessness (trauma)*—we can now summarize what has been said. A danger-situation is a recognized, remembered, and expected situation of helplessness. Anxiety is the original reaction to helplessness in the trauma and is reproduced later on in the danger-situation as a signal for help. The ego, which has undergone the trauma passively, now repeats it actively in a weakened version, hoping to have the direction of it in its own hands. It is certain that children behave in this fashion towards every painful impression they receive, by reproducing it in their play. In thus changing from passivity to activity they attempt to master it psychologically. If this is what is meant by *ab-reacting a trauma*, we can have nothing to urge against the phrase. But what is of decisive importance is the first displacement of the anxiety reaction from its origin in the situation of helplessness to an expectation of that situation, that is, to the danger-situation. After that come the later displacements, from the danger to the determinant of the danger—loss of the object and the modifications of that loss with which we are already acquainted.

The undesirable result of *spoiling* the small child is to increase the importance of the danger of losing the object (the object being a protection against every situation of helplessness) in comparison with every other danger. It therefore encourages the individual to remain in the state of childhood, the period of life which is characterized by motor and mental helplessness.

So far we have had no occasion to regard objective anxiety in any different light from neurotic anxiety. We know what the distinction is. An objective danger is a danger which threatens a person from an external object,

and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something objective, his neurotic anxiety, too, can be admitted to have an objective basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external objective danger, but that this line of defensive activity eventuates in a neurosis, owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its gratification would bring on an external danger, i.e., because the internal danger represents an external one.

On the other hand, the external (objective) danger must have managed to become internalized if it is to be significant for the ego. It must have been recognized as related to some situation of helplessness that has been experienced.<sup>1</sup> Man does not seem to have been endowed, or has been endowed, in but small measure, with an instinctive recognition of the dangers that threaten him from without. Small children are constantly doing things which endanger their lives, and that is precisely why they cannot afford to be without a protecting object. With regard to the traumatic situation, in which the subject is helpless, external and internal dangers, objective dangers, and instinctual demands converge. Whether the ego is suffering from a pain which will not stop or experiencing an accumulation of instinctual needs which cannot obtain gratification, the economic situation is the same and the motor helplessness of the ego finds expression in psychological helplessness.

In this connection, the puzzling question of the phobias of early childhood deserves to be mentioned once again. Some of them, such as the fear of being alone or in the dark or with strangers, can be understood as reactions to the danger of losing the object. Others, like the fear of small animals, thunderstorms, etc.,

might perhaps be accounted for as vestigial traces of the congenital preparedness to meet objective dangers which is so strongly developed in other animals. In man only that part of this archaic inheritance is appropriate which has reference to the loss of object. If his childhood phobias become fixated and grow stronger and persist into later years, analysis shows that their content has become associated with instinctual demands and has come to stand for internal dangers as well.

### C. Anxiety, Pain, and Mourning

So little is known about the psychology of processes of feeling that the tentative remarks I am about to make on the subject may claim a very lenient judgment. The problem before us arises out of the conclusion we have reached that anxiety comes to be a reaction to the danger of losing the object. Now we already know one reaction to the loss of an object, and that is mourning. The question therefore is: when does loss of object lead to anxiety and when to mourning? In discussing the subject of mourning on a previous occasion<sup>2</sup> I found that there was one feature about it which remained quite unexplained. This was its peculiar painfulness. And yet it somehow seems self-evident that separation from an object should be painful. Thus the problem becomes more complicated: when does separation from an object produce anxiety, when does it produce mourning, and when does it produce, it may be, only pain?

Let me say at once that there is no prospect of answering these questions at present. We must content ourselves with drawing certain distinctions and adumbrating certain possibilities.

Our starting-point will again be the one situation which we believe we understand—the situation of the infant when he is presented with a stranger instead of his mother. He will exhibit the anxiety which we have attributed to the danger of loss of object. But his anxiety is undoubtedly more complicated than this and merits a more thorough discussion. That he does have anxiety there can be no doubt; but the expression of his face and his reaction of crying indicate that he is feeling pain as well. Certain things seem to be confused in him which will later on be separated out. He cannot as yet distinguish between temporary absence and permanent loss. As soon as he misses his mother he behaves as if he were never going to

<sup>1</sup> It may also often happen that, although a danger-situation is correctly estimated in itself, a certain amount of instinctual anxiety is joined on to the objective anxiety. In that case the instinctual demand before whose gratification the ego recoils is a masochistic one: the instinct of destruction directed against the subject himself. Perhaps an addition of this kind explains cases in which reactions of anxiety are exaggerated, ineffectual, or paralyzing. Phobias of heights (windows, towers, precipices, and the like) may have some such origin. Their hidden feminine significance is closely connected with masochism.

<sup>2</sup> "Mourning and Melancholia" (1917), *Collected Papers*, IV.

see her again; and repeated consolatory experiences to the contrary are necessary before he learns that her disappearance is usually followed by her reappearance. His mother encourages this piece of knowledge which is so vital to him by playing the familiar game of hiding her face from him with her hands and then, to his joy, uncovering it again. In these circumstances he can, as it were, feel longing unmixed with despair.

In consequence of the infant's misunderstanding of the facts, the situation of missing his mother is not a danger-situation but a traumatic one. Or, to put it more correctly, it is a traumatic situation if he happens at the time to be feeling a need which she is the one to gratify. It turns into a danger-situation if this need is not present at the moment. Thus, the first determinant of anxiety which the ego itself introduces is loss of perception of the object (which is equated with loss of the object itself). There is as yet no question of loss of love. It is only later on that experience teaches the child that the object can be present but angry with him; and then loss of love on the part of the object becomes a new and much more enduring danger and determinant of anxiety.

The traumatic situation of missing the mother differs in one important respect from the traumatic situation of birth. At birth no object existed and so no object could be missed. Anxiety was the only reaction that occurred. Since then repeated situations of gratification have resulted in setting up the mother as an object; and this object, whenever the infant feels a need, receives an intense cathexis of longing. It is to this new aspect of things that the reaction of pain is referable. Pain is thus the actual reaction to loss of object, and anxiety is the reaction to the danger which that loss entails and, in its further displacement, a reaction to the danger of the loss of object itself.

We know very little about pain either. The only fact we are certain of is that pain occurs in the first instance and as a regular thing whenever a stimulus which impinges on the periphery breaks through the protective barrier against stimuli and proceeds to act like a continual instinctual stimulus, against which muscular action, which is as a rule effective because it withdraws the place that is being stimulated from the stimulus, is powerless. If the pain does not proceed from a part of the skin but from an internal organ the situation is still the same. All that has happened is that a portion of the

inner periphery has taken the place of the outer periphery. The child obviously has occasion to undergo experiences of pain of this sort, which have no relation to its experiences of need. This determinant of the development of pain seems, however, to have very little similarity with the loss of an object. And besides, the element which is essential to pain, peripheral stimulation, is entirely absent in the child's situation of longing. Yet it cannot be for nothing that the common usage of speech should have created the notion of internal mental pain and have treated the feeling of loss of object as equivalent to physical pain.

When there is physical pain, a high degree of what may be termed *narcissistic cathexis of the painful place* occurs. This cathexis continues to increase and tends, as it were, to empty the ego. It is well known that, when internal organs are giving pain, spatial and other images of the affected part of the body arise, though that part is not represented in conscious ideation on other occasions. Again, the remarkable truth that when the mind is diverted to some other interest by psychological means even the most intense physical pains fail to arise (I must not say "remain unconscious" in this case) can be accounted for by the fact that there is a concentration of cathexis on the psychical representative of the part of the body which is giving pain. I think it is here that we shall find the point of analogy which has enabled us to carry sensations of pain over to the mental sphere. For the economic conditions that are produced by the intense cathexis of longing which is concentrated on the missed or lost object (a cathexis which steadily mounts up because it cannot be appeased) are the same as the economic conditions that are produced by the cathexis of pain which is concentrated on the injured part of the body. Thus the element of the peripheral causation of physical pain can be left out of account. The transition from physical pain to mental pain corresponds to a change from narcissistic cathexis to object-cathexis. The object whose presentation is highly cathected by instinctual need plays the same rôle as the part of the body which is cathected by an increase of stimulus. The continuous nature of the cathectic process and the impossibility of inhibiting it produce the same state of mental helplessness. If the feeling of unpleasure which thus arises has the specific quality of pain (a quality which cannot be more exactly described) instead of manifesting itself in the reactive form of anxiety,

this may very likely be due to a certain factor which we have not sufficiently made use of in our explanatory efforts. I refer to the high level of cathexis and attachment at which the unpleasurable processes we have been discussing take place.

We know of yet another reaction of feeling to the loss of an object, and that is mourning. But we have no longer any difficulty in accounting for it. Mourning occurs under the influence of reality-testing; for the latter function demands categorically from the bereaved per-

son that he should separate himself from the object, since it no longer exists. Mourning is entrusted with the task of carrying out this retreat from the object in all those situations in which it was the recipient of a high degree of cathexis. That this separation should be painful fits in with what we have just said, in view of the high degree and insatiable nature of the cathexis of longing which is concentrated on the object by the bereaved person during the reproduction of the situations in which he must undo the ties that attach him to it.

# Thoughts for the Times on War and Death<sup>1</sup>

## I. THE DISILLUSIONMENT OF THE WAR

SWEPT as we are into the vortex of this war-time, our information one-sided, ourselves too near to focus the mighty transformations which have already taken place or are beginning to take place, and without a glimmering of the inchoate future, we are incapable of apprehending the significance of the thronging impressions, and know not what value to attach to the judgments we form. We are constrained to believe that never has any event been destructive of so much that is valuable in the commonwealth of humanity, nor so misleading to many of the clearest intelligences, nor so debasing to the highest that we know. Science herself has lost her passionless impartiality; in their deep embitterment, her servants seek for weapons from her with which to contribute towards the defeat of the enemy. The anthropologist is driven to declare the opponent inferior and degenerate; the psychiatrist to publish his diagnosis of the enemy's disease of mind or spirit. But probably our sense of these immediate evils is disproportionately strong, and we are not entitled to compare them with the evils of other times of which we have not undergone the experience.

The individual who is not himself a combatant—and so a wheel in the gigantic machinery of war—feels conscious of disorientation, and of an inhibition in his powers and activities. I believe that he will welcome any indication, however slight, which may enable him to find out what is wrong with himself at least. I propose to distinguish two among the most potent factors in the mental distress felt by non-combatants, against which it is such a heavy task to struggle, and to treat of them here: the disillusionment which this war has evoked; and the altered attitude towards death which this—like every other war—imposes on us.

When I speak of *disillusionment*, everyone at once knows what I mean. One need not be a sentimentalist; one may perceive the biological and psychological necessity of suffering in the economics of human life, and yet condemn

war both in its means and in its aims, and devoutly look forward to the cessation of all wars. True, we have told ourselves that wars can never cease so long as nations live under such widely differing conditions, so long as the value of individual life is in each nation so variously computed, and so long as the animosities which divide them represent such powerful instinctual forces in the mind. And we were prepared to find that wars between the primitive and the civilized peoples, between those races whom a colour-line divides, nay, wars with and among the undeveloped nationalities of Europe or those whose culture has perished—that for a considerable period such wars would occupy mankind. But we permitted ourselves to have other hopes. We had expected the great ruling powers among the white nations upon whom the leadership of the human species has fallen, who were known to have cultivated world-wide interests, to whose creative powers were due our technical advances in the direction of dominating nature, as well as the artistic and scientific acquisitions of the mind—peoples such as these we had expected to succeed in discovering another way of settling misunderstandings and conflicts of interest. Within each of these nations there prevailed high standards of accepted custom for the individual, to which his manner of life was bound to conform if he desired a share in communal privileges. These ordinances, frequently too stringent, exacted a great deal from him, much self-restraint, much renunciation of instinctual gratification. He was especially forbidden to make use of the immense advantages to be gained by the practise of lying and deception in competition with his fellow-men. The civilized state regarded these accepted standards as the basis of its existence; stern were its proceedings when an impious hand was laid upon them; frequent the pronouncement that to subject them even to examination, by a critical intelligence was entirely impracticable. It could be assumed, therefore, that the state itself would respect them, nor would contemplate undertaking any infringement of what it acknowledged as the basis of its own existence. To be sure, it was evident

<sup>1</sup> *Collected Papers*, IV; first published early in 1915 in *Imago*, Vol. V; reprinted in *Sammlung*, 4th Series.

that within these civilized states were mingled remnants of certain other races who were universally unpopular and had therefore been only reluctantly, and even so not to the fullest extent, admitted to participation in the common task of civilization, for which they had shown themselves suitable enough. But the great nations themselves, it might have been supposed, had acquired so much comprehension of their common interests, and enough tolerance for the differences that existed between them, that *foreigner* and *enemy* could no longer, as still in antiquity, be regarded as synonymous.

Relying on this union among the civilized races, countless people have exchanged their native home for a foreign dwelling-place, and made their existence dependent on the conditions of intercourse between friendly nations. But he who was not by stress of circumstances confined to one spot, could also confer upon himself, through all the advantages and attractions of these civilized countries, a new, a wider fatherland, wherein he moved unhindered and unsuspected. In this way he enjoyed the blue sea, and the grey; the beauty of the snow-clad mountains and of the green pasture-lands; the magic of the northern forests and the splendour of the southern vegetation; the emotion inspired by landscapes that recall great historical events, and the silence of nature in her inviolate places. This new fatherland was for him a museum also, filled with all the treasures which the artists among civilized communities had in the successive centuries created and left behind. As he wandered from one gallery to another in this museum, he could appreciate impartially the varied types of perfection that miscegenation, the course of historical events, and the special characteristics of their mother-earth had produced among his more remote compatriots. Here he would find a cool inflexible energy developed to the highest point; there, the gracious art of beautifying existence; elsewhere, the sense of order and fixed law—in short, any and all of the qualities which have made mankind the lords of the earth.

Nor must we forget that each of these citizens of culture had created for himself a personal "Parnassus" and "School of Athens." From among the great thinkers and artists of all nations he had chosen those to whom he conceived himself most deeply indebted for what he had achieved in enjoyment and comprehension of life, and in his veneration had associated them with the immortals of old as well as with the more familiar masters of his own tongue. None

of these great figures had seemed to him alien because he had spoken another language—not the incomparable investigator of the passions of mankind, nor the intoxicated worshipper of beauty, nor the vehement and threatening prophet, nor the subtle mocking satirist; and never did he on this account rebuke himself as a renegade towards his own nation and his beloved mother-tongue.

The enjoyment of this fellowship in civilization was from time to time disturbed by warning voices, which declared that as a result of long-prevailing differences wars were unavoidable, even among the members of a fellowship such as this. We refused to believe it; but if such a war indeed must be, what was our imaginary picture of it? We saw it as an opportunity for demonstrating the progress of mankind in communal feeling since the era when the Greek Amphictyones had proclaimed that no city of the league might be demolished, nor its olive-groves hewn down, nor its water cut off. As a chivalrous crusade, which would limit itself to establishing the superiority of one side in the contest, with the least possible infliction of dire sufferings that could contribute nothing to the decision, and with complete immunity for the wounded who must of necessity withdraw from the contest, as well as for the physicians and nurses who devoted themselves to the task of healing. And of course with the utmost precautions for the non-combatant classes of the population—for women who are debarred from war-work, and for the children who, grown older, should be enemies no longer but friends and co-operators. And again, with preservation of all the international undertakings and institutions in which the mutual civilization of peace-time had been embodied.

Even a war like this would have been productive of horrors and sufferings enough; but it would not have interrupted the development of ethical relations between the greater units of mankind, between the peoples and the states.

Then the war in which we had refused to believe broke out, and brought—disillusionment. Not only is it more sanguinary and more destructive than any war of other days, because of the enormously increased perfection of weapons of attack and defence; but it is at least as cruel, as embittered, as implacable as any that has preceded it. It sets at naught all those restrictions known as International Law, which in peace-time the states had bound themselves to observe; it ignores the prerogatives of the wounded and the medical service, the distinc-

tion between civil and military sections of the population, the claims of private property. It tramples in blind fury on all that comes in its way, as though there were to be no future and no goodwill among men after it has passed. It rends all bonds of fellowship between the contending peoples, and threatens to leave such a legacy of embitterment as will make any renewal of such bonds impossible for a long time to come.

Moreover, it has brought to light the almost unbelievable phenomenon of a mutual comprehension between the civilized nations so slight that the one can turn with hate and loathing upon the other. Nay, more—that one of the great civilized nations is so universally unpopular that the attempt can actually be made to exclude it from the civilized community as *barbaric*, although it long has proved its fitness by the most magnificent co-operation in the work of civilization. We live in the hope that the impartial decision of history will furnish the proof that precisely this nation, this in whose tongue we now write, this for whose victory our dear ones are fighting, was the one which least transgressed the laws of civilization—but at such a time who shall dare present himself as the judge of his own cause?

Nations are in a measure represented by the states which they have formed; these states, by the governments which administer them. The individual in any given nation has in this war a terrible opportunity to convince himself of what would occasionally strike him in peacetime—that the state has forbidden to the individual the practice of wrong-doing, not because it desired to abolish it, but because it desires to monopolize it, like salt and tobacco. The warring state permits itself every such misdeed, every such act of violence, as would disgrace the individual man. It practises not only the accepted stratagems, but also deliberate lying and deception against the enemy; and this, too, in a measure which appears to surpass the usage of former wars. The state exacts the utmost degree of obedience and sacrifice from its citizens, but at the same time treats them as children by maintaining an excess of secrecy, and a censorship of news and expressions of opinion that renders the spirits of those thus intellectually oppressed defenceless against every unfavourable turn of events and every sinister rumour. It absolves itself from the guarantees and contracts it had formed with other states, and makes unabashed confession of its rapacity and lust for power, which the private individ-

ual is then called upon to sanction in the name of patriotism.

Nor may it be objected that the state cannot refrain from wrong-doing, since that would place it at a disadvantage. It is no less disadvantageous, as a general rule, for the individual man to conform to the customs of morality and refrain from brutal and arbitrary conduct; and the state but seldom proves able to indemnify him for the sacrifices it exacts. It cannot be a matter for astonishment, therefore, that this relaxation of all the moral ties between the greater units of mankind should have had a seducing influence on the morality of individuals; for our conscience is not the inflexible judge that ethical teachers are wont to declare it, but in its origin is *dread of the community* and nothing else. When the community has no rebuke to make, there is an end of all suppression of the baser passions, and men perpetrate deeds of cruelty, fraud, treachery, and barbarity so incompatible with their civilization that one would have held them to be impossible.

Well may that civilized cosmopolitan, therefore, of whom I spoke, stand helpless in a world grown strange to him—his all-embracing patrimony disintegrated, the common estates in it laid waste, the fellow-citizens embroiled and debased!

In criticism of his disillusionment, nevertheless, certain things must be said. Strictly speaking, it is not justified, for it consists in the destruction of—an illusion! We welcome illusions because they spare us emotional distress, and enable us instead to indulge in gratification. We must not then complain if now and again they come into conflict with some portion of reality, and are shattered against it.

Two things in this war have evoked our sense of disillusionment: the destitution shown in moral relations externally by the states which in their interior relations pose as the guardians of accepted moral usage, and the brutality in behaviour shown by individuals, whom, as partakers in the highest form of human civilization, one would not have credited with such a thing.

Let us begin with the second point and endeavour to formulate, as succinctly as may be, the point of view which it is proposed to criticize. How do we imagine the process by which an individual attains to a higher plane of morality? The first answer is sure to be: He is good and noble from his very birth, his very earliest beginnings. We need not consider this any further. A second answer will suggest that we are concerned with a developmental process, and

will probably assume that this development consists in eradicating from him the evil human tendencies and, under the influence of education and a civilized environment, replacing them by good ones. From that standpoint it is certainly astonishing that evil should show itself to have such power in those who have been thus nurtured.

But this answer implies the thesis from which we propose to dissent. In reality, there is no such thing as *eradicating* evil tendencies. Psychological—more strictly speaking, psychoanalytic—investigation shows instead that the inmost essence of human nature consists of elemental instincts, which are common to all men and aim at the satisfaction of certain primal needs. These instincts in themselves are neither good nor evil. We but classify them and their manifestations in that fashion, according as they meet the needs and demands of the human community. It is admitted that all those instincts which society condemns as evil—let us take as representatives the selfish and the cruel—are of this primitive type.

These primitive instincts undergo a lengthy process of development before they are allowed to become active in the adult being. They are inhibited, directed towards other aims and departments, become commingled, alter their objects, and are to some extent turned back upon their possessor. Reaction-formations against certain instincts take the deceptive form of a change in content, as though egoism had changed into altruism, or cruelty into pity. These reaction-formations are facilitated by the circumstance that many instincts are manifested almost from the first in pairs of opposites, a very remarkable phenomenon—and one strange to the lay public—which is termed the *ambivalence of feeling*. The most easily observable and comprehensible instance of this is the fact that intense love and intense hatred are so often to be found together in the same person. Psychoanalysis adds that the conflicting feelings not infrequently have the same person for their object.

It is not until all these *vicissitudes to which instincts are subject* have been surmounted that what we call the character of a human being is formed, and this, as we know, can only very inadequately be classified as *good* or *bad*. A human being is seldom altogether good or bad; he is usually *good* in one relation and *bad* in another, or *good* in certain external circumstances and in others decidedly *bad*. It is interesting to learn that the existence of

strong *bad* impulses in infancy is often the actual condition for an unmistakable inclination towards *good* in the adult person. Those who as children have been the most pronounced egoists may well become the most helpful and self-sacrificing members of the community; most of our sentimentalists, friends of humanity, champions of animals, have been evolved from little sadists and animal-tormentors.

The transformation of *bad* instincts is brought about by two co-operating factors, an internal and an external. The internal factor consists in an influence on the bad—say, the egoistic—instincts exercised by erotism, that is, by the human need for love, taken in its widest sense. By the admixture of *erotic* components the egoistic instincts are transmuted into *social* ones. We learn to value being loved as an advantage for which we are willing to sacrifice other advantages. The external factor is the force exercised by upbringing, which advocates the claims of our cultural environment, and this is furthered later by the direct pressure of that civilization by which we are surrounded. Civilization is the fruit of renunciation of instinctual satisfaction, and from each newcomer in turn it exacts the same renunciation. Throughout the life of the individual, there is a constant replacement of the external compulsion by the internal. The influences of civilization cause an ever-increasing transmutation of egoistic trends into altruistic and social ones, and this by an admixture of erotic elements. In the last resort it may be said that every internal compulsion which has been of service in the development of human beings was originally, that is, in the evolution of the human race, nothing but an external one. Those who are born today bring with them as an inherited constitution some degree of a tendency (disposition) towards transmutation of egoistic into social instincts, and this disposition is easily stimulated to achieve that effect. A further measure of this transformation must be accomplished during the life of the individual himself. And so the human being is subject not only to the pressure of his immediate environment, but also to the influence of the cultural development attained by his forefathers.

If we give the name of *cultural adaptability* to a man's personal capacity for transformation of the egoistic impulses under the influence of the erotic, we may further affirm that this adaptability is made up of two parts, one innate and the other acquired through experience, and that the relation of the two to each other and

to that portion of the instinctual life which remains untransformed is a very variable one.

Generally speaking, we are apt to attach too much importance to the innate part, and in addition to this we run the risk of overestimating the general adaptability to civilization in comparison with those instincts which have remained in their primitive state—by which I mean that in this way we are led to regard human nature as *better* than it actually is. For there is, besides, another factor which obscures our judgment and falsifies the issue in too favourable a sense.

The impulses of another person are naturally hidden from our observation. We deduce them from his actions and behaviour, which we trace to motives born of his instinctual life. Such a conclusion is bound to be, in many cases, erroneous. This or that action which is *good* from the civilized point of view may in one instance be born of a *noble* motive, in another not so. Ethical theorists class as *good* actions only those which are the outcome of good impulses; to the others they refuse their recognition. But society, which is practical in its aims, is little troubled on the whole by this distinction; it is content if a man regulates his behaviour and actions by the precepts of civilization, and is little concerned with his motives.

We have seen that the external compulsion exercised on a human being by his upbringing and environment produces a further transformation towards good in his instinctual life—a turning from egotism towards altruism. But this is not the regular or necessary effect of the external compulsion. Education and environment offer benefits not only in the way of love, but also employ another kind of premium system, namely, reward and punishment. In this way their effect may turn out to be that he who is subjected to their influence will choose to “behave well” in the civilized sense of the phrase, although no ennoblement of instinct, no transformation of egoistic into altruistic inclinations, has taken place within. The result will, roughly speaking, be the same; only a particular concatenation of circumstances will reveal that one man always acts rightly because his instinctual inclination compels him so to do, and the other is *good* only in so far and for so long as such civilized behaviour is advantageous for his own egoistic purposes. But superficial acquaintance with an individual will not enable us to distinguish between the two cases, and we are certainly misled by our optimism into grossly exaggerating the number

of human beings who have been transformed in a civilized sense.

Civilized society, which exacts good conduct and does not trouble itself about the impulses underlying it, has thus won over to obedience a great many people who are not thereby following the dictates of their own natures. Encouraged by this success, society has suffered itself to be led into straining the moral standard to the highest possible point, and thus it has forced its members into a yet greater estrangement from their instinctual dispositions. They are consequently subjected to an unceasing suppression of instinct, the resulting strain of which betrays itself in the most remarkable phenomena of reaction and compensation formations. In the domain of sexuality, where such suppression is most difficult to enforce, the result is seen in the reaction-phenomena of neurotic disorders. Elsewhere the pressure of civilization brings in its train no pathological results, but is shown in malformations of character, and in the perpetual readiness of the inhibited instincts to break through to gratification at any suitable opportunity. Anyone thus compelled to act continually in the sense of precepts which are not the expression of instinctual inclinations, is living, psychologically speaking, beyond his means, and might objectively be designated a hypocrite, whether this difference be clearly known to him or not. It is undeniable that our contemporary civilization is extraordinarily favourable to the production of this form of hypocrisy. One might venture to say that it is based upon such hypocrisy, and that it would have to submit to far-reaching modifications if people were to undertake to live in accordance with the psychological truth. Thus there are very many more hypocrites than truly civilized persons—indeed, it is a debatable point whether a certain degree of civilized hypocrisy be not indispensable for the maintenance of civilization, because the cultural adaptability so far attained by those living today would perhaps not prove adequate to the task. On the other hand, the maintenance of civilization even on so questionable a basis offers the prospect of each new generation achieving a farther-reaching transmutation of instinct, and becoming the pioneer of a higher form of civilization.

From the foregoing observations, we may already derive this consolation—that our mortification and our grievous disillusionment regarding the uncivilized behaviour of our world-compatriots in this war are shown to be un-

justified. They were based on an illusion to which we had abandoned ourselves. In reality our fellow-citizens have not sunk so low as we feared, because they had never risen so high as we believed. That the greater units of humanity, the peoples and states, have mutually abrogated their moral restraints naturally prompted these individuals to permit themselves relief for a while from the heavy pressure of civilization and to grant a passing satisfaction to the instincts it holds in check. This probably caused no breach in the relative morality within their respective national frontiers.

We may, however, obtain insight deeper than this into the change brought about by the war in our former compatriots, and at the same time receive a warning against doing them an injustice. For the evolution of the mind shows a peculiarity which is present in no other process of development. When a village grows into a town, a child into a man, the village and the child become submerged in the town and the man. Memory alone can trace the earlier features in the new image; in reality the old materials or forms have been superseded and replaced by new ones. It is otherwise with the development of the mind. Here one can describe the state of affairs, which is a quite peculiar one, only by saying that in this case every earlier stage of development persists alongside the later stage which has developed from it; the successive stages condition a co-existence, although it is in reference to the same materials that the whole series of transformations has been fashioned. The earlier mental state may not have manifested itself for years, but none the less it is so far present that it may at any time again become the mode of expression of the forces in the mind, and that exclusively, as though all later developments had been annulled, undone. This extraordinary plasticity of the evolution that takes place in the mind is not unlimited in its scope; it might be described as a special capacity for retroversion—for regression—since it may well happen that a later and higher stage of evolution, once abandoned, cannot be reached again. But the primitive stages can always be re-established; the primitive mind is, in the fullest meaning of the word, imperishable.

What are called *mental diseases* inevitably impress the layman with the idea of destruction of the life of mind and soul. In reality, the destruction relates only to later accretions and developments. The essence of mental disease lies in a return to earlier conditions of affective life and functioning. An excellent example of

the plasticity of mental life is afforded by the state of sleep, which every night we desire. Since we have learnt to interpret even absurd and chaotic dreams, we know that whenever we sleep we cast off our hard-won morality like a garment, only to put it on again next morning. This divestiture is naturally unattended by any danger because we are paralysed, condemned to inactivity, by the state of sleep. Only through a dream can we learn of the regression of our emotional life to one of the earliest stages of development. For instance, it is noteworthy that all our dreams are governed by purely egoistic motives. One of my English friends put forward this proposition at a scientific meeting in America, whereupon a lady who was present remarked that that might be the case in Austria, but she could maintain for herself and her friends that *they* were altruistic even in their dreams. My friend, although himself of English race, was obliged to contradict the lady emphatically on the ground of his personal experience in dream-analysis, and to declare that in their dreams high-minded American ladies were quite as egoistical as the Austrians.

Thus the transformations of instinct, on which our cultural adaptability is based, may also be permanently or temporarily undone by the experiences of life. Undoubtedly the influences of war are among the forces that can bring about such regression; therefore we need not deny adaptability for culture to all who are at the present time displaying uncivilized behaviour, and we may anticipate that the refinement of their instincts will be restored in times of peace.

There is, however, another symptom in our world-compatriots which has perhaps astonished and shocked us no less than the descent from their ethical nobility which has so greatly distressed us. I mean the narrow-mindedness shown by the best intellects, their obduracy, their inaccessibility to the most forcible arguments, their uncritical credulity for the most disputable assertions. This indeed presents a lamentable picture, and I wish to say emphatically that in this I am by no means a blind partisan who finds all the intellectual shortcomings on one side. But this phenomenon is much easier to account for and much less disquieting than that which we have just considered. Students of human nature and philosophers have long taught us that we are mistaken in regarding our intelligence as an independent force and in overlooking its depend-

ence upon the emotional life. Our intelligence, they teach us, can function reliably only when it is removed from the influences of strong emotional impulses; otherwise it behaves merely as an instrument of the will and delivers the inference which the will requires. Thus, in their view, logical arguments are impotent against affective interests, and that is why reasons, which in Falstaff's phrase are "as plenty as blackberries," produce so few victories in the conflict with interests. Psycho-analytic experience has, if possible, further confirmed this statement. It daily shows that the shrewdest persons will all of a sudden behave like imbeciles as soon as the needful insight is confronted by an emotional resistance, but will completely regain their wonted acuity once that resistance has been overcome. The logical infatuations into which this war has deluded our fellow-citizens, many of them the best of their kind, are therefore a secondary phenomenon, a consequence of emotional excitement, and are destined, we may hope, to disappear with it.

Having in this way come to understand once more our fellow-citizens who are now so greatly alienated from us, we shall the more easily endure the disillusionment which the nations, those greater units of the human race, have caused us, for we shall perceive that the demands we make upon them ought to be far more modest. Perhaps they are reproducing the course of individual evolution, and still today represent very primitive phases in the organization and formation of higher unities. It is in agreement with this that the educative factor of an external compulsion towards morality, which we found to be so effective for the individual, is barely discernible in them. True, we had hoped that the extensive community of interests established by commerce and production would constitute the germ of such a compulsion, but it would seem that nations still obey their immediate passions far more readily than their interests. Their interests serve them, at most, as rationalizations for their passions; they parade their interests as their justification for satisfying their passions. Actually why the national units should disdain, detest, abhor one another, and that even when they are at peace, is indeed a mystery. I cannot tell why it is. It is just as though when it becomes a question of a number of people, not to say millions, all individual moral acquirements were obliterated, and only the most primitive, the oldest, the crudest mental at-

titudes were left. Possibly only future stages in development will be able in any way to alter this regrettable state of affairs. But a little more truthfulness and upright dealing on all sides, both in the personal relations of men to one another and between them and those who govern them, should also do something towards smoothing the way for this transformation.

## II. OUR ATTITUDE TOWARDS DEATH

The second factor to which I attribute our present sense of estrangement in this once lovely and congenial world is the disturbance that has taken place in our attitude towards death, an attribute to which hitherto we have clung so fast.

This attitude was far from straightforward. We were of course prepared to maintain that death was the necessary outcome of life, that everyone owes a debt to Nature and must expect to pay the reckoning—in short, that death was natural, undeniable, and unavoidable. In reality, however, we were accustomed to behave as if it were otherwise. We displayed an unmistakable tendency to "shelve" death, to eliminate it from life. We tried to hush it up; indeed we even have the saying, "To think of something as we think of death."<sup>1</sup> That is our own death, of course. Our own death is indeed unimaginable, and whenever we make the attempt to imagine it we can perceive that we really survive as spectators. Hence the psycho-analytic school could venture on the assertion that at bottom no one believes in his own death, or to put the same thing in another way, in the unconscious every one of us is convinced of his own immortality.

As to the death of another, the civilized man will carefully avoid speaking of such a possibility in the hearing of the person concerned. Children alone disregard this restriction; unabashed, they threaten one another with the eventuality of death, and even go so far as to talk of it before one whom they love, as for instance: "Dear Mamma, it will be a pity when you are dead, but then I shall do this or that." The civilized adult can hardly even entertain the thought of another's death without seeming to himself hard or evil-hearted; unless, of course, as a physician, lawyer or something of the sort, he has to deal with death professionally. Least of all will he permit himself to think of the death of another if with that event some gain to himself in freedom, means, or position

<sup>1</sup> The German saying is used as an equivalent for *incredible or unlikely*.—TR.

is connected. This sensitiveness of ours is, of course, impotent to arrest the hand of death; when it has fallen, we are always deeply affected, as if we were prostrated by the overthrow of our expectations. Our habit is to lay stress on the fortuitous causation of the death—accident, disease, infection, advanced age; in this way we betray our endeavour to modify the significance of death from a necessity to an accident. A multitude of simultaneous deaths appears to us exceedingly terrible. Towards the dead person himself we take up a special attitude, something like admiration for one who has accomplished a very difficult task. We suspend criticism of him, overlook his possible misdoings, issue the command: *De mortuis nil nisi bene*,<sup>1</sup> and regard it as justifiable to set forth in the funeral-oration and upon the tombstone only that which is most favourable to his memory. Consideration for the dead, who no longer need it, is dearer to us than the truth, and certainly, for most of us, is dearer also than consideration for the living.

The culmination of this conventional attitude towards death among civilized persons is seen in our complete collapse when death has fallen on some person whom we love—a parent or a partner in marriage, a brother or sister, a child, a dear friend. Our hopes, our pride, our happiness, lie in the grave with him, we will not be consoled, we will not fill the loved one's place. We behave then as if we belonged to the tribe of the Asra, who must die too when those die whom they love.

But this attitude of ours towards death has a powerful effect upon our lives. Life is impoverished, it loses in interest, when the highest stake in the game of living, life itself, may not be risked. It becomes as flat, as superficial, as one of those American flirtations in which it is from the first understood that nothing is to happen, contrasted with a Continental love-affair in which both partners must constantly bear in mind the serious consequences. Our ties of affection, the unbearable intensity of our grief, make us disinclined to court danger for ourselves and for those who belong to us. We dare not contemplate a great many undertakings which are dangerous but quite indispensable, such as attempts at mechanical flight, expeditions to far countries, experiments with explosive substances. We are paralysed by the thought of who is to replace the son with his mother, the husband with his wife, the father with his children, if there should come dis-

aster. The tendency to exclude death from our calculations brings in its train a number of other renunciations and exclusions. And yet the motto of the Hanseatic League declared: "*Navigare necesse est, vivere non necesse*"! (It is necessary to sail the seas, it is not necessary to live.)

It is an inevitable result of all this that we should seek in the world of fiction, of general literature, and of the theatre compensation for the impoverishment of life. There we still find people who know how to die, indeed, who are even capable of killing someone else. There alone, too, we can enjoy the condition which makes it possible for us to reconcile ourselves with death—namely, that behind all the vicissitudes of life we preserve our existence intact. For it is indeed too sad that in life it should be as it is in chess, when one false move may lose us the game, but with the difference that we can have no second game, no return-match. In the realm of fiction we discover that plurality of lives for which we crave. We die in the person of a given hero, yet we survive him, and are ready to die again with the next hero just as easily.

It is evident that the war is bound to sweep away this conventional treatment of death. Death will no longer be denied; we are forced to believe in him. People really are dying, and now not one by one, but many at a time, often ten thousand in a single day. Nor is it any longer an accident. To be sure, it still seems a matter of chance whether a particular bullet hits this man or that; but the survivor may easily be hit by another bullet; and the accumulation puts an end to the impression of accident. Life has, in truth, become interesting again; it has regained its full significance.

Here a distinction should be made between two groups—those who personally risk their lives in battle, and those who have remained at home and have only to wait for the loss of their dear ones by wounds, disease, or infection. It would indeed be very interesting to study the changes in the psychology of the combatants, but I know too little about it. We must stop short at the second group, to which we ourselves belong. I have said already that in my opinion the bewilderment and the paralysis of energies, now so generally felt by us, are essentially determined in part by the circumstance that we cannot maintain our former attitude towards death, and have not yet discovered a new one. Perhaps it will assist us to do this if

<sup>1</sup> Say nothing but good of the dead.—Ed.

we direct our psychological inquiry towards two other relations with death—the one which we may ascribe to primitive, prehistoric peoples, and that other which in every one of us still exists, but which conceals itself, invisible to consciousness, in the deepest-lying strata of our mental life.

The attitude of prehistoric man towards death is known to us, of course, only by inferences and reconstruction, but I believe that these processes have furnished us with tolerably trustworthy information.

Primitive man assumed a very remarkable attitude towards death. It was far from consistent, was indeed extremely contradictory. On the one hand, he took death seriously, recognized it as the termination of life and used it to that end; on the other hand, he also denied death, reduced it to nothingness. This contradiction arose from the circumstance that he took up radically different attitudes towards the death of another man, of a stranger, of an enemy, and towards his own. The death of the other man he had no objection to; it meant the annihilation of a creature hated, and primitive man had no scruples against bringing it about. He was, in truth, a very violent being, more cruel and more malign than other animals. He liked to kill, and killed as a matter of course. That instinct which is said to restrain the other animals from killing and devouring their own species we need not attribute to him.

Hence the primitive history of mankind is filled with murder. Even today, the history of the world which our children learn in school is essentially a series of race-murders. The obscure sense of guilt which has been common to man since prehistoric times, and which in many religions has been condensed into the doctrine of original sin, is probably the outcome of a blood-guiltiness incurred by primitive man. In my book *Totem and Taboo* (1913) I have, following clues given by W. Robertson Smith, Atkinson, and Charles Darwin, attempted to surmise the nature of this primal guilt, and I think that even the contemporary Christian doctrine enables us to deduce it. If the Son of God was obliged to sacrifice his life to redeem mankind from original sin, then by the law of the talion, the requital of like for like, that sin must have been a killing, a murder. Nothing else could call for the sacrifice of a life in expiation. And if the original sin was an offence against God the Father, the primal crime of mankind must have been a parricide, the killing of the primal father of the primitive human

horde, whose image in memory was later transfigured into a deity.<sup>1</sup>

His own death was for primitive man certainly just as unimaginable and unreal as it is for any one of us today. But there was for him a case in which the two opposite attitudes towards death came into conflict and joined issue; and this case was momentous and productive of far-reaching results. It occurred when primitive man saw someone who belonged to him die—his wife, his child, his friend, whom assuredly he loved as we love ours, for love cannot be much younger than the lust to kill. Then, in his pain, he had to learn that one can indeed die oneself, an admission against which his whole being revolted; for each of these loved ones was, in very truth, a part of his own beloved ego. But even so, on the other hand, such deaths had a rightfulness for him, since in each of the loved persons something of the hostile stranger had resided. The law of ambivalence of feeling, which to this day governs our emotional relations with those whom we love most, had assuredly a very much wider validity in primitive periods. Thus these beloved dead had also been enemies and strangers who had aroused in him a measure of hostile feeling.<sup>2</sup>

Philosophers have declared that the intellectual enigma presented to primitive man by the picture of death was what forced him to reflection, and thus that it became the starting-point of all speculation. I believe that here the philosophers think too philosophically, and give too little consideration to the primarily effective motives. I would therefore limit and correct this assertion: By the body of his slain enemy, primitive man would have triumphed, without racking his brains about the enigma of life and death. Not the intellectual enigma, and not every death, but the conflict of feeling at the death of loved, yet withal alien and hated persons was what disengaged the spirit of inquiry in man. Of this conflict of feeling, psychology was the direct offspring. Man could no longer keep death at a distance, for he had tasted of it in his grief for the dead; but still he did not consent entirely to acknowledge it, for he could not conceive of himself as dead. So he devised a compromise; he conceded the fact of death, even his own death, but denied it the significance of annihilation, which he had had no motive for contesting where the death of his enemy had been concerned. During his contemplation of his loved

<sup>1</sup> See "The Infantile Recurrence of Totemism," *Totem and Taboo*.

<sup>2</sup> See "Taboo and the Ambivalence of Emotions," *Totem and Taboo*.

one's corpse he invented ghosts, and it was his sense of guilt at the satisfaction mingled with his sorrow that turned these new-born spirits into evil, dreaded demons. The changes wrought by death suggested to him the disjunction of the individuality into a body and a soul—first of all into several souls; in this way his train of thought ran parallel with the process of disintegration which sets in with death. The enduring remembrance of the dead became the basis for assuming other modes of existence, gave him the conception of life continued after apparent death.

These subsequent modes of existence were at first no more than appendages to that life which death had brought to a close—shadowy, empty of content, and until later times but slightly valued; they showed as yet a pathetic inadequacy. We may recall the answer made to Odysseus by the soul of Achilles:

*Erst in the life on the earth, no less than a god  
we revered thee,  
We the Achaeans; and now in the realm of the  
dead as a monarch  
Here dost thou rule; then why should death  
thus grieve thee, Achilles?  
Thus did I speak: forthwith then answering  
thus he addressed me,  
Speak not smoothly of death, I beseech, O fa-  
mous Odysseus,  
Better by far to remain on the earth as the  
thrall of another;  
E'en of a portionless man that hath means  
right scanty of living,  
Rather than reign sole king in the realm of the  
bodiless phantoms.<sup>1</sup>*

Or in the powerful, bitterly burlesque rendering by Heine, where he makes Achilles say that the most insignificant little Philistine at Stuckert-on-the-Neckar, in being alive, is far happier than he, the son of Peleus, the dead hero, the prince of shadows in the nether world.

It was not until much later that the different religions devised the view of this after-life as the more desirable, the truly valid one, and degraded the life which is ended by death to a mere preparation. It was then but consistent to extend life backward into the past, to conceive of former existences, transmigrations of the soul and reincarnation, all with the purpose of depriving death of its meaning as the termination of life. So early did the denial of death, which above we designated a convention of civilization, actually originate.

<sup>1</sup> *Odyssey*, XI, 484-491; translated by H. B. Cotterill.

Beside the corpse of the beloved were generated not only the idea of the soul, the belief in immortality, and a great part of man's deep-rooted sense of guilt, but also the earliest inkling of ethical law. The first and most portentous prohibition of the awakening conscience was: Thou shalt not kill. It was born of the reaction against that hate-gratification which lurked behind the grief for the loved dead, and was gradually extended to unloved strangers and finally even to enemies.

This final extension is no longer experienced by civilized man. When the frenzied conflict of this war shall have been decided, every one of the victorious warriors will joyfully return to his home, his wife and his children, undelayed and undisturbed by any thought of the enemy he has slain either at close quarters or by distant weapons of destruction. It is worthy of note that such primitive races as still inhabit the earth, who are undoubtedly closer than we to primitive man, act differently in this respect, or did so act until they came under the influence of our civilization. The savage—Australian, Bushman, Tierra del Fuegan—is by no means a remorseless murderer; when he returns victorious from the war-path he may not set foot in his village nor touch his wife until he has atoned for the murders committed in war by penances which are often prolonged and toilsome. This may be presumed, of course, to be the outcome of superstition; the savage still goes in fear of the avenging spirits of the slain. But the spirits of the fallen enemy are nothing but the expression of his own conscience, uneasy on account of his blood-guiltiness; behind this superstition lurks a vein of ethical sensitiveness which has been lost by us civilized men.<sup>2</sup>

Pious souls, who cherish the thought of our remoteness from whatever is evil and base, will be quick to draw from the early appearance and the urgency of the prohibition of murder gratifying conclusions in regard to the force of these ethical stirrings, which must consequently have been implanted in us. Unfortunately this argument proves even more for the opposite contention. So powerful a prohibition can only be directed against an equally powerful impulse. What no human soul desires there is no need to prohibit;<sup>3</sup> it is automatically excluded. The very emphasis of the commandment *Thou shalt not kill* makes it certain that we spring from an endless ancestry of murderers, with

<sup>2</sup> Cf. *Totem and Taboo*.

<sup>3</sup> Cf. the brilliant argument of Frazer quoted in *Totem and Taboo*.

whom the lust for killing was in the blood, as possibly it is to this day with ourselves. The ethical strivings of mankind, of which we need not in the least depreciate the strength and the significance, are an acquisition accompanying evolution; they have then become the hereditary possession of those human beings alive today, though unfortunately only in a very variable measure.

Let us now leave primitive man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which plumbs such depths. We ask what is the attitude of our unconscious towards the problem of death. The answer must be: Almost exactly the same as primitive man's. In this respect, as in many others, the man of prehistoric ages survives unchanged in our unconscious. Thus, our unconscious does not believe in its own death; it behaves as if immortal. What we call our *unconscious* (the deepest strata of our minds, made up of instinctual impulses) knows nothing whatever of negatives or of denials—contradictories coincide in it—and so it knows nothing whatever of our own death, for to that we can give only a negative purport. It follows that no instinct we possess is ready for a belief in death. This is even perhaps the secret of heroism. The rational explanation for heroism is that it consists in the decision that the personal life cannot be so precious as certain abstract general ideals. But more frequent, in my view, is that instinctive and impulsive heroism which knows no such motivation, and flouts danger in the spirit of Anzengruber's Hans the Road-Mender: "Nothing can happen to *me*." Or else that motivation serves but to clear away the hesitation which might delay an heroic reaction in accord with the unconscious. The dread of death, which dominates us oftener than we know, is on the other hand something secondary, being usually the outcome of the sense of guilt.

On the other hand, for strangers and for enemies, we do acknowledge death, and consign them to it quite as readily and unthinkingly as did primitive man. Here there does, indeed, appear a distinction which in practise shows for a decisive one. Our unconscious does not carry out the killing; it merely thinks it and wishes it. But it would be wrong entirely to depreciate this psychical reality as compared with actual reality. It is significant and pregnant enough. In our unconscious we daily and hourly deport all who stand in our way, all who have

offended or injured us. The expression: "Devil take him!" which so frequently comes to our lips in joking anger, and which really means "Death take him!" is in our unconscious an earnest, deliberate death-wish. Indeed, our unconscious will murder even for trifles; like the ancient Athenian law of Draco, it knows no other punishment for crime than death; and this has a certain consistency, for every injury to our almighty and autocratic ego is at bottom a crime of *lèse-majesté*.

And so, if we are to be judged by the wishes in our unconscious, we are, like primitive man, simply a gang of murderers. It is well that all these wishes do not possess the potency which was attributed to them by primitive men;<sup>1</sup> in the cross-fire of mutual maledictions, mankind would long since have perished, the best and wisest of men and the loveliest and fairest of women with the rest.

Psycho-analysis finds little credence among laymen for assertions such as these. They reject them as calumnies which are confuted by conscious experience, and adroitly overlook the faint indications through which the unconscious is apt to betray itself even to consciousness. It is, therefore, relevant to point out that many thinkers who could not have been influenced by psycho-analysis have quite definitely accused our unspoken thoughts of a readiness, heedless of the murder-prohibition, to get rid of anyone who stands in our way. From many examples of this I will choose one very famous one:

In *Le Père Goriot*, Balzac alludes to a passage in the works of J. J. Rousseau where that author asks the reader what he would do if—without leaving Paris and of course without being discovered—he could kill, with great profit to himself, an old mandarin in Peking by a mere act of the will. Rousseau implies that he would not give much for the life of this dignitary. "*Tuer son mandarin*"<sup>2</sup> has passed into a proverb for this secret readiness even on the part of ourselves today.

There is as well a whole array of cynical jests and anecdotes which testify in the same sense, such as, for instance, the remark attributed to a husband: "If one of us dies, I shall go and live in Paris." Such cynical jokes would not be possible unless they contained an unacknowledged verity which could not be countenanced if seriously and baldly expressed. In joke, as we know, even the truth may be told.

<sup>1</sup> See "The Omnipotence of Thought," *Totem and Taboo*.

<sup>2</sup> To kill his mandarin.—ED.

As for primitive man, so also for us in our unconscious, there arises a case in which the two contrasted attitudes towards death, that which acknowledges it as the annihilation of life and the other which denies it as ineffectual to that end, conflict and join issue—and this case is the same as in primitive ages—the death, or the endangered life, of one whom we love, a parent or partner in marriage, a brother or sister, a child or dear friend. These loved ones are on the one hand an inner possession, an ingredient of our personal ego, but on the other hand are partly strangers, even enemies. With the exception of only a very few situations, there adheres to the tenderest and closest of our affections a vestige of hostility which can excite an unconscious death-wish. But this conflict of ambivalence does not now, as it did then, find issue in theories of the soul and of ethics, but in neuroses, which afford us deep insight into normal mental life as well. How often have those physicians who practise psycho-analysis had to deal with the symptom of an exaggeratedly tender care for the well-being of relatives, or with entirely unfounded self-reproaches after the death of a loved person. The study of these cases has left them in no doubt about the extent and the significance of unconscious death-wishes.

The layman feels an extraordinary horror at the possibility of such feelings, and takes this repulsion as a legitimate ground for disbelief in the assertions of psycho-analysis. I think, mistakenly. No depreciation of our love is intended, and none is actually contained in it. It is indeed foreign to our intelligence as also to our feelings thus to couple love and hate, but Nature, by making use of these twin opposites, contrives to keep love ever vigilant and fresh, so as to guard it against the hate which lurks behind it. It might be said that we owe the fairest flowers of our love-life to the reaction against the hostile impulse which we divine in our breasts.

To sum up: Our unconscious is just as in-

accessible to the idea of our own death, as murderously minded towards the stranger, as divided or ambivalent towards the loved, as was man in earliest antiquity. But how far we have moved from this primitive state in our conventionally civilized attitude towards death!

It is easy to see the effect of the impact of war on this duality. It strips us of the later accretions of civilization, and lays bare the primal man in each of us. It constrains us once more to be heroes who cannot believe in their own death; it stamps the alien as the enemy, whose death is to be brought about or desired; it counsels us to rise above the death of those we love. But war is not to be abolished; so long as the conditions of existence among the nations are so varied, and the repulsions between peoples so intense, there will be, must be, wars. The question then arises: Is it not we who must give in, who must adapt ourselves to them? Is it not for us to confess that in our civilized attitude towards death we are once more living psychologically beyond our means, and must reform and give truth its due? Would it not be better to give death the place in actuality and in our thoughts which properly belongs to it, and to yield a little more prominence to that unconscious attitude towards death which we have hitherto so carefully suppressed? This hardly seems indeed a greater achievement, but rather a backward step in more than one direction, a regression; but it has the merit of taking somewhat more into account the true state of affairs, and of making life again more endurable for us. To endure life remains, when all is said, the first duty of all living beings. Illusion can have no value if it makes this more difficult for us.

We remember the old saying: *Si vis pacem, para bellum*. If you desire peace, prepare for war.

It would be timely thus to paraphrase it: *Si vis vitam, para mortem*. If you would endure life, be prepared for death.

# Civilization and Its Discontents

## I

THE impression forces itself upon one that men measure by false standards, that everyone seeks power, success, riches for himself and admires others who attain them, while undervaluing the truly precious things in life. And yet, in making any general judgment of this kind, one is in danger of forgetting the manifold variety of humanity and its mental life. There are certain men from whom their contemporaries do not withhold veneration, although their greatness rests on attributes and achievements which are completely foreign to the aims and ideals of the multitude. One might well be inclined to suppose that after all it is only a minority who appreciate these great men, while the majority cares nothing for them. But the discrepancy between men's opinions and their behaviour is so wide and their desires so many-sided that things are probably not so simple.

One of these exceptional men calls himself my friend in his letters to me. I had sent him my little book which treats of religion as an illusion and he answered that he agreed entirely with my views on religion, but that he was sorry I had not properly appreciated the ultimate source of religious sentiments. This consists in a peculiar feeling, which never leaves him personally, which he finds shared by many others, and which he may suppose millions more also experience. It is a feeling which he would like to call a sensation of *eternity*, a feeling as of something limitless, unbounded, something "oceanic." It is, he says, a purely subjective experience, not an article of belief; it implies no assurance of personal immortality, but it is the source of the religious spirit and is taken hold of by the various Churches and religious systems, directed by them into definite channels, and also, no doubt, used up in them. One may rightly call oneself religious on the ground of this oceanic feeling alone, even though one reject all beliefs and all illusions.

These views, expressed by my friend whom I so greatly honour and who himself once in poetry described the magic of illusion, put me in a difficult position. I cannot discover this "oceanic" feeling in myself. It is not easy to deal scientifically with feelings. One may attempt to describe their physiological signs.

Where that is impossible—I am afraid the oceanic feeling, too, will defy this kind of classification—nothing remains but to turn to the ideational content which most readily associates itself with the feeling. If I have understood my friend aright, he means the same thing as that consolation offered by an original and somewhat unconventional writer to his hero, contemplating suicide: "Out of this world we cannot fall."<sup>1</sup> So it is a feeling of indissoluble connection, of belonging inseparably to the external world as a whole. To me, personally, I may remark, this seems something more in the nature of an intellectual judgment, not, it is true, without any accompanying feeling-tone, but with one of a kind which characterizes other equally far-reaching reflections as well. I could not in my own person convince myself of the primary nature of such a feeling. But I cannot on that account deny that it in fact occurs in other people. One can only wonder whether it has been correctly interpreted and whether it is entitled to be acknowledged as the *fons et origo*<sup>2</sup> of the whole need for religion.

I have nothing to suggest which could effectively settle the solution of this problem. The idea that man should receive intimation of his connection with the surrounding world by a direct feeling which aims from the outset at serving this purpose sounds so strange and is so incongruous with the structure of our psychology that one is justified in attempting a psycho-analytic, that is, genetic explanation of such a feeling. Whereupon the following lines of thought present themselves. Normally there is nothing we are more certain of than the feeling of our self, our own ego. It seems to us an independent unitary thing, sharply outlined against everything else. That this is a deceptive appearance, and that on the contrary the ego extends inwards without any sharp delimitation, into an unconscious mental entity which we call the *id* and to which it forms a façade, was first discovered by psycho-analytic research, and the latter still has much to tell us about the relations of the ego to the *id*. But towards the outer world, at any rate, the ego seems to keep

<sup>1</sup> Christian Grabbe, *Hannibal*: "Ja, aus der Welt werden wir nicht fallen. Wir sind einmal darin."

<sup>2</sup> Source and origin.—Ed.

itself clearly and sharply outlined and delimited. There is only one state of mind in which it fails to do this—an unusual state, it is true, but not one that can be judged as pathological. At its height, the state of being in love threatens to obliterate the boundaries between ego and object. Against all the evidence of his senses, the man in love declares that he and his beloved are one, and is prepared to behave as if it were a fact. A thing that can be temporarily effaced by a physiological function must also of course be liable to disturbance by morbid processes. From pathology we have come to know a large number of states in which the boundary line between ego and outer world become uncertain, or in which they are actually incorrectly perceived—cases in which parts of a man's own body, even component parts of his own mind, perceptions, thoughts, feelings, appear to him alien and not belonging to himself; other cases in which a man ascribes to the external world things that clearly originate in himself, and that ought to be acknowledged by him. So the ego's cognizance of itself is subject to disturbance, and the boundaries between it and the outer world are not immovable.

Further reflection shows that the adult's sense of his own ego cannot have been the same from the beginning. It must have undergone a development, which naturally cannot be demonstrated, but which admits of reconstruction with a fair degree of probability.<sup>1</sup> When the infant at the breast receives stimuli, he cannot as yet distinguish whether they come from his ego or from the outer world. He learns it gradually as the result of various exigencies. It must make the strongest impression on him that many sources of excitation, which later on he will recognize as his own bodily organs, can provide him at any time with sensations, whereas others become temporarily out of his reach—amongst these what he wants most of all, his mother's breast—and reappear only as a result of his cries for help. Thus an *object* first presents itself to the ego as something existing *outside*, which is only induced to appear by a particular act. A further stimulus to the growth and formation of the ego, so that it becomes something more than a bundle of sensations, i.e., recognizes an *outside*, the external world, is afforded by the frequent, unavoidable and manifold pains and unpleasant sensations which the pleasure-principle, still in unre-

stricted domination, bids it abolish or avoid. The tendency arises to dissociate from the ego everything which can give rise to pain, to cast it out and create a pure pleasure-ego, in contrast to a threatening outside, not-self. The limits of this primitive pleasure-ego cannot escape readjustment through experience. Much that the individual wants to retain because it is pleasure-giving is nevertheless part not of the ego but of an object; and much that he wishes to eject because it torments him yet proves to be inseparable from the ego, arising from an inner source. He learns a method by which, through deliberate use of the sensory organs and suitable muscular movements, he can distinguish between internal and external—what is part of the ego and what originates in the outer world—and thus he makes the first step towards the introduction of the reality-principle which is to control his development further. This capacity for distinguishing which he learns of course serves a practical purpose, that of enabling him to defend himself against painful sensations felt by him or threatening him. Against certain painful excitations from within the ego has only the same means of defence as that employed against pain coming from without, and this is the starting-point of important morbid disturbances.

In this way the ego detaches itself from the external world. It is more correct to say: Originally the ego includes everything, later it detaches from itself the external world. The ego-feeling we are aware of now is thus only a shrunken vestige of a far more extensive feeling—a feeling which embraced the universe and expressed an inseparable connection of the ego with the external world. If we may suppose that this primary ego-feeling has been preserved in the minds of many people—to a greater or lesser extent—it would co-exist like a sort of counterpart with the narrower and more sharply outlined ego-feeling of maturity, and the ideational content belonging to it would be precisely the notion of limitless extension and oneness with the universe—the same feeling as that described by my friend as “oceanic.” But have we any right to assume that the original type of feeling survives alongside the later one which has developed from it?

Undoubtedly we have: there is nothing unusual in such a phenomenon, whether in the psychological or in other spheres. Where animals are concerned, we hold the view that the most highly developed have arisen from the

<sup>1</sup> Cf. the considerable volume of work on this topic dating from that of Ferenczi (*Stages in the Development of the Sense of Reality*, 1913) up to Federn's contributions, 1926, 1927 and later.

lowest. Yet we still find all the simple forms alive today. The great saurians are extinct and have made way for the mammals, but a typical representative of them, the crocodile, is still living among us. The analogy may be too remote, and it is also weakened by the fact that the surviving lower species are not as a rule the true ancestors of the present-day more highly developed types. The intermediate members have mostly died out and are known to us only through reconstruction. In the realm of mind, on the other hand, the primitive type is so commonly preserved alongside the transformations which have developed out of it that it is superfluous to give instances in proof of it. When this happens, it is usually the result of a bifurcation in development. One quantitative part of an attitude or an impulse has survived unchanged while another has undergone further development.

This brings us very close to the more general problem of conservation in the mind, which has so far hardly been discussed, but is so interesting and important that we may take the opportunity to pay it some attention, even though its relevance is not immediate. Since the time when we recognized the error of supposing that ordinary forgetting signified destruction or annihilation of the memory-trace, we have been inclined to the opposite view that nothing once formed in the mind could ever perish, that everything survives in some way or other, and is capable under certain conditions of being brought to light again, as, for instance, when regression extends back far enough. One might try to picture to oneself what this assumption signifies by a comparison taken from another field. Let us choose the history of the Eternal City as an example.<sup>1</sup> Historians tell us that the oldest Rome of all was the *Roma quadrata*, a fenced settlement on the Palatine. Then followed the phase of the Septimontium, when the colonies on the different hills united together; then the town which was bounded by the Servian wall; and later still, after all the transformations in the periods of the republic and the early Caesars, the city which the Emperor Aurelian enclosed by his walls. We will not follow the changes the city went through any further, but will ask ourselves what traces of these early stages in its history a visitor to Rome may still find today, if he goes equipped with the most complete historical and topographical knowledge.

Except for a few gaps, he will see the wall of Aurelian almost unchanged. He can find sections of the Servian rampart at certain points where it has been excavated and brought to light. If he knows enough—more than present-day archaeology—he may perhaps trace out in the structure of the town the whole course of this wall and the outline of *Roma quadrata*. Of the buildings which once occupied this ancient ground-plan he will find nothing, or but meagre fragments, for they exist no longer. With the best information about Rome of the republican era, the utmost he could achieve would be to indicate the sites where the temples and public buildings of that period stood. These places are now occupied by ruins, but the ruins are not those of the early buildings themselves but of restorations of them in later times after fires and demolitions. It is hardly necessary to mention that all these remains of ancient Rome are found woven into the fabric of a great metropolis which has arisen in the last few centuries since the Renaissance. There is assuredly much that is ancient still buried in the soil or under the modern buildings of the town. This is the way in which we find antiquities surviving in historic cities like Rome.

Now let us make the fantastic supposition that Rome were not a human dwelling-place, but a mental entity with just as long and varied a past history: that is, in which nothing once constructed had perished, and all the earlier stages of development had survived alongside the latest. This would mean that in Rome the palaces of the Caesars were still standing on the Palatine and the Septizonium of Septimius Severus was still towering to its old height; that the beautiful statues were still standing in the colonnade of the Castle of St. Angelo, as they were up to its siege by the Goths, and so on. But more still: where the Palazzo Caffarelli stands there would also be, without this being removed, the Temple of Jupiter Capitolinus, not merely in its latest form, moreover, as the Romans of the Caesars saw it, but also in its earliest shape, when it still wore an Etruscan design and was adorned with terra-cotta antifixae. Where the Coliseum stands now, we could at the same time admire Nero's Golden House; on the Piazza of the Pantheon we should find out only the Pantheon of today as bequeathed to us by Hadrian, but on the same site also Agrippa's original edifice; indeed, the same ground would support the church of Santa Maria sopra Mi-

<sup>1</sup> According to *The Cambridge Ancient History*, Vol. VII, (1928) "The Founding of Rome," by Hugh Last.

nerva and the old temple over which it was built. And the observer would need merely to shift the focus of his eyes, perhaps, or change his position, in order to call up a view of either the one or the other.

There is clearly no object in spinning this fantasy further; it leads to the inconceivable, or even to absurdities. If we try to represent historical sequence in spatial terms, it can only be done by juxtaposition in space; the same space will not hold two contents. Our attempt seems like an idle game; it has only one justification; it shows us how far away from mastering the idiosyncrasies of mental life we are by treating them in terms of visual representation.

There is one objection, though, to which we must pay attention. It questions our choosing in particular the past history of a *city* to liken to the past of the mind. Even for mental life, our assumption that everything past is preserved holds good only on condition that the organ of the mind remains intact and its structure has not been injured by traumas or inflammation. Destructive influences comparable to these morbid agencies are never lacking in the history of any town, even if it has had a less chequered past than Rome, even if, like London, it has hardly ever been pillaged by an enemy. Demolitions and the erection of new buildings in the place of old occur in cities which have had the most peaceful existence; therefore a town is from the outset unsuited for the comparison I have made of it with a mental organism.

We admit this objection; we will abandon our search for a striking effect of contrast and turn to what is after all a closer object of comparison, the body of an animal or human being. But here, too, we find the same thing. The early stages of development are in no sense still extant; they have been absorbed into the later features for which they supplied the material. The embryo cannot be demonstrated in the adult; the thymus gland of childhood is replaced after puberty by connective tissue but no longer exists itself; in the marrow-bone of a grown man I can, it is true, trace the outline of the childish bone-structure, but this latter no longer survives in itself—it lengthened and thickened until it reached its final form. The fact is that a survival of all the early stages alongside the final form is only possible in the mind, and that it is impossible for us to represent a phenomenon of this kind in visual terms.

Perhaps we are going too far with this con-

clusion. Perhaps we ought to be content with the assertion that what is past in the mind *can* survive and need not necessarily perish. It is always possible that even in the mind much that is old may be so far obliterated or absorbed—whether normally or by way of exception—that it cannot be restored or re-animated by any means, or that survival of it is always connected with certain favourable conditions. It is possible, but we know nothing about it. We can only be sure that it is more the rule than the exception for the past to survive in the mind.

Thus we are entirely willing to acknowledge that the “oceanic” feeling exists in many people, and we are disposed to relate it to an early stage in ego-feeling; the further question then arises: what claim has this feeling to be regarded as the source of the need for religion.

To me this claim does not seem very forcible. Surely a feeling can only be a source of energy when it is itself the expression of a strong need. The derivation of a need for religion from the child’s feeling of helplessness and the longing it evokes for a father seems to me incontrovertible, especially since this feeling is not simply carried on from childhood days but is kept alive perpetually by the fear of what the superior power of fate will bring. I could not point to any need in childhood so strong as that for a father’s protection. Thus the part played by the “oceanic” feeling, which I suppose seeks to reinstate limitless narcissism, cannot possibly take the first place. The derivation of the religious attitude can be followed back in clear outline as far as the child’s feeling of helplessness. There may be something else behind this, but for the present it is wrapped in obscurity.

I can imagine that the “oceanic” feeling could become connected with religion later on. That feeling of oneness with the universe which is its ideational content sounds very like a first attempt at the consolations of religion, like another way taken by the ego of denying the dangers it sees threatening it in the external world. I must again confess that I find it very difficult to work with these intangible quantities. Another friend of mine, whose insatiable scientific curiosity has impelled him to the most out-of-the-way researches and to the acquisition of encyclopaedic knowledge, has assured me that the Yogi by their practices of withdrawal from the world, concentrating attention on bodily functions, peculiar methods of breathing, actually

are able to produce new sensations and diffused feelings in themselves which he regards as regressions to primordial, deeply buried mental states. He sees in them a physiological foundation, so to speak, of much of the wisdom of mysticism. There would be connections to be made here with many obscure modifications of mental life, such as trance and ecstasy. But I am moved to exclaim, in the words of Schiller's diver:

*Who breathes overhead in the rose-tinted  
light may be glad!*

## II

In my *Future of an Illusion*<sup>1</sup> I was concerned much less with the deepest sources of religious feeling than with what the ordinary man understands by his religion, that system of doctrines and pledges that on the one hand explains the riddle of this world to him with an enviable completeness, and on the other assures him that a solicitous Providence is watching over him and will make up to him in a future existence for any shortcomings in this life. The ordinary man cannot imagine this Providence in any other form but that of a greatly exalted father, for only such a one could understand the needs of the sons of men, or be softened by their prayers and placated by the signs of their remorse. The whole thing is so patently infantile, so incongruous with reality, that to one whose attitude to humanity is friendly it is painful to think that the great majority of mortals will never be able to rise above this view of life. It is even more humiliating to discover what a large number of those alive today, who must see that this religion is not tenable, yet try to defend it inch by inch, as if with a series of pitiable rearguard actions. One would like to count oneself among the believers, so as to admonish the philosophers who try to preserve the God of religion by substituting for him an impersonal, shadowy, abstract principle, and say, "Thou shalt not take the name of the Lord thy God in vain!" Some of the great men of the past did the same, but that is no justification for us; we know why they had to do so.

We will now go back to the ordinary man and his religion—the only religion that ought to bear the name. The well-known words of one of our great and wise poets come to mind in which he expresses his view of the relation of religion to art and science. They run:

<sup>1</sup> 1927 (London: Hogarth Press, 1928).

*He who has Science and has Art,  
Religion, too, has he;  
Who has not Science, has not Art,  
Let him religious be!*<sup>2</sup>

On the one hand, these words contrast religion with the two highest achievements of man, and on the other, they declare that in respect of their value in life they can represent or replace each other. If we wish to deprive even the ordinary man, too, of his religion, we shall clearly not have the authority of the poet on our side. We will seek to get in touch with the meaning of his utterance by a special way. Life as we find it is too hard for us; it entails too much pain, too many disappointments, impossible tasks. We cannot do without palliative remedies. We cannot dispense with auxiliary constructions, as Theodor Fontane said. There are perhaps three of these means: powerful diversions of interest, which lead us to care little about our misery; substitutive gratification, which lessen it; and intoxicating substances, which make us insensitive to it. Something of this kind is indispensable.<sup>3</sup> Voltaire is aiming at a diversion of interest when he brings his *Candide* to a close with the advice that people should cultivate their gardens; scientific work is another deflection of the same kind. The substitute gratifications, such as art offers, are illusions in contrast to reality, but none the less satisfying to the mind on that account, thanks to the place which phantasy has reserved for herself in mental life. The intoxicating substances affect our body, alter its chemical processes. It is not so simple to find the place where religion belongs in this series. We must look further afield.

The question, "What is the purpose of human life?" has been asked times without number; it has never received a satisfactory answer; perhaps it does not admit of such an answer. Many a questioner has added that if it should appear that life has no purpose, then it would lose all value for him. But these threats alter nothing. It looks, on the contrary, as though one had a right to dismiss this question, for it seems to presuppose that belief in the superiority of the human race with which we are already so familiar in its other expressions. Nobody asks what is the

<sup>2</sup> Goethe, *Zahmen Xenien* IX (*Gedichte aus dem Nachlass*).

<sup>3</sup> Wilhelm Busch, in *Die fromme Helene*, says the same thing on a lower level: "The man who has cares has brandy too."

purpose of the lives of animals, unless peradventure they are designed to be of service to man. But this, too, will not hold, for with many animals man can do nothing—except describe, classify, and study them; and countless species have declined to be put even to this use, by living and dying and becoming extinct before men had set eyes upon them. So again, only religion is able to answer the question of the purpose of life. One can hardly go wrong in concluding that the idea of a purpose in life stands and falls with the religious system.

We will turn, therefore, to the less ambitious problem: what the behaviour of men themselves reveals as the purpose and object of their lives, what they demand of life and wish to attain in it. The answer to this can hardly be in doubt: they seek happiness, they want to become happy and to remain so. There are two sides to this striving, a positive and a negative; it aims on the one hand at eliminating pain and discomfort, on the other at the experience of intense pleasures. In its narrower sense, the word *happiness* relates only to the last. Thus human activities branch off in two directions—corresponding to this double goal—according to which of the two they aim at realizing, either predominantly or even exclusively.

As we see, it is simply the pleasure-principle which draws up the programme of life's purpose. This principle dominates the operation of the mental apparatus from the very beginning; there can be no doubt about its efficiency, and yet its programme is in conflict with the whole world, with the macrocosm as much as with the microcosm. It simply cannot be put into execution, the whole constitution of things runs counter to it; one might say the intention that man should be *happy* is not included in the scheme of *Creation*. What is called *happiness* in its narrowest sense comes from the satisfaction—most often instantaneous—of pent-up needs which have reached great intensity, and by its very nature can only be a transitory experience. When any condition desired by the pleasure-principle is protracted, it results in a feeling only of mild comfort; we are so constituted that we can only intensely enjoy contrasts, much less intensely states in themselves.<sup>1</sup> Our possibilities of happiness are thus limited from the start

by our very constitution. It is much less difficult to be unhappy. Suffering comes from three quarters: from our own body, which is destined to decay and dissolution, and cannot even dispense with anxiety and pain as danger-signals; from the outer world, which can rage against us with the most powerful and pitiless forces of destruction; and finally from our relations with other men. The unhappiness which has this last origin we find perhaps more painful than any other; we tend to regard it more or less as a gratuitous addition, although it cannot be any less an inevitable fate than the suffering that proceeds from other sources.

It is no wonder if, under the pressure of these possibilities of suffering, humanity is wont to reduce its demands for happiness, just as even the pleasure-principle itself changes into the more accommodating reality-principle under the influence of external environment; if a man thinks himself happy if he has merely escaped unhappiness or weathered trouble; if in general the task of avoiding pain forces that of obtaining pleasure into the background. Reflection shows that there are very different ways of attempting to perform this task; and all these ways have been recommended by the various schools of wisdom in the art of life and put into practice by men. Unbridled gratification of all desires forces itself into the foreground as the most alluring guiding principle in life, but it entails preferring enjoyment to caution and penalizes itself after short indulgence. The other methods, in which avoidance of pain is the main motive, are differentiated according to the source of the suffering against which they are mainly directed. Some of these measures are extreme and some moderate, some are one-sided and some deal with several aspects of the matter at once. Voluntary loneliness, isolation from others, is the readiest safeguard against the unhappiness that may arise out of human relations. We know what this means: the happiness found along this path is that of peace. Against the dreaded outer world one can defend oneself only by turning away in some other direction, if the difficulty is to be solved single-handed. There is indeed another and better way: that of combining with the rest of the human community and taking up the attack on nature, thus forcing it to obey human will, under the guidance of science. One is working, then, with all for the good of all. But the most interesting methods for averting

<sup>1</sup> Goethe even warns us that "nothing is so hard to bear as a train of happy days." This may be an exaggeration all the same.

pain are those which aim in influencing the organism itself. In the last analysis, all pain is but sensation; it only exists in so far as we feel it, and we feel it only in consequence of certain characteristics of our organism.

The crudest of these methods of influencing the body, but also the most effective, is the chemical one: that of intoxication. I do not think anyone entirely understands their operation, but it is a fact that there are certain substances foreign to the body which, when present in the blood or tissues, directly cause us pleasurable sensations, but also so change the conditions of our perceptivity that we become insensible of disagreeable sensations. The two effects not only take place simultaneously, they seem to be closely bound up with each other. But there must be substances in the chemical composition of our bodies which can do the same, for we know of at least one morbid state, that of mania, in which a condition similar to this intoxication arises without any drug being absorbed. Besides this, our normal mental life shows variations, according to which pleasure is experienced with more or less ease, and along with this goes a diminished or increased sensitivity to pain. It is greatly to be regretted that this toxic aspect of mental processes has so far eluded scientific research. The services rendered by intoxicating substances in the struggle for happiness and in warding off misery rank so highly as a benefit that both individuals and races have given them an established position within their libido-economy. It is not merely the immediate gain in pleasure which one owes to them, but also a measure of that independence of the outer world which is so sorely craved. Men know that with the help they can get from "drowning their cares" they can at any time slip away from the oppression of reality and find a refuge in a world of their own where painful feelings do not enter. We are aware that it is just this property which constitutes the danger and injuriousness of intoxicating substances. In certain circumstances they are to blame when valuable energies which could have been used to improve the lot of humanity are uselessly wasted.

The complicated structure of our mental apparatus admits, however, of a whole series of other kinds of influence. The gratification of instincts is happiness, but when the outer world lets us starve, refuses us satisfaction of our needs, they become the cause of very

great suffering. So the hope is born that by influencing these impulses one may escape some measure of suffering. This type of defence against pain no longer relates to the sensory apparatus; it seeks to control the internal sources of our needs themselves. An extreme form of it consists in annihilation of the instincts, as taught by the wisdom of the East and practised by the Yogi. When it succeeds, it is true, it involves giving up all other activities as well (sacrificing the whole of life), and again, by another path, the only happiness it brings is that of peace. The same way is taken when the aim is less extreme and only control of the instincts is sought. When this is so, the higher mental systems which recognize the reality-principle have the upper hand. The aim of gratification is by no means abandoned in this case; a certain degree of protection against suffering is secured, in that lack of satisfaction causes less pain when the instincts are kept in check than when they are unbridled. On the other hand, this brings with it an undeniable reduction in the degree of enjoyment obtainable. The feeling of happiness produced by indulgence of a wild, untamed craving is incomparably more intense than is the satisfying of a curbed desire. The irresistibility of perverted impulses, perhaps the charm of forbidden things generally, may in this way be explained economically.

Another method of guarding against pain is by using the libido-displacements that our mental equipment allows of, by which it gains so greatly in flexibility. The task is then one of transferring the instinctual aims into such directions that they cannot be frustrated by the outer world. Sublimation of the instincts lends an aid in this. Its success is greatest when a man knows how to heighten sufficiently his capacity for obtaining pleasure from mental and intellectual work. Fate has little power against him then. This kind of satisfaction, such as the artist's joy in creation, in embodying his phantasies, or the scientist's in solving problems or discovering truth, has a special quality which we shall certainly one day be able to define metapsychologically. Until then we can only say metaphorically it seems to us *higher* and *finer*, but, compared with that of gratifying gross primitive instincts, its intensity is tempered and diffused; it does not overwhelm us physically. The weak point of this method, however, is that it is not generally applicable; it is only available to the few.

It presupposes special gifts and dispositions which are not very commonly found in a sufficient degree. And even to these few it does not secure complete protection against suffering; it gives no invulnerable armour against the arrows of fate, and it usually fails when a man's own body becomes a source of suffering to him.<sup>1</sup>

This behaviour reveals clearly enough its aim—that of making oneself independent of the external world, by looking for happiness in the inner things of the mind; in the next method the same features are even more marked. The connection with reality is looser still; satisfaction is obtained through illusions, which are recognized as such, without the discrepancy between them and reality being allowed to interfere with the pleasure they give. These illusions are derived from the life of phantasy which, at the time when the sense of reality developed, was expressly exempted from the demands of the reality-test and set apart for the purpose of fulfilling wishes which would be very hard to realize. At the head of these phantasy-pleasures stands the enjoyment of works of art which through the agency of the artist is opened to those who cannot themselves create.<sup>2</sup> Those who are sensitive to the influence of art do not know how to rate it high enough as a source of happiness and consolation in life. Yet art affects us but as a mild narcotic and can provide no more than

<sup>1</sup> When there is no special disposition in a man imperatively prescribing the direction of his life-interest, the ordinary work all can do for a livelihood can play the part which Voltaire wisely advocated it should do in our lives. It is not possible to discuss the significance of work for the economics of the libido adequately within the limits of a short survey. Laying stress upon importance of work has a greater effect than any other technique of living in the direction of binding the individual more closely to reality; in his work he is at least securely attached to a part of reality, the human community. Work is no less valuable for the opportunity it and the human relations connected with it provide for a very considerable discharge of libidinal component impulses, narcissistic, aggressive, and even erotic, than because it is indispensable for subsistence and justifies existence in a society. The daily work of earning a livelihood affords particular satisfaction when it has been selected by free choice, i.e., when through sublimation it enables use to be made of existing inclinations, of instinctual impulses that have retained their strength or are more intense than usual for constitutional reasons. And yet as a path to happiness work is not valued very highly by men. They do not run after it as they do after other opportunities for gratification. The great majority work only when forced by necessity, and this natural human aversion to work gives rise to the most difficult social problems.

<sup>2</sup> Cf. "Formulations regarding the Two Principles in Mental Functioning" (1911), *Collected Papers*, IV; and *General Introduction to Psycho-Analysis* (1915-17), Lecture XXIII, p. 593 above.

a temporary refuge for us from the hardships of life; its influence is not strong enough to make us forget real misery.

Another method operates more energetically and thoroughly; it regards reality as the source of all suffering, as the one and only enemy, with whom life is intolerable and with whom, therefore, all relations must be broken off if one is to be happy in any way at all. The hermit turns his back on this world; he will have nothing to do with it. But one can do more than that; one can try to re-create it, try to build up another instead, from which the most unbearable features are eliminated and replaced by others corresponding to one's own wishes. He who in his despair and defiance sets out on this path will not as a rule get very far; reality will be too strong for him. He becomes a madman and usually finds no one to help him in carrying through his delusion. It is said, however, that each one of us behaves in some respect like the paranoiac, substituting a wish-fulfilment for some aspect of the world which is unbearable to him, and carrying this delusion through into reality. When a large number of people make this attempt together and try to obtain assurance of happiness and protection from suffering by a delusional transformation of reality, it acquires special significance. The religions of humanity, too, must be classified as mass-delusions of this kind. Needless to say, no one who shares a delusion recognizes it as such.

I do not suppose that I have enumerated all the methods by which men strive to win happiness and keep suffering at bay, and I know, too, that the material might have been arranged differently. One of these methods I have not yet mentioned at all—not because I had forgotten it, but because it will interest us in another connection. How would it be possible to forget this way of all others of practising the art of life! It is conspicuous for its remarkable capacity to combine characteristic features. Needless to say, it, too, strives to bring about independence of fate—as we may best call it—and with this object it looks for satisfaction within the mind, and uses the capacity for displacing libido which we mentioned before, but it does not turn away from the outer world; on the contrary, it takes a firm hold of its objects and obtains happiness from an emotional relation to them. Nor is it content to strive for avoidance of pain—that goal of weary resignation;

rather it passes that by heedlessly and holds fast to the deep-rooted, passionate striving for a positive fulfilment of happiness. Perhaps it really comes nearer to this goal than any other method. I am speaking, of course, of that way of life which makes love the centre of all things and anticipates all happiness from loving and being loved. This attitude is familiar enough to all of us; one of the forms in which love manifests itself, sexual love, gives us our most intense experience of an overwhelming pleasurable sensation and so furnishes a prototype for our strivings after happiness. What is more natural than that we should persist in seeking happiness along the path by which we first encountered it? The weak side of this way of living is clearly evident; and were it not for this, no human being would ever have thought of abandoning this path to happiness in favour of any other. We are never so defenceless against suffering as when we love, never so forlornly unhappy as when we have lost our love-object or its love. But this does not complete the story of that way of life which bases happiness on love; there is much more to be said about it.

We may here go on to consider the interesting case in which happiness in life is sought first and foremost in the enjoyment of beauty, wherever it is to be found by our senses and our judgment, the beauty of human forms and movements, of natural objects, of landscapes, of artistic and even scientific creations. As a goal in life, this aesthetic attitude offers little protection against the menace of suffering, but it is able to compensate for a great deal. The enjoyment of beauty produces a particular, mildly intoxicating kind of sensation. There is no very evident use in beauty; the necessity of it for cultural purposes is not apparent, and yet civilization could not do without it. The science of aesthetics investigates the conditions in which things are regarded as beautiful; it can give no explanation of the nature or origin of beauty; as usual, its lack of results is concealed under a flood of resounding and meaningless words. Unfortunately, psycho-analysis, too, has less to say about beauty than about most things. Its derivation from the realms of sexual sensation is all that seems certain; the love of beauty is a perfect example of a feeling with an inhibited aim. *Beauty* and *attraction* are first of all the attributes of a sexual object. It is remarkable that the genitals themselves, the sight of which is always exciting, are

hardly ever regarded as beautiful; the quality of beauty seems, on the other hand, to attach to certain secondary sexual characters.

In spite of the incompleteness of these considerations, I will venture on a few remarks in conclusion of this discussion. The goal towards which the pleasure-principle impels us—of becoming happy—is not attainable; yet we may not—nay, cannot—give up the effort to come nearer to realization of it by some means or other. Very different paths may be taken towards it: some pursue the positive aspect of the aim, attainment of pleasure; others the negative, avoidance of pain. By none of these ways can we achieve all that we desire. In that modified sense in which we have seen it to be attainable, happiness is a problem of the economics of the libido in each individual. There is no sovereign recipe in this matter which suits all; each one must find out for himself by which particular means he may achieve felicity. All kinds of different factors will operate to influence his choice. It depends on how much real gratification he is likely to obtain in the external world, and how far he will find it necessary to make himself independent of it; finally, too, on the belief he has in himself of his power to alter it in accordance with his wishes. Even at this stage the mental constitution of the individual will play a decisive part, aside from any external considerations. The man who is predominantly erotic will choose emotional relationships with others before all else; the narcissistic type, who is more self-sufficient, will seek his essential satisfactions in the inner workings of his own soul; the man of action will never abandon the external world in which he can essay his power. The interests of narcissistic types will be determined by their particular gifts and the degree of instinctual sublimation of which they are capable. When any choice is pursued to an extreme, it penalizes itself, in that it exposes the individual to the dangers accompanying any one exclusive life-interest which may always prove inadequate. Just as a cautious businessman avoids investing all his capital in one concern, so wisdom would probably admonish us also not to anticipate all our happiness from one quarter alone. Success is never certain; it depends on the co-operation of many factors, perhaps on none more than the capacity of the mental constitution to adapt itself to the outer world and then utilize this last for obtaining pleasure. Any one who is born with a specially unfavourable instinctual constitution,

and whose libido-components do not go through the transformation and modification necessary for successful achievement in later life, will find it hard to obtain happiness from his external environment, especially if he is faced with the more difficult tasks. One last possibility of dealing with life remains to such people and it offers them at least substitute-gratifications; it takes the form of the flight into neurotic illness, and they mostly adopt it while they are still young. Those whose efforts to obtain happiness come to nought in later years still find consolation in the pleasure of chronic intoxication, or else they embark upon that despairing attempt at revolt—psychosis.

Religion circumscribes these measures of choice and adaptation by urging upon everyone alike its single way of achieving happiness and guarding against pain. Its method consists in decrying the value of life and promulgating a view of the real world that is distorted like a delusion, and both of these imply a preliminary intimidating influence upon intelligence. At such a cost—by the forcible imposition of mental infantilism and inducing a mass-delusion—religion succeeds in saving many people from individual neuroses. But little more. There are, as we have said, many paths by which the happiness attainable for man can be reached, but none which is certain to take him to it. Nor can religion keep her promises either. When the faithful find themselves reduced in the end to speaking of God's *inscrutable decree*, they thereby avow that all that is left to them in their sufferings is unconditional submission as a last-remaining consolation and source of happiness. And if a man is willing to come to this, he could probably have arrived there by a shorter road.

### III

OUR discussion of happiness has so far not taught us much that is not already common knowledge. Nor does the prospect of discovering anything new seem much greater if we go on with the problem of why it is so hard for mankind to be happy. We gave the answer before, when we cited the three sources of human sufferings, namely, the superior force of nature, the disposition to decay of our bodies, and the inadequacy of our methods of regulating human relations in the family, the community, and the state. In regard to the first two, our judgment cannot hesitate: it forces us to recognize these sources of suffering and to submit to the inevitable. We shall never completely subdue

nature; our body, too, is an organism, itself a part of nature, and will always contain the seeds of dissolution, with its limited power of adaptation and achievement. The effect of this recognition is in no way disheartening; on the contrary, it points out the direction for our efforts. If we cannot abolish all suffering, yet a great deal of it we can, and can mitigate more; the experience of several thousand years has convinced us of this. To the third, the social source of our distresses, we take up a different attitude. We prefer not to regard it as one at all; we cannot see why the systems we have ourselves created should not rather ensure protection and well-being for us all. To be sure, when we consider how unsuccessful our efforts to safeguard against suffering in this particular have proved, the suspicion dawns upon us that a bit of unconquerable nature lurks concealed behind this difficulty as well—in the shape of our own mental constitution.

When we start to consider this possibility, we come across a point of view which is so amazing that we will pause over it. According to it, our so-called civilization itself is to blame for a great part of our misery, and we should be much happier if we were to give it up and go back to primitive conditions. I call this amazing because—however one may define culture—it is undeniable that every means by which we try to guard ourselves against menaces from the several sources of human distress is a part of this same culture.

How has it come about that so many people have adopted this strange attitude of hostility to civilization? In my opinion, it arose from a background of profound long-standing discontent with the existing state of civilization, which finally crystallized into this judgment as a result of certain historical happenings. I believe I can identify the last two of these; I am not learned enough to trace the links in the chain back into the history of the human species. At the time when Christianity conquered the pagan religions, some such antagonism to culture must already have been actively at work. It is closely related to the low estimation put upon earthly life by Christian doctrine. The earlier of the last two historical developments was when, as a result of voyages of discovery, men came into contact with primitive peoples and races. To the Europeans, who failed to observe them carefully and misunderstood what they saw, these people seemed to lead simple, happy lives—wanting for nothing—such as the travellers who visited them, with

all their superior culture, were unable to achieve. Later experience has corrected this opinion on many points; in several instances the ease of life was due to the bounty of nature and the possibilities of ready satisfaction for the great human needs, but it was erroneously attributed to the absence of the complicated conditions of civilization. The last of the two historical events is especially familiar to us; it was when people began to understand the nature of the neuroses which threaten to undermine the modicum of happiness open to civilized man. It was found that men become neurotic because they cannot tolerate the degree of privation that society imposes on them in virtue of its cultural ideals, and it was supposed that a return to greater possibilities of happiness would ensue if these standards were abolished or greatly relaxed.

And there exists an element of disappointment, in addition. In the last generations, man has made extraordinary strides in knowledge of the natural sciences and technical application of them, and has established his dominion over nature in a way never before imagined. The details of this forward progress are universally known: it is unnecessary to enumerate them. Mankind is proud of its exploits and has a right to be. But men are beginning to perceive that all this newly-won power over space and time, this conquest of the forces of nature, this fulfilment of age-old longings, has not increased the amount of pleasure they can obtain in life, has not made them feel any happier. The valid conclusion from this is merely that power over nature is not the only condition of human happiness, just as it is not the only goal of civilization's efforts, and there is no ground for inferring that its technical progress is worthless from the standpoint of happiness. It prompts one to exclaim: Is it not then a positive pleasure, an unequivocal gain in happiness, to be able to hear, whenever I like, the voice of a child living hundreds of miles away, or to know directly a friend of mine arrives at his destination that he has come well and safely through the long and troublesome voyage? And is it nothing that medical science has succeeded in enormously reducing the mortality of young children, the dangers of infection for women in childbirth, indeed, in very considerably prolonging the average length of human life? And there is still a long list one could add to these benefits that we owe to the much-despised era of scientific and practical progress—but a critical, pessimistic voice makes itself heard, say-

ing that most of these advantages follow the model of those "cheap pleasures" in the anecdote. One gets this enjoyment by sticking one's bare leg outside the bedclothes on a cold winter's night and then drawing it in again. If there were no railway to make light of distances, my child would never have left home, and I should not need the telephone to hear his voice. If there were no vessels crossing the ocean, my friend would never have embarked on his voyage, and I should not need the telegraph to relieve my anxiety about him. What is the use of reducing the mortality of children, when it is precisely this reduction which imposes the greatest moderation on us in begetting them, so that taken all round we do not rear more children than in the days before the reign of hygiene, while at the same time we have created difficult conditions for sexual life in marriage and probably counteracted the beneficial effects of natural selection? And what do we gain by a long life when it is full of hardship and starved of joys and so wretched that we can only welcome death as our deliverer?

It seems to be certain that our present-day civilization does not inspire in us a feeling of well-being, but it is very difficult to form an opinion whether in earlier times people felt any happier and what part their cultural conditions played in the question. We always tend to regard trouble objectively, i.e., to place ourselves with our own wants and our own sensibilities in the same conditions, so as to discover what opportunities for happiness or unhappiness we should find in them. This method of considering the problem, which appears to be objective because it ignores the varieties of subjective sensitivity, is of course the most subjective possible, for by applying it one substitutes one's own mental attitude for the unknown attitude of other men. Happiness, on the contrary, is something essentially subjective. However we may shrink in horror at the thought of certain situations, that of the galley-slaves in antiquity, of the peasants in the Thirty Years' War, of the victims of the Inquisition, of the Jews awaiting a pogrom, it is still impossible for us to feel ourselves into the position of these people, to imagine the differences which would be brought about by constitutional obtuseness of feeling, gradual stupefaction, the cessation of all anticipation, and by all the grosser and more subtle ways in which insensibility to both pleasurable and painful sensations can be induced. Moreover, on occasions when the most extreme forms of

suffering have to be endured, special mental protective devices come into operation. It seems to me unprofitable to follow up this aspect of the problem further.

It is time that we should turn our attention to the nature of this culture, the value of which is so much disputed from the point of view of happiness. Until we have learnt something by examining it for ourselves, we will not look round for formulas which express its essence in a few words. We will be content to repeat<sup>1</sup> that the word *culture* describes the sum of the achievements and institutions which differentiate our lives from those of our animal forebears and serve two purposes, namely, that of protecting humanity against nature and of regulating the relations of human beings among themselves. In order to learn more than this, we must bring together the individual features of culture as they are manifested in human communities. We shall have no hesitation in allowing ourselves to be guided by the common usages of language, or, as one might say, the *feeling* of language, confident that we shall thus take into account inner attitudes which still resist expression in abstract terms.

The beginning is easy. We recognize as belonging to culture all the activities and possessions which men use to make the earth serviceable to them, to protect them against the tyranny of natural forces, and so on. There is less doubt about this aspect of civilization than any other. If we go back far enough, we find that the first acts of civilization were the use of tools, the gaining of power over fire, and the construction of dwellings. Among these the acquisition of power over fire stands out as a quite exceptional achievement, without a prototype;<sup>2</sup> while the other two opened up paths

<sup>1</sup> Cf. *The Future of an Illusion*.

<sup>2</sup> Psycho-analytic material, as yet incomplete and not capable of unequivocal interpretation, nevertheless admits of a surmise—which sounds fantastic enough—about the origin of this human feat. It is as if primitive man had had the impulse, when he came in contact with fire, to gratify an infantile pleasure in respect of it and put it out with a stream of urine. The legends that we possess leave no doubt that flames shooting upwards like tongues were originally felt to have a phallic sense. Putting out fire by urinating—which is also introduced in the later fables of Gulliver in Lilliput and Rabelais's Gargantua—therefore represented a sexual act with a man, an enjoyment of masculine potency in homosexual rivalry. Whoever was the first to deny himself this pleasure and spare the fire was able to take it with him and break it in to his own service. By curbing the fire of his own sexual passion, he was able to tame fire as a force of nature. This great cultural victory was thus a reward for refraining from gratification of an instinct. Further, it is as if man had placed woman by the hearth as the guardian of the fire he had taken captive, because her anatomy makes it impossible for her to yield to such

which have ever since been pursued by man, the stimulus towards which is easily imagined. By means of all his tools, man makes his own organs more perfect—both the motor and the sensory—or else removes the obstacles in the way of their activity. Machinery places gigantic power at his disposal which, like his muscles, he can employ in any direction; ships and aircraft have the effect that neither air nor water can prevent his traversing them. With spectacles he corrects the defects of the lens in his own eyes; with telescopes he looks at far distances; with the microscope he overcomes the limitations in visibility due to the structure of his retina. With the photographic camera he has created an instrument which registers transitory visual impressions, just as the gramophone does with equally transient auditory ones; both are at bottom materializations of his own power of memory. With the help of the telephone he can hear at distances which even fairy-tales would treat as insuperable; writing to begin with was the voice of the absent; dwellings were a substitute for the mother's womb, that first abode, in which he was safe and felt so content, for which he probably years ever after.

It sounds like a fairy-tale, but not only that; this story of what man by his science and practical inventions has achieved on this earth, where he first appeared as a weakly member of the animal kingdom, and on which each individual of his species must ever again appear as a helpless infant—O inch of nature!—is a direct fulfilment of all, or of most, of the dearest wishes in his fairy-tales. All these possessions he has acquired through culture. Long ago he formed an ideal conception of omnipotence and omniscience which he embodied in his gods. Whatever seemed unattainable to his desires—or forbidden to him—he attributed to these gods. One may say, therefore, that these gods were the ideals of his culture. Now he has himself approached very near to realizing this ideal, he has nearly become a god himself. But only, it is true, in the way that ideals are usually realized in the general experience of humanity. Not completely; in some respects not at all, in others only by halves. Man has become a god by means of artificial limbs, so to speak, quite magnificent when equipped with all his accessory organs; but they do not grow on him and they still give him trouble at times.

—  
a temptation. It is remarkable how regularly analytic findings testify to the close connection between the ideas of ambition, fire, and urethral erotism.

However, he is entitled to console himself with the thought that this evolution will not come to an end in A.D. 1930. Future ages will produce further great advances in this realm of culture, probably inconceivable now, and will increase man's likeness to a god still more. But with the aim of our study in mind, we will not forget, all the same, that the human being of today is not happy with all his likeness to a god.

Thus we recognize that a country has attained a high level of civilization when we find that everything in it that can be helpful in exploiting the earth for man's benefit and in protecting him against nature—everything, in short, that is useful to him—is cultivated and effectively protected. In such a country, the course of rivers which threaten to overflow their banks is regulated, their waters guided through canals to places where they are needed. The soil is industriously cultivated and planted with the vegetation suited to it; the mineral wealth is brought up assiduously from the depths and wrought into the implements and utensils that are required. The means of communications are frequent, rapid, and reliable; wild and dangerous animals have been exterminated, the breeding of tamed and domesticated ones prospers. But we demand other things besides these of civilization, and curiously enough, we expect to find them existing in the same countries. As if we wished to repudiate the first requisition we made, we count it also as proof of a high level of civilization when we see that the industry of the inhabitants is applied as well to things which are not in the least useful and, on the contrary seem to be useless, e.g., when the parks and gardens in a town, which are necessary as playgrounds and air-reservoirs, also bear flowering plants, or when the windows of dwellings are adorned with flowers. We soon become aware that the useless thing which we require of civilization is beauty; we expect a cultured people to revere beauty where it is found in nature and to create it in their handiwork so far as they are able. But this is far from exhausting what we require of civilization. Besides, we expect to see the signs of cleanliness and order. We do not think highly of the cultural level of an English country town in the time of Shakespeare when we read that there was a tall dung-heap in front of his father's house in Stratford; we are indignant and call it "barbarous," which is the opposite of civilized, when we find the paths in the Wiener Wald littered with paper. Dirt of any kind seems to us incompatible with

civilization; we extend our demands for cleanliness to the human body also, and are amazed to hear what an objectionable odour emanated from the person of the Roi Soleil; we shake our heads when we are shown the tiny wash-basin on the Isola Bella which Napoleon used for his daily ablutions. Indeed, we are not surprised if anyone employs the use of soap as a direct measure of civilization. It is the same with order, which, like cleanliness, relates entirely to man's handiwork. But whereas we cannot expect cleanliness in nature, order has, on the contrary, been imitated from nature; man's observations of the great astronomical periodicities not only furnished him with a model, but formed the ground-plan of his first attempts to introduce order into his own life. Order is a kind of repetition-compulsion by which it is ordained once for all when, where and how a thing shall be done so that on every similar occasion doubt and hesitation shall be avoided. The benefits of order are incontestable: it enables us to use space and time to the best advantage, while saving expenditure of mental energy. One would be justified in expecting that it would have ingrained itself from the start and without opposition into all human activities; and one may well wonder that this has not happened, and that, on the contrary, human beings manifest an inborn tendency to negligence, irregularity, and untrustworthiness in their work, and have to be laboriously trained to imitate the example of their celestial models.

Beauty, cleanliness, and order clearly occupy a peculiar position among the requirements of civilization. No one will maintain that they are as essential to life as the activities aimed at controlling the forces of nature and as other factors which we have yet to mention; and yet no one would willingly relegate them to the background as trivial matters. Beauty is an instance which plainly shows that culture is not simply utilitarian in its aims, for the lack of beauty is a thing we cannot tolerate in civilization. The utilitarian advantages of order are quite apparent; with regard to cleanliness, we have to remember that it is required of us by hygiene, and we may surmise that even before the days of scientific prophylaxis the connection between the two was not altogether unsuspected by mankind. But these aims and endeavours of culture are not entirely to be explained on utilitarian lines; there must be something else at work besides.

According to general opinion, however, there

is one feature of culture which characterizes it better than any other, and that is the value it sets upon the higher mental activities—intellectual, scientific, and aesthetic achievement—the leading part it concedes to ideas in human life. First and foremost among these ideas come the religious systems with their complicated evolution, on which I have elsewhere endeavoured to throw a light; next to them come philosophical speculations; and last, the ideals man has formed, his conceptions of the perfection possible in an individual, in a people, in humanity as a whole, and the demands he makes on the basis of these conceptions. These creations of his mind are not independent of each other; on the contrary, they are closely interwoven, and this complicates the attempt to describe them, as well as that to trace their psychological derivation. If we assume as a general hypothesis that the force behind all human activities is a striving towards the two convergent aims of profit and pleasure, we must then acknowledge this as valid also for these other manifestations of culture, although it can be plainly recognized as true only in respect of science and art. It cannot be doubted, however, that the remainder, too, correspond to some powerful need in human beings—perhaps to one which develops fully only in a minority of people. Nor may we allow ourselves to be misled by our own judgments concerning the value of any of these religious or philosophical systems or of these ideals; whether we look upon them as the highest achievement of the human mind, or whether we deplore them as fallacies, one must acknowledge that where they exist, and especially where they are in the ascendant, they testify to a high level of civilization.

We now have to consider the last, and certainly by no means the least important, of the components of culture, namely, the ways in which social relations, the relations of one man to another, are regulated, all that has to do with him as a neighbour, a source of help, a sexual object to others, a member of a family or of a state. It is especially difficult in this matter to remain unbiased by any ideal standards and to ascertain exactly what is specifically cultural here. Perhaps one might begin with the statement that the first attempt ever made to regulate these social relations already contained the essential element of civilization. Had no such attempt been made, these relations would be subject to the wills of individuals: that is to say, the man who was physically strongest

would decide things in accordance with his own interests and desires. The situation would remain the same, even though this strong man should in his turn meet with another who was stronger than he. Human life in communities only becomes possible when a number of men unite together in strength superior to any single individual and remain united against all single individuals. The strength of this united body is then opposed as *right* against the strength of any individual, which is condemned as *brute force*. This substitution of the power of a united number for the power of a single man is the decisive step towards civilization. The essence of it lies in the circumstance that the members of the community have restricted their possibilities of gratification, whereas the individual recognized no such restrictions. The first requisite of culture, therefore, is justice—that is, the assurance that a law once made will not be broken in favour of any individual. This implies nothing about the ethical value of any such law. The further course of cultural development seems to tend towards ensuring that the law shall no longer represent the will of any small body—caste, tribe, section of the population—which may behave like a predatory individual towards other such groups perhaps containing larger numbers. The end-result would be a state of law to which all—that is, all who are capable of uniting—have contributed by making some sacrifice of their own desires, and which leaves none—again with the same exception—at the mercy of brute force.

The liberty of the individual is not a benefit of culture. It was greatest before any culture, though indeed it had little value at that time, because the individual was hardly in a position to defend it. Liberty has undergone restrictions through the evolution of civilization, and justice demands that these restrictions shall apply to all. The desire for freedom that makes itself felt in a human community may be a revolt against some existing injustice and so may prove favourable to a further development of civilization and remain compatible with it. But it may also have its origin in the primitive roots of the personality, still unfettered by civilizing influences, and so become a source of antagonism to culture. Thus the cry for freedom is directed either against particular forms or demands of culture or else against culture itself. It does not seem as if man could be brought by any sort of influence to change his nature into that of the ants; he will always, one imagines, defend his claim to individual

freedom against the will of the multitude. A great part of the struggles of mankind centres round the single task of finding some expedient (i.e., satisfying) solution between these individual claims and those of the civilized community; it is one of the problems of man's fate whether this solution can be arrived at in some particular form of culture or whether the conflict will prove irreconcilable.

We have obtained a clear impression of the general picture presented by culture through adopting the common view as to which aspects of human life are to be called cultural; but it is true that so far we have discovered nothing that is not common knowledge. We have, however, at the same time guarded ourselves against accepting the misconception that civilization is synonymous with becoming perfect, is the path by which man is ordained to reach perfection. But now a certain point of view presses for consideration; it will lead perhaps in another direction. The evolution of culture seems to us a peculiar kind of process passing over humanity, of which several aspects strike us as familiar. We can describe this process in terms of the modifications it effects on the known human instinctual dispositions, which it is the economic task of our lives to satisfy. Some of these instincts become absorbed, as it were, so that something appears in place of them which in an individual we call a *character-trait*. The most remarkable example of this process is found in respect of the anal erotism of young human beings. Their primary interest in the excretory function, its organs and products, is changed in the course of their growth into a group of traits that we know well—thriftiness, orderliness, and cleanliness—valuable and welcome qualities in themselves, which, however, may be intensified till they visibly dominate the personality and produce what we call the anal character. How this happens we do not know; but there is no doubt about the accuracy of this conclusion.<sup>1</sup> Now, we have seen that order and cleanliness are essentially cultural demands, although the necessity of them for survival is not particularly apparent, any more than their suitability as sources of pleasure. At this point we must be struck for the first time with the similarity between the process of cultural development and that of the libidinal development in an individual. Other instincts have to be induced to change

the conditions of their gratification, to find it along other paths, a process which is usually identical with what we know so well as sublimation (of the aim of an instinct), but which can sometimes be differentiated from this. Sublimation of instinct is an especially conspicuous feature of cultural evolution; this it is that makes it possible for the higher mental operations, scientific, artistic, ideological activities, to play such an important part in civilized life. If one were to yield to a first impression, one would be tempted to say that sublimation is a fate which has been forced upon instincts by culture alone. But it is better to reflect over this a while longer. Thirdly and lastly, and this seems most important of all, it is impossible to ignore the extent to which civilization is built up on renunciation of instinctual gratifications, the degree to which the existence of civilization presupposes the non-gratification (suppression, repression, or something else?) of powerful instinctual urgencies. This *cultural privation* dominates the whole field of social relations between human beings; we know already that it is the cause of the antagonism against which all civilization has to fight. It sets hard tasks for our scientific work, too; we have a great deal to explain here. It is not easy to understand how it can become possible to withhold satisfaction from an instinct. Nor is it by any means without risk to do so; if the deprivation is not made good economically, one may be certain of producing serious disorders.

But now, if we wish to know what use it is to us to have recognized the evolution of culture as a special process, comparable to the normal growth of an individual to maturity, we must clearly attack another problem and put the question: What are the influences to which the evolution of culture owes its origin, how did it arise, and what determined its course?

#### IV

THIS task seems too big a one; one may well confess oneself diffident. Here follows what little I have been able to elicit about it.

Once primitive man had made the discovery that it lay in his own hands—speaking literally—to improve his lot on earth by working, it cannot have been a matter of indifference to him whether another man worked with him or against him. The other acquired the value of a fellow-worker, and it was advantageous to live with him. Even earlier, in his ape-like prehistory, man had adopted the habit of forming families: his first helpers were probably the

<sup>1</sup> Cf. "Character and Anal Erotism" (1908), *Collected Papers*, II; also numerous contributions to the subject by Ernest Jones and others.

members of his family. One may suppose that the founding of families was in some way connected with the period when the need for genital satisfaction, no longer appearing like an occasional guest who turns up suddenly and then vanishes without letting one hear anything of him for long intervals, had settled down with each man like a permanent lodger. When this happened, the male acquired a motive for keeping the female, or rather, his sexual objects, near him; while the female, who wanted not to be separated from her helpless young, in their interests, too, had to stay by the stronger male.<sup>1</sup> In this primitive family one

<sup>1</sup> The organic periodicity of the sexual process has persisted, it is true, but its effect on mental sexual excitation has been almost reversed. This change is connected primarily with the diminishing importance of the olfactory stimuli by means of which the menstrual process produced sexual excitement in the mind of the male. Their function was taken over by visual stimuli, which could operate permanently, instead of intermittently like the olfactory ones. The *taboo of menstruation* has its origin in this *organic repression*, which acted as a barrier against a phase of development that had been surpassed; all its other motivations are probably of a secondary nature. (Cf. C. D. Daly, "*Hindumythologie und Kastrationskomplex*," *Imago*, Vol. XIII, 1927.) This process is repeated on a different level when the gods of a foregone cultural epoch are changed into demons in the next. The diminution in importance of olfactory stimuli seems itself, however, to be a consequence of man's erecting himself from the earth, of his adoption of an upright gait, which made his genitals, that before had been covered, visible and in need of protection and so evoked feelings of shame. Man's erect posture, therefore, would represent the beginning of the momentous process of cultural evolution. The chain of development would run from this onward, through the diminution in the importance of olfactory stimuli and the isolation of women at their periods, to a time when visual stimuli became paramount, the genitals became visible, further till sexual excitation became constant and the family was founded, and so to the threshold of human culture. This is only a theoretical speculation, but it is important enough to be worth checking carefully by the conditions obtaining among the animals closely allied to man.

There is an unmistakable social factor at work in the impulse of civilization towards cleanliness, which has been subsequently justified by considerations of hygiene but had nevertheless found expression before they were appreciated. The impulse towards cleanliness originates in the striving to get rid of excretions which have become unpleasant to the sense-perceptions. We know that things are different in the nursery. Excreta arouse no aversion in children; they seem precious to them, as being parts of their own bodies which have been detached from them. The training of children is very energetic in this particular; its object is to expedite the development that lies ahead of them, according to which the excreta are to become worthless, disgusting, horrible, and despicable to them. Such a reversal of values would be almost impossible to bring about, were it not that these substances expelled from the body are destined by their strong odours to share the fate that overtook the olfactory stimuli after man had erected himself from the ground. Anal erotism, therefore, is from the first subjected to the *organic repression* which opened up the way to culture. The social factor which has been active in the further modifications of anal erotism comes into play with the fact that in spite of all man's evolutionary progress the smell

essential feature of culture is lacking; the will of the father, the head of it, was unfettered. I have endeavoured in *Totem and Taboo* to show how the way led from this family-life to the succeeding phase of communal existence in the form of a band of brothers. By overpowering the father, the sons had discovered that several men united can be stronger than a single man. The totemic stage of culture is founded upon the restrictions that the band were obliged to impose on one another in order to maintain the new system. These taboos were the first *right* or law. The life of human beings in common therefore had a twofold foundation, i.e., the compulsion to work, created by external necessity, and the power of love, causing the male to wish to keep his sexual object, the female, near him, and the female to keep near her that part of herself which has become detached from her, her child. Eros and Ananke were the parents of human culture, too. The first result of culture was that a larger number of human beings could then live together in common. And since the two great powers were here co-operating together, one might have expected that further cultural evolution would have proceeded smoothly towards even greater mastery over the external world, as well as towards greater extension in the numbers of men sharing the life in common. Nor is it easy to understand how this culture can be felt as anything but satisfying by those who partake of it.

Before we go on to enquire where the disturbances in it arise, we will let ourselves digress from the point that love was one of the founders of culture and so fill a gap left in our previous discussion. We said that man, having found by experience that sexual (genital) love afforded him his greatest gratification, so that it became in effect a prototype of all happiness to him, must have been thereby impelled to seek his happiness further along the path of sexual relations, to make genital erotism the central point of his life. We went on to say that in so doing he becomes to a very dangerous degree dependent on a part of the outer world,

of his own excretions is scarcely disagreeable to him yet, but so far only that of the evacuations of others. The man who is not clean, i.e., who does not eliminate his excretions, therefore offends others, shows no consideration for them—a fact which is exemplified in the commonest and most forcible terms of abuse. It would be incomprehensible, too, that man should use as an abusive epithet the name of his most faithful friend in the animal world, if dogs did not incur the contempt of men through two of their characteristics, i.e., that they are creatures of smell and have no horror of excrement, and, secondly, that they are not ashamed of their sexual functions.

namely, on his chosen love-object, and this exposes him to most painful sufferings if he is rejected by it or loses it through death or defection. The wise men of all ages have consequently warned us emphatically against this way of life; but in spite of all it retains its attraction for a great number of people.

A small minority are enabled by their constitution, nevertheless, to find happiness along the path of love; but far-reaching mental transformations of the erotic function are necessary before this is possible. These people make themselves independent of their object's acquiescence by transferring the main value from the fact of being loved to their own act of loving; they protect themselves against loss of it by attaching their love not to individual objects but to all men equally, and they avoid the uncertainties and disappointments of genital love by turning away from its sexual aim and modifying the instinct into an impulse with an *inhibited aim*. The state which they induce in themselves by this process—an unchangeable, undeviating, tender attitude—has little superficial likeness to the stormy vicissitudes of genital love, from which it is nevertheless derived. It seems that Saint Francis of Assisi may have carried this method of using love to produce an inner feeling of happiness as far as anyone; what we are thus characterizing as one of the procedures by which the pleasure-principle fulfils itself has in fact been linked up in many ways with religion; the connection between them may lie in those remote fastnesses of the mind where the distinctions between the ego and objects, and between the various objects, become matters of indifference. From one ethical standpoint, the deeper motivation of which will later become clear to us, this inclination towards an all-embracing love of others and of the world at large is regarded as the highest state of mind of which man is capable. Even at this early stage in the discussion, I will not withhold the two principal objections we have to raise against this view. A love that does not discriminate seems to us to lose some of its own value, since it does an injustice to its object. And secondly, not all men are worthy of love.

The love that instituted the family still retains its power; in its original form it does not stop short of direct sexual satisfaction, and in its modified form, as aim-inhibited friendliness, it influences our civilization. In both these forms it carries on its task of binding men and women to one another, and it does this with

greater intensity than can be achieved through the interest of work in common. The casual and undifferentiated way in which the word *love* is employed by language has its genetic justification. In general usage, the relation between a man and a woman whose genital desires have led them to found a family is called *love*; but the positive attitude of feeling between parents and children, between brothers and sisters in a family, is also called *love*, although to us this relation merits the description of *aim-inhibited love* or *affection*. Love with an inhibited aim was indeed originally full sensual love and in men's unconscious minds is so still. Both of them, the sensual and the aim-inhibited forms, reach out beyond the family and create new bonds with others who before were strangers. Genital love leads to the forming of new families; aim-inhibited love to *friendships*, which are valuable culturally because they do not entail many of the limitations of genital love—for instance, its exclusiveness. But the interrelations between love and culture lose their simplicity as development proceeds. On the one hand, love opposes the interests of culture; on the other, culture menaces love with grievous restrictions.

This rift between them seems inevitable; the cause of it is not immediately recognizable. It expresses itself first in a conflict between the family and the larger community to which the individual belongs. We have seen already that one of culture's principal endeavours is to cement men and women together into larger units. But the family will not give up the individual. The closer the attachment between the members of it, the more they often tend to remain aloof from others, and the harder it is for them to enter into the wider circle of the world at large. That form of life in common which is phylogenetically older, and is in childhood its only form, resists being displaced by the type that becomes acquired later with culture. Detachment from the family has become a task that awaits every adolescent, and often society helps him through it with pubertal and initiatory rites. One gets the impression that these difficulties form an integral part of every process of mental evolution—and indeed, at bottom, of every organic development, too.

The next discord is caused by women, who soon become antithetical to cultural trends and spread around them their conservative influence—the women who at the beginning laid the foundations of culture by the appeal of their love. Women represent the interests of the

family and sexual life; the work of civilization has become more and more men's business; it confronts them with ever harder tasks, compels them to sublimations of instinct which women are not easily able to achieve. Since man has not an unlimited amount of mental energy at his disposal, he must accomplish his tasks by distributing his libido to the best advantage. What he employs for cultural purposes he withdraws to a great extent from women and his sexual life; his constant association with men and his dependence on his relations with them even estrange him from his duties as husband and father. Woman finds herself thus forced into the background by the claims of culture, and she adopts an inimical attitude towards it.

The tendency of culture to set restrictions upon sexual life is no less evident than its other aim of widening its sphere of operations. Even the earliest phase of it, the totemic, brought in its train the prohibition against incestuous object-choice, perhaps the most maiming wound ever inflicted throughout the ages on the erotic life of man. Further limitations are laid on it by taboos, laws, and customs, which touch men as well as women. Various types of culture differ in the lengths to which they carry this; and the material structure of the social fabric also affects the measure of sexual freedom that remains. We have seen that culture obeys the laws of psychological economic necessity in making the restrictions, for it obtains a great part of the mental energy it needs by subtracting it from sexuality. Culture behaves towards sexuality in this respect like a tribe or a section of the population which has gained the upper hand and is exploiting the rest to its own advantage. Fear of a revolt among the oppressed then becomes a motive for even stricter regulations. A high-water mark in this type of development has been reached in our Western European civilization. Psychologically it is fully justified in beginning by censuring any manifestations of the sexual life of children, for there would be no prospect of curbing the sexual desires of adults if the ground had not been prepared for it in childhood. Nevertheless, there is no sort of justification for the lengths beyond this to which civilized society goes in actually denying the existence of these manifestations, which are not merely demonstrable but positively glaring. Where sexually mature persons are concerned, object-choice is further narrowed down to the opposite sex and most of the extra-genital forms of satisfaction are in-

terdicted as perversions. The standard which declares itself in these prohibitions is that of a sexual life identical for all; it pays no heed to the disparities in the inborn and acquired sexual constitutions of individuals and cuts off a considerable number of them from sexual enjoyment, thus becoming a cause of grievous injustice. The effect of these restrictive measures might presumably be that all the sexual interest of those who are normal and not constitutionally handicapped could flow without further forfeiture into the channel left open to it. But the only outlet not thus censured, heterosexual genital love, is further circumscribed by the barriers of legitimacy and monogamy. Present-day civilization gives us plainly to understand that sexual relations are permitted only on the basis of a final, indissoluble bond between a man and woman; that sexuality as a source of enjoyment for its own sake is unacceptable to it; and that its intention is to tolerate it only as the hitherto irreplaceable means of multiplying the human race.

This, of course, represents an extreme. Everyone knows that it has proved impossible to put it into execution, even for short periods. Only the weaklings have submitted to such comprehensive interference with their sexual freedom, and stronger natures have done so only under one compensatory condition, of which mention may be made later. Civilized society has seen itself obliged to pass over in silence many transgressions which by its own ordinances it ought to have penalized. This does not justify anyone, however, in leaning towards the other side and assuming that, because it does not achieve all it aims at, such an attitude on the part of society is altogether harmless. The sexual life of civilized man is seriously disabled, whatever we may say; it sometimes makes an impression of being a function in process of becoming atrophied, just as organs like our teeth and our hair seem to be. One is probably right in supposing that the importance of sexuality as a source of pleasurable sensations, i.e., as a means of fulfilling the purpose of life, has perceptibly decreased.<sup>1</sup> Sometimes one imagines one perceives that it is not only the oppression of culture, but something in the nature of the function itself that denies us full satisfaction and urges us in other direc-

<sup>1</sup> There is a short story, which I valued long ago, by a highly sensitive writer, the Englishman, John Galsworthy, who today enjoys general recognition; it is called "The Apple Tree." It shows in a very moving and forcible way how there is no longer any place in present-day civilized life for a simple natural love between two human beings.

tions. This may be an error; it is hard to decide.<sup>1</sup>

<sup>1</sup> The following considerations would support the view expressed above. Man, too, is an animal with an unmistakably bisexual disposition. The individual represents a fusion of two symmetrical halves, of which, according to many authorities, one is purely male, the other female. It is equally possible that each half was originally hermaphroditic. Sex is a biological fact which is hard to evaluate psychologically, although it is of extraordinary importance in mental life. We are accustomed to say that every human being displays both male and female instinctual impulses, needs, and attributes, but the characteristics of what is male and female can only be demonstrated in anatomy, and not in psychology. Where the latter is concerned, the antithesis of sex fades away into that of activity and passivity, and we far too readily identify activity with masculinity and passivity with femininity, a statement which is by no means universally confirmed in the animal world. The theory of bisexuality is still very obscure, and in psycho-analysis we must be painfully aware of the disadvantage we are under as long as it still remains unconnected with the theory of instincts. However this may be, if we assume it to be a fact that each individual has both male and female desires which need satisfaction in his sexual life, we shall be prepared for the possibility that these needs will not both be gratified on the same object, and that they will interfere with each other, if they cannot be kept apart so that each impulse flows into a special channel suited for it. Another difficulty arises from the circumstance that so often a measure of direct aggressiveness is coupled with an erotic relationship, over and above its inherent sadistic components. The love-object does not always view these complications with the degree of understanding and tolerance manifested by the peasant woman who complained that her husband did not love her any more, because he had not beaten her for a week.

The conjecture which leads furthest, however, is that—and here we come back to the remarks in the footnote on p. 782—the whole of sexuality, and not merely anal erotism, is threatened with falling a victim to the organic repression consequent upon man's adoption of the erect posture and the lowering in value of the sense of smell; so that since that time the sexual function has been associated with a resistance not susceptible of further explanation, which puts obstacles in the way of full satisfaction and forces it away from its sexual aim towards sublimations and displacements of libido. I am aware that Bleuler (in "*Der Sexualwiderstand*," *Jahrbuch für psychoanalytische und psychopathologische Forschungen*, Vol. V, 1913) once pointed out the existence of a fundamental tendency of this kind towards rejecting sexual life. All neurotics, and many others too, take exception to the fact that *inter urinas et faeces nascitur* [We are born among urine and faeces]. The genitals, too, excite the olfactory sense strongly in a way that many people cannot tolerate and which spoils sexual intercourse for them. Thus we should find, as the deepest root of the sexual repression that marches with culture, the organic defence of the new form of life that began with the erect posture against the earliest type of animal existence—a result of scientific researches that coincides in a curious way with often expressed vulgar prejudices. At the present time, nevertheless, these results are but unconfirmed possibilities, not yet scientifically substantiated. Nor should we forget that, in spite of the undeniable diminution in the importance of olfactory stimuli, there exist even in Europe races who prize highly as aphrodisiacs the strong genital odours so objectionable to us and who will not renounce them. (Cf. the reports of folkloristic information obtained by Iwan Bloch's "Questionnaire," appearing under the title of "*Über den Geruchssinn in der vita sexualis*" in various volumes of Friedrich S. Krauss' *Anthropophyteia*.)

## V

PSYCHO-ANALYTIC work has shown that these frustrations in respect of sexual life are especially unendurable to the so-called neurotics among us. These persons manufacture substitute-gratifications for themselves in their symptoms, which, however, are either painful in themselves or become the cause of suffering owing to the difficulties they create with the person's environment and society at large. It is easy to understand the latter fact, but the former presents us with a new problem. But culture demands other sacrifices besides that of sexual gratifications.

We have regarded the difficulties in the development of civilization as part of the general difficulty accompanying all evolution, for we have traced them to the inertia of libido, its disinclination to relinquish an old position in favour of a new one. It is much the same thing if we say that the conflict between civilization and sexuality is caused by the circumstance that sexual love is a relationship between two people, in which a third can only be superfluous or disturbing, whereas civilization is founded on relations between larger groups of persons. When a love-relationship is at its height, no room is left for any interest in the surrounding world; the pair of lovers are sufficient unto themselves, do not even need the child they have in common to make them happy. In no other case does Eros so plainly betray the core of his being, his aim of making one out of many; but when he has achieved it in the proverbial way through the love of two human beings, he is not willing to go further.

From all this we might well imagine that a civilized community could consist of pairs of individuals such as this, libidinally satisfied in each other, and linked to all the others by work and common interests. If this were so, culture would not need to levy energy from sexuality. But such a desirable state of things does not exist and never has existed; in actuality, culture is not content with such limited ties as these; we see that it endeavours to bind the members of the community to one another by libidinal ties as well, that it makes use of every means and favours every avenue by which powerful identifications can be created among them, and that it exacts a heavy toll of aim-inhibited libido in order to strengthen communities by bonds of friendship between the members. Restrictions upon sexual life are unavoidable if this object is to be attained. But we cannot see the necessity that forces culture

along this path and gives rise to its antagonism to sexuality. It must be due to some disturbing influence not yet detected by us.

We may find the clue in one of the so-called *ideal standards* of civilized society. It runs: "Thou shalt love thy neighbour as thyself." It is world-renowned, undoubtedly older than Christianity which parades it as its proudest profession, yet certainly not very old; in historical times, men still knew nothing of it. We will adopt a naïve attitude towards it, as if we were meeting it for the first time. Thereupon, we find ourselves unable to suppress a feeling of astonishment, as at something unnatural. Why should we do this? What good is it to us? Above all, how can we do such a thing? How could it possibly be done? My love seems to me a valuable thing that I have no right to throw away without reflection. It imposes obligations on me which I must be prepared to make sacrifices to fulfil. If I love someone, he must be worthy of it in some way or other. (I am leaving out of account now the use he may be to me, as well as his possible significance to me as a sexual object; neither of these two kinds of relationship between us come into question where the injunction to love my neighbour is concerned.) He will be worthy of it if he is so like me in important respects that I can love myself in him; worthy of it if he is so much more perfect than I that I can love my ideal of myself in him; I must love him if he is the son of my friend, since the pain my friend would feel if anything untoward happened to him would be my pain—I should have to share it. But if he is a stranger to me and cannot attract me by any value he has in himself or any significance he may have already acquired in my emotional life, it will be hard for me to love him. I shall even be doing wrong if I do, for my love is valued as a privilege by all those belonging to me; it is an injustice to them if I put a stranger on a level with them. But if I am to love him (with that kind of universal love) simply because he, too, is a denizen of the earth, like an insect or an earthworm or a grass-snake, then I fear that but a small modicum of love will fall to his lot and it would be impossible for me to give him as much as by all the laws of reason I am entitled to retain for myself. What is the point of an injunction promulgated with such solemnity, if reason does not recommend it to us?

When I look more closely, I find still further difficulties. Not merely is this stranger on the whole not worthy of love, but, to be honest, I

must confess he has more claim to my hostility, even to my hatred. He does not seem to have the least trace of love for me, does not show me the slightest consideration. If it will do him any good, he has no hesitation in injuring me, never even asking himself whether the amount of advantage he gains by it bears any proportion to the amount of wrong done to me. What is more, he does not even need to get an advantage from it; if he can merely get a little pleasure out of it, he thinks nothing of jeering at me, insulting me, slandering me, showing his power over me; and the more secure he feels himself, or the more helpless I am, with so much more certainty can I expect this behaviour from him towards me. If he behaved differently, if he showed me consideration and did not molest me, I should in any case, without the aforesaid commandment, be willing to treat him similarly. If the high-sounding ordinance had run: "Love thy neighbour as thy neighbour loves thee," I should not take objection to it. And there is a second commandment that seems to me even more incomprehensible, and arouses still stronger opposition in me. It is: "Love thine enemies." When I think it over, however, I am wrong in treating it as a greater imposition. It is at bottom the same thing.<sup>1</sup>

I imagine now I hear a voice gravely adjuring me: "Just because thy neighbour is not worthy of thy love, is probably full of enmity towards thee, thou shouldst love him as thyself." I then perceive the case to be like that of *Credo, quia absurdum*.<sup>2</sup>

Now it is, of course, very probable that my neighbour, when he is commanded to love me as himself, will answer exactly as I have done and reject me for the same reasons. I hope he will not have the same objective grounds for doing so, but he will hope so as well. Even so, there are variations in men's behaviour which ethics, disregarding the fact that they are determined, classifies as *good* and *evil*. As long as

<sup>1</sup> A great poet may permit himself, at least in jest, to give utterance to psychological truths that are heavily censured. Thus Heine: "Mine is the most peaceable disposition. My wishes are a humble dwelling with a thatched roof, but a good bed, good food, milk and butter of the freshest, flowers at my windows, some fine tall trees before my door; and if the good God wants to make me completely happy, he will grant me the joy of seeing some six or seven of my enemies hanging from these trees. With my heart full of deep emotion I shall forgive them before they die all the wrong they did me in their lifetime—true, one must forgive one's enemies, but not until they are brought to execution."—Heine, *Gedanken und Einfälle*.

<sup>2</sup> I believe it, because it is absurd.—Ed.

these undeniable variations have not been abolished, conformity to the highest ethical standards constitutes a betrayal of the interests of culture, for it puts a direct premium on wickedness. One is irresistibly reminded here of an incident in the French Chamber when capital punishment was being discussed; the speech of a member who had passionately supported its abolition was being applauded with loud acclamation, when suddenly a voice was heard calling out from the back of the room, "*Que messieurs les assassins commencent!*"<sup>1</sup>

The bit of truth behind all this—one so eagerly denied—is that men are not gentle, friendly creatures wishing for love, who simply defend themselves if they are attacked, but that a powerful measure of desire for aggression has to be reckoned as part of their instinctual endowment. The result is that their neighbour is to them not only a possible helper or sexual object, but also a temptation to them to gratify their aggressiveness on him, to exploit his capacity for work without recompense, to use him sexually without his consent, to seize his possessions, to humiliate him, to cause him pain, to torture and kill him. *Homo homini lupus*;<sup>2</sup> who has the courage to dispute it in the face of all the evidence in his own life and in history? This aggressive cruelty usually lies in wait for some provocation, or else it steps into the service of some other purpose, the aim of which might as well have been achieved by milder measures. In circumstances that favour it, when those forces in the mind which ordinarily inhibit it cease to operate, it also manifests itself spontaneously and reveals men as savage beasts to whom the thought of sparing their own kind is alien. Anyone who calls to mind the atrocities of the early migrations, of the invasion by the Huns, or by the so-called Mongols under Jenghiz Khan and Tamurlane, of the sack of Jerusalem by the pious Crusaders, even indeed the horrors of the last World War, will have to bow his head humbly before the truth of this view of man.

The existence of this tendency to aggression which we can detect in ourselves and rightly presume to be present in others is the factor that disturbs our relations with our neighbours and makes it necessary for culture to institute its high demands. Civilized society is perpetually menaced with disintegration through this primary hostility of men towards one another.

Their interests in their common work would not hold them together; the passions of instinct are stronger than reasoned interests. Culture has to call up every possible reinforcement in order to erect barriers against the aggressive instincts of men and hold their manifestations in check by reaction-formations in men's minds. Hence its system of methods by which mankind is to be driven to identifications and aim-inhibited love-relationships; hence the restrictions on sexual life; and hence, too, its ideal command to love one's neighbour as oneself, which is really justified by the fact that nothing is so completely at variance with original human nature as this. With all its striving, this endeavour of culture's has so far not achieved very much. Civilization expects to prevent the worst atrocities of brutal violence by taking upon itself the right to employ violence against criminals, but the law is not able to lay hands on the more discreet and subtle forms in which human aggressions are expressed. The time comes when every one of us has to abandon the illusory anticipations with which in our youth we regarded our fellow-men, and when we realize how much hardship and suffering we have been caused in life through their ill-will. It would be unfair, however, to reproach culture with trying to eliminate all disputes and competition from human concerns. These things are undoubtedly indispensable; but opposition is not necessarily enmity, only it may be misused to make an opening for it.

The Communists believe they have found a way of delivering us from this evil. Man is whole-heartedly good and friendly to his neighbour, they say, but the system of private property has corrupted his nature. The possession of private property gives power to the individual and thence the temptation arises to ill-treat his neighbour; the man who is excluded from the possession of property is obliged to rebel in hostility against the oppressor. If private property were abolished, all valuables held in common and all allowed to share in the enjoyment of them, ill-will and enmity would disappear from among men. Since all needs would be satisfied, none would have any reason to regard another as an enemy; all would willingly undertake the work which is necessary. I have no concern with any economic criticisms of the communistic system; I cannot enquire into whether the abolition of private property is advantageous and expedient.<sup>3</sup> But I am able

<sup>1</sup> Let the murderers begin!—Ed.

<sup>2</sup> Man is to man a wolf.—Ed.

<sup>3</sup> Anyone who has been through the misery of poverty in his youth, and has endured the indifference and

to recognize that psychologically it is founded on an untenable illusion. By abolishing private property one deprives the human love of aggression of one of its instruments, a strong one undoubtedly, but assuredly not the strongest. It in no way alters the individual differences in power and influence which are turned by aggressiveness to its own use, nor does it change the nature of the instinct in any way. This instinct did not arise as the result of property; it reigned almost supreme in primitive times when possessions were still extremely scanty; it shows itself already in the nursery when possessions have hardly grown out of their original anal shape; it is at the bottom of all the relations of affection and love between human beings—possibly with the single exception of that of a mother to her male child. Suppose that personal rights to material goods are done away with, there still remain prerogatives in sexual relationships, which must arouse the strongest rancour and most violent enmity among men and women who are otherwise equal. Let us suppose this were also to be removed by instituting complete liberty in sexual life, so that the family, the germ-cell of culture, ceased to exist; one could not, it is true, foresee the new paths on which cultural development might then proceed, but one thing one would be bound to expect and that is that the ineffaceable feature of human nature would follow wherever it led.

Men clearly do not find it easy to do without satisfaction of this tendency to aggression that is in them; when deprived of satisfaction of it they are ill at ease. There is an advantage, not to be undervalued, in the existence of smaller communities, through which the aggressive instinct can find an outlet in enmity towards those outside the group. It is always possible to unite considerable numbers of men in love towards one another, so long as there are still some remaining as objects for aggressive manifestations. I once interested myself in the peculiar fact that peoples whose territories are adjacent, and are otherwise closely related, are always at feud with and ridiculing each other,

---

arrogance of those who have possessions, should be exempt from the suspicion that he has no understanding of or goodwill towards the endeavours made to fight the economic inequality of men and all that it leads to. To be sure, if an attempt is made to base this fight upon an abstract demand for equality for all in the name of justice, there is a very obvious objection to be made, namely, that nature began the injustice by the highly unequal way in which she endows individuals physically and mentally, for which there is no help.

as, for instance, the Spaniards and the Portuguese, the North and South Germans, the English and the Scotch, and so on. I gave it the name of *narcissism in respect of minor differences*, which does not do much to explain it. One can now see that it is a convenient and relatively harmless form of satisfaction for aggressive tendencies, through which cohesion amongst the members of a group is made easier. The Jewish people, scattered in all directions as they are, have in this way rendered services which deserve recognition to the development of culture in the countries where they settled; but unfortunately not all the massacres of Jews in the Middle Ages sufficed to procure peace and security for their Christian contemporaries. Once the apostle Paul had laid down universal love between all men as the foundation of his Christian community, the inevitable consequence in Christianity was the utmost intolerance towards all who remained outside of it; the Romans, who had not founded their state on love, were not given to lack of religious toleration, although religion was a concern of the state and the state was permeated through and through with it. Neither was it an unaccountable chance that the dream of a German world-dominion evoked a complementary movement towards anti-semitism; and it is quite intelligible that the attempt to establish a new communistic type of culture in Russia should find psychological support in the persecution of the bourgeois. One only wonders, with some concern, however, how the Soviets will manage when they have exterminated their bourgeois entirely.

If civilization requires such sacrifices, not only of sexuality but also of the aggressive tendencies in mankind, we can better understand why it should be so hard for men to feel happy in it. In actual fact, primitive man was better off in this respect, for he knew nothing of any restrictions on his instincts. As a set-off against this, his prospects of enjoying his happiness for any length of time were very slight. Civilized man has exchanged some part of his chances of happiness for a measure of security. We will not forget, however, that in the primal family only the head of it enjoyed this instinctual freedom; the other members lived in slavish thralldom. The antithesis between a minority enjoying cultural advantages and a majority who are robbed of them was therefore most extreme in that primeval period of culture. With regard to the primitive human types living at the present time, careful in-

vestigation has revealed that their instinctual life is by no means to be envied on account of its freedom; it is subject to restrictions of a different kind but perhaps even more rigorous than is that of modern civilized man.

In rightly finding fault, as we thus do, with our present state of civilization for so inadequately providing us with what we require to make us happy in life, and for the amount of suffering of a probably avoidable nature it lays us open to—in doing our utmost to lay bare the roots of its deficiencies by our unsparing criticisms, we are undoubtedly exercising our just rights and not showing ourselves enemies of culture. We may expect that in the course of time changes will be carried out in our civilization so that it becomes more satisfying to our needs and no longer open to the reproaches we have made against it. But perhaps we shall also accustom ourselves to the idea that there are certain difficulties inherent in the very nature of culture which will not yield to any efforts at reform. Over and above the obligations of putting restrictions upon our instincts, which we see to be inevitable, we are imminently threatened with the dangers of a state one may call *la misère psychologique* of groups. This danger is most menacing where the social forces of cohesion consist predominantly of identifications of the individuals in the group with one another, whilst leading personalities fail to acquire the significance that should fall to them in the process of group-formation.<sup>1</sup> The state of civilization in America at the present day offers a good opportunity for studying this injurious effect of civilization which we have reason to dread. But I will resist the temptation to enter upon a criticism of American culture; I have no desire to give the impression that I would employ American methods myself.

## VI

NEVER before in any of my previous writings have I had the feeling so strongly as I have now that what I am describing is common knowledge, that I am requisitioning paper and ink, and in due course the labour of compositors and printers, in order to expound things that in themselves are obvious. For this reason, if it should appear that the recognition of a special independent instinct of aggression would entail a modification of the psycho-analytical theory of instincts, I should be glad enough to seize upon the idea.

<sup>1</sup> Cf. *Group Psychology*, etc., p. 664 above.

We shall see that this is not so, that it is merely a matter of coming to closer quarters with a conclusion to which we long ago committed ourselves and following it out to its logical consequences. The whole of analytic theory has evolved gradually enough, but the theory of instincts has groped its way forward under greater difficulties than any other part of it. And yet a theory of instincts was so indispensable for the rest that something had to be adopted in place of it. In my utter perplexity at the beginning, I took as my starting-point the poet-philosopher Schiller's aphorism that hunger and love make the world go round. Hunger would serve to represent those instincts which aim at preservation of the individual; love seeks for objects: its chief function, which is favoured in every way by nature, is preservation of the species. Thus first arose the contrast between ego instincts and object instincts. For the energy of the latter instincts, and exclusively for them, I introduced the term *libido*; an antithesis was thus formed between the ego instincts and the libidinal instincts directed towards objects, i.e., love in its widest sense. One of these object instincts, the sadistic, certainly stood out from the rest in that its aim was so very unloving; moreover, it clearly allied itself in many of its aspects with the ego instincts, and its close kinship with instincts of mastery without any libidinal purpose could not be concealed, but these ambiguities could be overcome; in spite of them, sadism plainly belonged to sexual life—the game of cruelty could take the place of the game of love. Neurosis appeared as the outcome of a struggle between the interests of self-preservation and the claims of libido, a struggle in which the ego was victorious, but at the price of great suffering and renunciations.

Every analyst will admit that none of this even now reads like a statement long since recognized as erroneous. All the same, modifications had to be made as our researches advanced from the repressed to the repressing, from the object instincts to the ego. A cardinal point in this advance was the introduction of the concept of narcissism, i.e., the idea that libido cathects the ego itself, that its first dwelling-place was in the ego, and that the latter remains to some extent its permanent headquarters. This narcissistic libido turns in the direction of objects, thus becoming object-libido, and can transform itself back into narcissistic libido. The concept of narcissism made it possible to consider the traumatic

neuroses, as well as many diseases bordering on the psychoses, and also the latter themselves, from the psycho-analytic angle. It was not necessary to abandon the view that the transference-neuroses are attempts on the part of the ego to guard itself against sexuality, but the concept of the libido was jeopardized. Since the ego-instincts were found to be libidinal as well, it seemed for a time inevitable that libido should become synonymous with instinctual energy in general, as C. G. Jung had previously advocated. Yet there still remained in me a kind of conviction, for which as yet there were no grounds, that the instincts could not all be of the same nature. I made the next step in *Beyond the Pleasure Principle* (1920), when the repetition-compulsion and the conservative character of instinctual life first struck me. On the basis of speculations concerning the origin of life and of biological parallels, I drew the conclusion that, beside the instinct preserving the organic substance and binding it into ever larger units,<sup>1</sup> there must exist another in antithesis to this, which would seek to dissolve these units and reinstate their antecedent inorganic state. That is to say, a death instinct as well as Eros; the phenomena of life would then be explicable from the interplay of the two and their counteracting effects on each other. It was not easy, however, to demonstrate the working of this hypothetical death instinct. The manifestations of Eros were conspicuous and audible enough; one might assume that the death instinct worked silently within the organism towards its disintegration, but that, of course, was no proof. The idea that part of the instinct became directed towards the outer world and then showed itself as an instinct of aggression and destruction carried us a step further. The instinct would thus itself have been pressed into the service of Eros, in that the organism would be destroying something animate or inanimate outside itself instead of itself. Conversely, any cessation of this flow outwards must have the effect of intensifying the self-destruction which in any case would always be going on within. From this example one could then surmise that the two kinds of instincts seldom—perhaps never—appear in isolation, but always mingle with each other in different, very varying proportions, and so make themselves unrecognizable to us. Sadism,

long since known to us as a component-instinct of sexuality, would represent a particularly strong admixture of the instinct of destruction into the love impulse; while its counterpart, masochism, would be an alliance between sexuality and the destruction at work within the self, in consequence of which the otherwise imperceptible destructive trend became directly evident and palpable.

The assumption of the existence of a death instinct or a destruction instinct has roused opposition even in analytical circles; I know that there is a great tendency to ascribe all that is dangerous and hostile in love rather to a fundamental bipolarity in its own nature. The conceptions I have summarized here I first put forward only tentatively, but in the course of time they have won such a hold over me that I can no longer think in any other way. To my mind they are theoretically far more fruitful than any others it is possible to employ; they provide us with that simplification, without either ignoring or doing violence to the facts, which is what we strive after in scientific work. I know that we have always had before our eyes manifestations of the destruction instinct fused with erotism, directed outwards and inwards in sadism and masochism; but I can no longer understand how we could have overlooked the universality of non-erotic aggression and destruction, and could have omitted to give it its due significance in our interpretation of life. (It is true that the destructive trend that is directed inwards, when it is not erotically tinged, usually eludes our perceptions.) I can remember my own defensive attitude when the idea of an instinct of destruction first made its appearance in psycho-analytical literature and how long it took until I became accessible to it. That others should have shown the same resistance, and still show it, surprises me less. Those who love fairy-tales do not like it when people speak of the innate tendencies in mankind towards aggression, destruction, and, in addition, cruelty. For God has made them in his own image, with his own perfections; no one wants to be reminded how hard it is to reconcile the undeniable existence—in spite of all the protestations of Christian Science—of evil with His omnipotence and supreme goodness. The devil is, in fact, the best way out in acquittal of God; he can be used to play the same economic rôle of outlet as Jews in the world of Aryan ideals. But even so, one can just as well hold God responsible for the existence of the devil as for the evil he personifies. In view of

<sup>1</sup> The contradiction between the tireless tendency of Eros to spread ever further and the general conservative nature of the instincts here becomes very noticeable; it would serve as the starting-point of enquiries into further problems.

these difficulties, it is expedient for every man to make humble obeisance on suitable occasions in honour of the high-minded nature of men; it will assist him to become universally beloved and much shall be forgiven unto him on account of it.<sup>1</sup>

The name *libido* can again be used to denote the manifestations of the power of Eros in contradistinction to the energy of the death instinct.<sup>2</sup> We must confess that it is more difficult for us to detect the latter, and to a great extent we can merely conjecture its existence as a background to Eros, also that it eludes us wherever it is not betrayed by a fusion with Eros. In sadism, where it bends the erotic aim to its own will and yet at the same time gratifies the sexual craving completely, we can obtain the clearest insight into its nature and its relation to Eros. But even where it shows itself without any sexual purpose, even in the blindest frenzy of destructiveness, one cannot ignore the fact that satisfaction of it is accompanied by an extraordinarily intense narcissistic enjoyment, due to the fulfilment it brings to the ego of its oldest omnipotence-wishes. The instinct of destruction, when tempered and harnessed (as it were, inhibited in its aim) and directed towards objects, is compelled to provide the ego with satisfaction of its needs and with power over nature. Since the assumption of its existence is based essentially on theoretical grounds, it must be confessed that it is not entirely proof against theoretical objections. But this is how things appear to us now in the present state of our knowledge; future research and reflection will undoubtedly bring further light which will decide the question.

In all that follows, I take up the standpoint

<sup>1</sup> In Goethe's Mephistopheles we have a quite exceptionally striking identification of the principle of evil with the instinct of destruction:

*All entities that be  
Deserve their end—nonentity.*

*So all that you name sin, destruction—  
Wickedness, briefly—proves to be  
The native element for me.*

As his adversary, the devil himself cites not what is holy and good, but the power in nature working towards the creation and renewal of life—that is, Eros.

*From air, from water, germs in thousands,  
As from the soil, break forth, break free,  
Dry, wet, warm, cold—a pullulation!  
Had I not laid on flame a reservation,  
Nothing were set apart for me.*

<sup>2</sup> Our present point of view can be roughly expressed in the statement that libido participates in every instinctual manifestation, but that not everything in that manifestation is libido.

that the tendency to aggression is an innate, independent, instinctual disposition in man, and I come back now to the statement that it constitutes the most powerful obstacle to culture. At one point in the course of this discussion, the idea took possession of us that culture was a peculiar process passing over human life and we are still under the influence of this idea. We may add to this that the process proves to be in the service of Eros, which aims at binding together single human individuals, then families, then tribes, races, nations, into one great unity, that of humanity. Why this has to be done we do not know; it is simply the work of Eros. These masses of men must be bound to one another libidinally; necessity alone, the advantages of common work, would not hold them together. The natural instinct of aggressiveness in man, the hostility of each one against all and of all against each one, opposes this program of civilization. This instinct of aggression is the derivative and main representative of the death instinct we have found alongside of Eros, sharing his rule over the earth. And now, it seems to me, the meaning of the evolution of culture is no longer a riddle to us. It must present to us the struggle between Eros and death, between the instincts of life and the instincts of destruction, as it works itself out in the human species. This struggle is what all life essentially consists of and so the evolution of civilization may be simply described as the struggle of the human species for existence.<sup>3</sup> And it is this battle of the Titans that our nurses and governesses try to compose with their lullaby-song of Heaven!

## VII

WHY do the animals, kin to ourselves, not manifest any such cultural struggle? Oh, we don't know. Very probably certain of them, bees, ants, termites, had to strive for thousands of centuries before they found the way to those state institutions, that division of functions, those restrictions upon individuals, which we admire them for today. It is characteristic of our present state that we know by our own feelings that we should not think ourselves happy in any of these communities of the animal world, or in any of the rôles they delegate to individuals. With other animal species it may be that a temporary deadlock has been reached between the influences of their

<sup>3</sup> And we may probably add more precisely that its form was necessarily determined after some definite event which still remains to be discovered.

environment and the instincts contending with them, so that a cessation of development has taken place. In primitive man, a fresh access of libido may have kindled a new spurt of energy on the part of the instinct of destruction. There are a great many questions in all this to which as yet we have no answer.

Another question concerns us more closely now. What means does civilization make use of to hold in check the aggressiveness that opposes it, to make it harmless, perhaps to get rid of it? Some of these measures we have already come to know, though not yet the one that is apparently the most important. We can study it in the evolution of the individual. What happens in him to render his craving for aggression innocuous? Something very curious, that we should never have guessed and that yet seems simple enough. The aggressiveness is introjected, *internalized*; in fact, it is sent back where it came from, i.e., directed against the ego. It is there taken over by a part of the ego that distinguishes itself from the rest as a super-ego, and now, in the form of *conscience*, exercises the same propensity to harsh aggressiveness against the ego that the ego would have liked to enjoy against others. The tension between the strict super-ego and the subordinate ego we call the *sense of guilt*; it manifests itself as the need for punishment. Civilization, therefore, obtains the mastery over the dangerous love of aggression in individuals by enfeebling and disarming it and setting up an institution within their minds to keep watch over it, like a garrison in a conquered city.

As to the origin of the sense of guilt, analysts have different views from those of the psychologists; nor is it easy for analysts to explain it either. First of all, when one asks how a sense of guilt arises in anyone, one is told something one cannot dispute: people feel guilty (pious people call it "sinful") when they have done something they know to be *bad*. But then one sees how little this answer tells one. Perhaps, after some hesitation, one will add that a person who has not actually committed a bad act, but has merely become aware of the intention to do so, can also hold himself guilty; and then one will ask why in this case the intention is counted as equivalent to the deed. In both cases, however, one is presupposing that wickedness has already been recognized as reprehensible, as something that ought not to be put into execution. How is this judgment arrived at? One may reject the suggestion of an original—as one might say, natural—capac-

ity for discriminating between good and evil. Evil is often not at all that which would injure or endanger the ego; on the contrary, it can also be something that it desires, that would give it pleasure. An extraneous influence is evidently at work; it is this that decides what is to be called good and bad. Since their own feelings would not have led men along the same path, they must have had a motive for obeying this extraneous influence. It is easy to discover this motive in man's helplessness and dependence upon others; it can best be designated the *dread of losing love*. If he loses the love of others on whom he is dependent, he will forfeit also their protection against many dangers, and above all he runs the risk that this stronger person will show his superiority in the form of punishing him. What is bad is, therefore, to begin with, whatever causes one to be threatened with a loss of love; because of the dread of this loss, one must desist from it. That is why it makes little difference whether one has already committed the bad deed or only intends to do so; in either case the danger begins only when the authority has found it out, and the latter would behave in the same way in both cases.

We call this state of mind a *bad conscience* but actually it does not deserve this name, for at this stage the sense of guilt is obviously only the dread of losing love, *social anxiety*. In a little child it can never be anything else, but in many adults too it has only changed in so far as the larger human community takes the place of the father or of both parents. Consequently, such people habitually permit themselves to do any bad deed that procures them something they want, if only they are sure that no authority will discover it or make them suffer for it; their anxiety relates only to the possibility of detection.<sup>1</sup> Present-day society has to take into account the prevalence of this state of mind.

A great change takes place as soon as the authority has been internalized by the development of a super-ego. The manifestations of conscience are then raised to a new level; to be accurate, one should not call them conscience and sense of guilt before this.<sup>2</sup> At this point

<sup>1</sup> One is reminded of Rousseau's famous mandarin!

<sup>2</sup> Every reasonable person will understand and take into account that in this descriptive survey things that in reality occur by gradual transitions are sharply differentiated and that the mere existence of a super-ego is not the only factor concerned, but also its relative strength and sphere of influence. All that has been said above in regard to conscience and guilt, moreover, is common knowledge and practically undisputed.

the dread of discovery ceases to operate and also once for all any difference between doing evil and wishing to do it, since nothing is hidden from the super-ego, not even thoughts. The real seriousness of the situation has vanished, it is true: for the new authority, the super-ego, has no motive, as far as we know, for ill-treating the ego with which it is itself closely bound up. But the influence of the genetic derivation of these things, which causes what has been outlived and surmounted to be re-lived, manifests itself so that on the whole things remain as they were at the beginning. The super-ego torments the sinful ego with the same feelings of dread and watches for opportunities whereby the outer world can be made to punish it.

At this second stage of development, conscience exhibits a peculiarity which was absent in the first and is not very easy to account for. That is, the more righteous a man is, the stricter and more suspicious will his conscience be, so that ultimately it is precisely those people who have carried holiness farthest who reproach themselves with the deepest sinfulness. This means that virtue forfeits some of her promised reward; the submissive and abstemious ego does not enjoy the trust and confidence of its mentor, and, as it seems, strives in vain to earn it. Now, to this some people will be ready to object that these difficulties are artificialities. A relatively strict and vigilant conscience is the very sign of a virtuous man, and though saints may proclaim themselves sinners, they are not so wrong, in view of the temptations of instinctual gratifications to which they are peculiarly liable—since, as we know, temptations do but increase under constant privation, whereas they subside, at any rate temporarily, if they are sometimes gratified. The field of ethics is rich in problems, and another of the facts we find here is that misfortune, i.e., external deprivation, greatly intensifies the strength of conscience in the super-ego. As long as things go well with a man, his conscience is lenient and lets the ego do all kinds of things; when some calamity befalls, he holds an inquisition within, discovers his sin, heightens the standards of his conscience, imposes abstinences on himself and punishes himself with penances.<sup>1</sup> Whole peoples have

acted in this way and still do so. But this is easily explained from the original infantile stage of conscience which, as we thus see, is not abandoned after the introjection into the super-ego, but persists alongside and behind the latter. Fate is felt to be a substitute for the agency of the parents: adversity means that one is no longer loved by this highest power of all, and, threatened by this loss of love, one humbles oneself again before the representative of the parents in the super-ego which in happier days one had tried to disregard. This becomes especially clear when destiny is looked upon in the strictly religious sense as the expression of God's will and nothing else. The people of Israel believed themselves to be God's favourite children, and when the great Father hurled visitation after visitation upon them, it still never shook them in this belief or caused them to doubt His power and His justice; they proceeded instead to bring their prophets into the world to declare their sinfulness to them and out of their sense of guilt they constructed the stringent commandments of their priestly religion. It is curious how differently a savage behaves! If he has had bad fortune, he does not throw the blame on himself, but on his fetish, who has plainly not done his duty by him, and he belabours it instead of punishing himself.

Hence we know of two sources for feelings of guilt: that arising from the dread of authority and the later one from the dread of the super-ego. The first one compels us to renounce instinctual gratification; the other presses over and above this towards punishment, since the persistence of forbidden wishes cannot be concealed from the super-ego. We have also heard how the severity of the super-ego, the rigour of conscience, is to be explained. It simply carries on the severity of external authority which it has succeeded and to some extent replaced. We see now how renunciation of instinctual gratification is related to the sense of guilt. Originally, it is true, renunciation is the consequence of a dread of external authority; one gives up pleasures so as not to lose its love. Having made this renunciation, one is quits with authority, so to speak; no feeling of guilt should remain. But with the dread of the super-ego the case is different. Renunciation of gratification does not suffice here, for the wish persists and is not capable of being hidden from the super-ego. In spite of the renunciations made, feelings of guilt will be experienced and this is a great disadvantage economically of the erection of the super-ego, or, as one may say,

<sup>1</sup> This increased sensitivity of morals in consequence of ill-luck has been illustrated by Mark Twain in a delicious little story: *The First Melon I ever Stole*. This melon, as it happened, was unripe. I heard Mark Twain tell the story himself in one of his lectures. After he had given out the title, he stopped and asked himself in a doubtful way: "Was it the first?" This was the whole story.

of the formation of conscience. Renunciation no longer has a completely absolving effect; virtuous restraint is no longer rewarded by the assurance of love; a threatened external unhappiness—loss of love and punishment meted out by external authority—has been exchanged for a lasting inner unhappiness, the tension of a sense of guilt.

These inter-relations are so complicated and at the same time so important that, in spite of the dangers of repetition, I will consider them again from another angle. The chronological sequence would thus be as follows: first, instinct-renunciation due to dread of an aggression by external authority—this is, of course, tantamount to the dread of loss of love, for love is a protection against these punitive aggressions. Then follows the erection of an internal authority, and instinctual renunciation due to dread of it—that is, dread of conscience. In the second case, there is the equivalence of wicked acts and wicked intentions; hence comes the sense of guilt, the need for punishment. The aggressiveness of conscience carries on the aggressiveness of authority. Thus far all seems to be clear; but how can we find a place in this scheme for the effect produced by misfortune (i.e., renunciations externally imposed), for the effect it has of increasing the rigour of conscience? How account for the exceptional stringency of conscience in the best men, those least given to rebel against it? We have already explained both these peculiarities of conscience, but probably we still have an impression that these explanations do not go to the root of the matter, and that they leave something still unexplained. And here at last comes in an idea which is quite peculiar to psycho-analysis and alien to ordinary ways of thinking. Its nature enables us to understand why the whole matter necessarily seemed so confused and obscure to us. It tells us this: in the beginning conscience (more correctly, the anxiety which later became conscience) was the cause of instinctual renunciation, but later this relation is reversed. Every renunciation then becomes a dynamic fount of conscience; every fresh abandonment of gratification increases its severity and intolerance; and if we could only bring it better into harmony with what we already know about the development of conscience, we should be tempted to make the following paradoxical statement: Conscience is the result of instinctual renunciation, or: Renunciation (externally imposed) gives rise to conscience, which then demands further renunciations.

The contradiction between this proposition and our previous knowledge about the genesis of conscience is not in actual fact so very great, and we can see a way in which it may be still further reduced. In order to state the problem more easily, let us select the example of the instinct of aggression, and let us suppose that the renunciation in question is always a renunciation of aggression. This is, of course, merely a provisional assumption. The effect of instinctual renunciation on conscience then operates as follows: every impulse of aggression which we omit to gratify is taken over by the super-ego and goes to heighten its aggressiveness (against the ego). It does not fit in well with this that the original aggressiveness of conscience should represent a continuance of the rigour of external authority, and so have nothing to do with renunciation. But we can get rid of this discrepancy if we presume a different origin for the first quantum of aggressiveness with which the super-ego was endowed.

When authority prevented the child from enjoying the first but most important gratifications of all, aggressive impulses of considerable intensity must have been evoked in it, irrespective of the particular nature of the instinctual deprivations concerned. The child must necessarily have had to give up the satisfaction of these revengeful aggressive wishes. In this situation, in which it is economically so hard pressed, it has recourse to certain mechanisms well known to us; by the process of identification it absorbs into itself the invulnerable authority, which then becomes the super-ego and comes into possession of all the aggressiveness which the child would gladly have exercised against it. The child's ego has to content itself with the unhappy rôle of the authority—the father—who has been thus degraded. It is, as so often, a reversal of the original situation, "If I were father and you my child, I would treat *you* badly." The relation between super-ego and ego is a reproduction, distorted by a wish, of the real relations between the ego, before it was subdivided, and an external object. That is also typical. The essential difference, however, is that the original severity of the super-ego does not—or not so much—represent the severity which has been experienced or anticipated from the object, but expresses the child's own aggressiveness towards the latter. If this is correct, one could truly assert that conscience is formed in the beginning from the suppression of an aggressive impulse

and strengthened as time goes on by each fresh suppression of the kind.

Now, which of these two theories is the true one? The earlier, which seemed genetically so unassailable, or the new one, which rounds off our theories in such a welcome manner? Clearly, they are both justified, and by the evidence, too, of direct observation; they do not contradict each other, and even coincide at one point, for the child's revengeful aggressiveness will be in part provoked by the amount of punishing aggression that it anticipates from the father. Experience has shown, however, that the severity which a child's super-ego develops in no way corresponds to the severity of the treatment it has itself experienced.<sup>1</sup> It seems to be independent of the latter; a child which has been very leniently treated can acquire a very strict conscience. But it would also be wrong to exaggerate this independence; it is not difficult to assure oneself that strict upbringing also has a strong influence on the formation of a child's super-ego. It comes to this, that the formation of the super-ego and the development of conscience are determined in part by innate constitutional factors and in part by the influence of the actual environment; and that is in no way surprising—on the contrary, it is the invariable aetiological condition of all such processes.<sup>2</sup>

It may also be said that when a child reacts to the first great instinctual deprivations with an excessive aggressiveness and a corresponding strictness of its super-ego, it is thereby following a phylogenetic prototype, unheeding of what reaction would in reality be justified; for the father of primitive times was certainly terrifying, and one may safely attribute the utmost degree of aggressiveness to him. The differences between the two theories of the genesis of conscience are thus still further di-

minished, if one passes from individual to phylogenetic development. But then, on the other hand, we find a new important difference between the two processes. We cannot disregard the conclusion that man's sense of guilt has its origin in the Oedipus complex and was acquired when the father was killed by the association of the brothers. At that time the aggression was not suppressed but carried out, and it is this same act of aggression whose suppression in the child we regard as the source of feelings of guilt. Now, I should not be surprised if a reader were to cry out angrily: "So it makes no difference whether one does kill one's father or does not, one gets a feeling of guilt in either case! Here I should think one may be allowed some doubts. Either it is not true that guilt is evoked by suppressed aggressiveness or else the whole story about the father-murder is a romance, and primeval man did not kill his father any more often than people do nowadays. Besides this, if it is not a romance but a plausible piece of history, it would only be an instance of what we all expect to happen, namely, that one feels guilty because one has really done something which cannot be justified. And what we are all waiting for is for psycho-analysis to give us an explanation of this reaction, which at any rate is something that happens every day."

This is true, and we must make good the omission. There is no great mystery about it either. When one has feelings of guilt after one has committed some crime and because of it, this feeling should more properly be called *remorse*. It relates only to the one act, and clearly it presupposes that *conscience*, the capacity for feelings of guilt, was already in existence before the deed. Remorse of this kind can, therefore, never help us to find out the source of conscience and feelings of guilt in general. In these everyday instances the course of events is usually as follows: an instinctual need acquires the strength to achieve fulfilment in spite of conscience, the strength of which also has its limits, whereupon the inevitable reduction of the need after satisfaction restores the earlier balance of forces. Psycho-analysis is quite justified, therefore, in excluding the case of a sense of guilt through remorse from this discussion, however frequently it may occur and however great its importance may be practically.

But if man's sense of guilt goes back to the murder of the father, that was undoubtedly an instance of *remorse*, and yet are we to suppose

<sup>1</sup> As has rightly been emphasized by Melanie Klein and other English writers.

<sup>2</sup> In his *Psychoanalyse der Gesamtpersönlichkeit*, 1927, Franz Alexander has, in connection with Aichhorn's study of dissocial behaviour in children, discussed the two main types of pathogenic methods of training, that of excessive severity and of spoiling. The *unduly lenient and indulgent* father fosters the development of an over-strict super-ego because, in face of the love which is showered on it, the child has no other way of disposing of its aggressiveness than to turn it inwards. In neglected children who grow up without any love, the tension between ego and super-ego is lacking; their aggressions can be directed externally. Apart from any constitutional factor which may be present, therefore, one may say that a strict conscience arises from the co-operation of two factors in the environment: the deprivation of instinctual gratification which evokes the child's aggressiveness, and the love it receives which turns this aggressiveness inwards, where it is taken over by the super-ego.

that there were no conscience and feelings of guilt before the act on that occasion? If so, where did the remorse come from then? This instance must explain to us the riddle of the sense of guilt and so make an end of our difficulties. And it will do so, as I believe. This remorse was the result of the very earliest primal ambivalence of feelings towards the father: the sons hated him, but they loved him too; after their hate against him had been satisfied by their aggressive acts, their love came to expression in their remorse about the deed, set up the super-ego by identification with the father, gave it the father's power to punish as he would have done the aggression they had performed, and created the restrictions which should prevent a repetition of the deed. And since impulses to aggressions against the father were repeated in the next generations, the feelings of guilt, too, persisted, and were further reinforced every time an aggression was suppressed anew and made over to the super-ego. At this point, it seems to me, we can at last clearly perceive the part played by love in the origin of conscience and the fatal inevitableness of the sense of guilt. It is not really a decisive matter whether one has killed one's father or abstained from the deed; one must feel guilty in either case, for guilt is the expression of the conflict of ambivalence, the eternal struggle between Eros and the destructive or death instinct. This conflict is engendered as soon as man is confronted with the task of living with his fellows; as long as he knows no other form of life in common but that of the family, it must express itself in the Oedipus complex, cause the development of conscience, and create the first feelings of guilt. When mankind tries to institute wider forms of communal life, the same conflict continues to arise—in forms derived from the past—and intensified so that a further reinforcement of the sense of guilt results. Since culture obeys an inner erotic impulse which bids it bind mankind into a closely-knit mass, it can achieve this aim only by means of its vigilance in fomenting an ever-increasing sense of guilt. That which began in relation to the father ends in relation to the community. If civilization is an inevitable course of development from the group of the family to the group of humanity as a whole, then an intensification of the sense of guilt—resulting from the innate conflict of ambivalence, from the eternal struggle between the love and the death trends—will be inextricably bound up with it, until perhaps the

sense of guilt may swell to a magnitude that individuals can hardly support. One is reminded of the telling accusation made by the great poet against the *heavenly forces*:

*Ye set our feet on this life's road,  
Ye watch our guilty, erring courses,  
Then leave us, bowed beneath our load,  
For earth its every debt enforces.<sup>1</sup>*

And one may heave a sigh at the thought that it is vouchsafed to a few, with hardly an effort, to salve from the whirlpool of their own emotions the deepest truths, to which we others have to force our way, ceaselessly groping amid torturing uncertainties.

### VIII

ON reaching the end of such a journey as this, the author must beg his readers to pardon him for not having been a more skilful guide, not sparing them bleak stretches of country at times and laborious detours at others. There is no doubt that it could have been done better. I will now try to make some amends.

First of all, I suspect the reader feels that the discussion about the sense of guilt oversteps its proper boundaries in this essay and takes up too much space so that the rest of the subject-matter, which is not always closely connected with it, gets pushed to one side. This may have spoilt the composition of the work; but it faithfully corresponds to my intention to represent the sense of guilt as the most important problem in the evolution of culture, and to convey that the price of progress in civilization is paid in forfeiting happiness through the heightening of the sense of guilt.<sup>2</sup> What sounds puzzling in this statement, which is the final conclusion of our whole investigation, is probably due to the quite peculiar relation—as yet completely unexplained—

<sup>1</sup> Goethe, *Wilhelm Meister*, "The Song of the Harper."

<sup>2</sup> "Thus conscience does make cowards of us all. . . ." That the upbringing of young people at the present day conceals from them the part sexuality will play in their lives is not the only reproach we are obliged to bring against it. It offends too in not preparing them for the aggressions of which they are destined to become the objects. Sending the young out into life with such a false psychological orientation is as if one were to equip people going on a Polar expedition with summer clothing and maps of the Italian lakes. One can clearly see that ethical standards are being misused in a way. The strictness of these standards would not do much harm if education were to say: "This is how men ought to be in order to be happy and make others happy, but you have to reckon with their not being so." Instead of this the young are made to believe that everyone else conforms to the standard of ethics, i.e., that everyone else is good. And then on this is based the demand that the young shall be so too.

the sense of guilt has to our consciousness. In the common cases of remorse which we think normal, it becomes clearly perceptible to consciousness; indeed, we often speak of *consciousness of guilt* instead of sense of guilt. In our study of the neuroses, in which we have found invaluable clues towards an understanding of normal people, we find some very contradictory states of affairs in this respect. In one of these maladies, the obsessional neurosis, the sense of guilt makes itself loudly heard in consciousness; it dominates the clinical picture as well as the patient's life and lets hardly anything else appear alongside of it. But in most of the other types and forms of neurosis it remains completely unconscious, without its effect being any less great, however. Our patients do not believe us when we ascribe an *unconscious sense of guilt* to them; in order to become even moderately intelligible to them, we have to explain that the sense of guilt expresses itself in an unconscious seeking for punishment. But its connection with the form of the neurosis is not to be over-estimated; even in the obsessional neurosis there are people who are not aware of their sense of guilt or who perceive it only as a tormenting uneasiness or kind of anxiety and then not until they are prevented from carrying out certain actions. We ought some day to be able at last to understand these things; as yet we cannot. Here perhaps is the place to remark that at bottom the sense of guilt is nothing but a topographical variety of anxiety, and that in its later phases it coincides completely with the dread of the super-ego. The relation of anxiety to consciousness, moreover, is characterized by the same extraordinary variations. Somewhere or other there is always anxiety hidden behind all symptoms; at one moment, however, it sweeps into consciousness, drowning everything else with its clamour, and at the next it secretes itself so completely that we are forced to speak of unconscious anxiety—or if we want to have a cleaner conscience psychologically, since anxiety is after all only a perception—of possibilities of anxiety. Consequently it is very likely that the sense of guilt produced by culture is not perceived as such and remains to a great extent unconscious, or comes to expression as a sort of uneasiness or discontent for which other motivations are sought. The different religions, at any rate, have never overlooked the part played by the sense of guilt in civilization. What is more, they come forward with a claim,

which I have not considered elsewhere,<sup>1</sup> to save mankind from this sense of guilt, which they call *sin*. We indeed have drawn our conclusions, from the way in which in Christianity this salvation is won—the sacrificial death of one who therewith takes the whole of the common guilt of all upon himself—about the occasion on which this primal sense of guilt was first acquired, that is, the occasion which was also the inception of culture.<sup>2</sup>

It will not be very important, but it may be just as well to go more precisely into the meaning of certain words like *super-ego*, *conscience*, *sense of guilt*, *need for punishment*, *remorse*, which we have perhaps often used too loosely and in place of one another. They all relate to the same situation, but they denote different aspects of it. The *super-ego* is an agency or institution in the mind whose existence we have inferred: *Conscience* is a function we ascribe, among others, to the super-ego; it consists of watching over and judging the actions and intentions of the ego, exercising the functions of a censor. The *sense of guilt*, the severity of the super-ego, is therefore the same thing as the rigour of conscience; it is the perception the ego has that it is watched in this way, the ego's appreciation of the tension between its strivings and the standards of the super-ego; and the anxiety that lies behind all these relations, the dread of that critical institution, the *need for punishment*, is an instinctual manifestation on the part of the ego, which has become masochistic under the influence of the sadistic super-ego, i.e., which has brought a part of the instinct of destruction at work within itself into the service of an erotic attachment to the super-ego. We ought not to speak of conscience before a super-ego is demonstrable; as to consciousness of guilt, we must admit that it comes into being before the super-ego, therefore before conscience. At that time is is the direct expression of the dread of external authority, the recognition of the tension between the ego and this latter; it is the direct derivative of the conflict between the need for parental love and the urgency towards instinctual gratification, and it is the thwarting of this urgency that provokes the tendency to aggression. It is because these two different versions of the sense of guilt—one arising from dread of the external and the other from dread of the inner authority—are superimposed one on the other that our

<sup>1</sup> I mean in *The Future of an Illusion*.

<sup>2</sup> *Totem and Taboo* (1912).

insight into the relations of conscience has been hampered in so many ways. *Remorse* is a general term denoting the ego's reaction under a special form of the sense of guilt; it includes the almost unaltered sensory material belonging to the anxiety that is at work behind the sense of guilt; it is itself a punishment and may include the need for punishment; it too, therefore, may occur before conscience has developed.

Further, it will do no harm for us to review once more the contradictions which have confused us at times during our enquiries. The sense of guilt, we said at one point, was the consequence of uncommitted aggressions; but another time and, in particular, in the case of its historical beginning, the murder of the father, it was the consequence of an aggression that was carried out. We also found a way out of this difficulty. The development of the inner authority, the super-ego, was precisely what radically altered the whole situation. Before this, the sense of guilt coincided with remorse; we observe, in saying this, that the term *remorse* is to be reserved for the reaction after an actual performance of an aggressive deed. After this, the omniscience of the super-ego robbed the distinction between intended aggressions and aggressions committed of its significance; a mere intention to commit an act of violence could then evoke a sense of guilt—as psycho-analysis has found—as well as one which has actually been committed—as all the world knows. The conflict of ambivalence between the two primal instincts leaves the same impress on the psychological situation, irrespective of the change that has taken place in this. A temptation arises to look here for an explanation of the mystery of the varying relation between the sense of guilt and consciousness. The sense of guilt which is due to remorse for an evil deed must always have been conscious; that due to a perception of an evil impulse could have remained unconscious. But it cannot be as simple as that: the obsessional neurosis contradicts it emphatically. The second contradiction was that the aggressive energy with which one imagined the super-ego to be endowed was, according to one view, merely a continuation of the punitive energy belonging to external authority, preserved within the mind; whereas according to another view it consisted, on the contrary, of aggressive energy originating in the self, levelled against this inhibiting authority but not allowed to discharge itself in actions. The first view seemed to

accord better with the history of the sense of guilt, the second with the theory of it. More searching reflection has resolved this apparently irreconcilable contradiction almost too completely; what remained as essential and common to both was that in both cases we were dealing with an aggression that had been turned inward. Clinical observation, moreover, really permits us to distinguish two sources for the aggressiveness we ascribe to the super-ego, each of which in any given case may be operating predominantly, but which usually are both at work together.

This, I think, is the place to suggest that a proposal which I previously put forward as a provisional assumption should be taken in earnest. In the latest analytical literature,<sup>1</sup> a predilection has been shown for the view that any kind of privation, any thwarted instinctual gratification, results in a heightening of the sense of guilt, or may do so. I believe one obtains a great simplification of theory if one regards this as valid *only* for the aggressive instincts, and that little will be found to contradict this assumption. How then is it to be explained dynamically and economically that a heightening of the sense of guilt should appear in place of an unfulfilled erotic desire? This can surely only happen in a roundabout way: the thwarting of the erotic gratification provokes an access of aggressiveness against the person who interfered with the gratification, and then this tendency to aggression in its turn has itself to be suppressed. So then it is, after all, only the aggression which is changed into guilt, by being suppressed and made over to the super-ego. I am convinced that very many processes will admit of much simpler and clearer explanation if we restrict the findings of psycho-analysis in respect of the origin of the sense of guilt to the aggressive instincts. Reference to the clinical material here gives us no unequivocal answer, because, according to our own hypothesis, the two kinds of instincts hardly ever appear in a pure form, unmixed with each other; but the investigation of extreme cases would probably point in the direction I anticipate. I am tempted to extract our first advantage from this narrower conception by applying it to the repression-process. The symptoms of neurosis, as we have learned, are essentially substitutive gratifications for unfulfilled sexual wishes. In the course of our ana-

<sup>1</sup> In particular, in contributions by Ernest Jones, Susan Isaacs, Melanie Klein; also, as I understand, in those of Reik and Alexander.

lytic work we have found to our surprise that perhaps every neurosis masks a certain amount of unconscious sense of guilt, which in its turn reinforces the symptoms by exploiting them as punishment. One is now inclined to suggest the following statement as a possible formulation: when an instinctual trend undergoes repression, its libidinal elements are transformed into symptoms and its aggressive components into a sense of guilt. Even if this statement is only accurate as an approximation, it merits our interest.

Some readers of this essay, too, may be under the impression that the formula of the struggle between Eros and the death instinct has been reiterated too often. It is supposed to characterize the cultural process which evolves in humanity; but it has been related also to the development of the individual, and, besides this, is supposed to have revealed the secret of organic life in general. It becomes necessary for us to examine the relation of these three processes to one another. Now, the repetition of the same formula is vindicated by the consideration that the cultural processes, both in humanity and in the development of an individual, are life-processes; consequently they must both partake of the most universal characteristic of life. On the other hand, evidence of the presence of this universal characteristic does not help us to discriminate, unless it is further narrowed down by special qualifications. We can therefore set our minds at rest only if we say that the cultural process is the particular modification undergone by the life-process under the influence of the task set before it by Eros and stimulated by Ananke, external necessity; and this task is that of uniting single human beings into a larger unity with libidinal attachments between them. When, however, we compare the cultural process in humanity with the process of development or upbringing in an individual human being, we shall conclude without much hesitation that the two are very similar in nature, if not in fact the same process applied to a different kind of object. The civilizing process in the human species is naturally more of an abstraction than the development of an individual, and therefore harder to apprehend in concrete terms, nor should the discovery of analogies be pushed to extremes; but in view of the similar character of the aims of the two processes—in one the incorporation of an individual as a member of a group and in the other the creation of a single group out of

many individuals—the similarity of the means employed and of the results obtained in the two cases is not surprising. In view of its exceptional importance, we must no longer postpone mention of one feature differentiating the two processes. The development of the individual is ordered according to the program laid down by the pleasure-principle, namely, the attainment of happiness, and to this main objective it holds firmly; the incorporation of the individual as a member of a community, or his adaptation to it, seems like an almost unavoidable condition which has to be filled before he can attain this objective of happiness. If he could achieve it without fulfilling this condition, it would perhaps be better. To express it differently, we may say: Individual development seems to us a product of the interplay of two trends, the striving for happiness, generally called *egoistic*, and the impulse towards merging with others in the community, which we call *altruistic*. Neither of these descriptions goes far beneath the surface. In individual development, as we have said, the main accent falls on the egoistic trend, the striving for happiness; while the other tendency, which may be called the *cultural* one, usually contents itself with instituting restrictions. But things are different in the development of culture: here far the most important aim is that of creating a single unity out of individual men and women, while the objective of happiness, though still present, is pushed into the background; it almost seems as if humanity could be most successfully united into one great whole if there were no need to trouble about the happiness of individuals. The process of development in individuals must therefore be admitted to have its special features which are not repeated in the cultural evolution of humanity; the two processes only necessarily coincide in so far as the first also includes the aim of incorporation into the community.

Just as a planet circles round its central body, while at the same time rotating on its own axis, so the individual man takes his part in the course of humanity's development as he goes on his way through life. But to our dull eyes the play of forces in the heavens seems set fast in a never-varying scheme, though in organic life we can still see how the forces contend with one another and the results of the conflict change from day to day. So in every individual the two trends, one towards personal happiness and the other towards unity with the

rest of humanity, must contend with each other; so must the two processes of individual and of cultural development oppose each other and dispute the ground against each other. This struggle between individual and society, however, is not derived from the antagonism of the primal instincts, Eros and death, which are probably irreconcilable; it is a dissension in the camp of the libido itself, comparable to the contest between the ego and its objects for a share of the libido; and it does eventually admit of a solution in the individual, as we may hope it will also do in the future of civilization—however greatly it may oppress the lives of individuals at the present time.

The analogy between the process of cultural evolution and the path of individual development may be carried further in an important respect. It can be maintained that the community, too, develops a super-ego, under whose influence cultural evolution proceeds. It would be an enticing task for an authority on human systems of culture to work out this analogy in specific cases. I will confine myself to pointing out certain striking details. The super-ego of any given epoch of civilization originates in the same way as that of an individual; it is based on the impression left behind them by great leading personalities, men of outstanding force of mind, or men in whom some one human tendency has developed in unusual strength and purity, often for that reason very disproportionately. In many instances the analogy goes still further, in that during their lives—often enough, even if not always—such persons are ridiculed by others, ill-used, or even cruelly done to death, just as happened with the primal father who also rose again to become a deity long after his death by violence. The most striking example of this double fate is the figure of Jesus Christ, if indeed it does not itself belong to the realm of mythology which called it into being out of a dim memory of that primordial event. Another point of agreement is that the cultural super-ego, just like that of an individual, sets up high ideals and standards, and that failure to fulfil them is punished by both with *anxiety of conscience*. In this particular, indeed, we come across the remarkable circumstance that the mental processes concerned here are actually more familiar to us and more accessible to consciousness when they proceed from the group than they can be in the individual. In the latter, when tension arises, the aggressions of the super-ego voicing its noisy reproaches are all that is per-

ceived, while its injunctions themselves often remain unconscious in the background. If we bring them to the knowledge of consciousness, we find that they coincide with the demands of the prevailing cultural super-ego. At this point the two processes, that of the evolution of the group and the development of the individual, are always firmly mortised together, so to speak. Consequently many of the effects and properties of the super-ego can be more easily detected through its operations in the group than in the individual.

The cultural super-ego has elaborated its ideals and erected its standards. Those of its demands which deal with the relations of human beings to one another are comprised under the name of *ethics*. The greatest value has at all times been set upon systems of ethics, as if men had expected them in particular to achieve something especially important. And ethics does in fact deal predominantly with the point which is easily seen to be the sorest of all in any scheme of civilization. Ethics must be regarded, therefore, as a therapeutic effort: as an endeavour to achieve something through the standards imposed by the super-ego which had not been attained by the work of civilization in other ways. We already know—it is what we have been discussing—that the question is how to dislodge the greatest obstacle to civilization, the constitutional tendency in men to aggressions against one another; and for that very reason the commandment to love one's neighbour as oneself—probably the most recent of the cultural super-ego's demands—is especially interesting to us. In our investigations and our therapy of the neuroses we cannot avoid finding fault with the super-ego of the individual on two counts: in commanding and prohibiting with such severity it troubles too little about the happiness of the ego, and it fails to take into account sufficiently the difficulties in the way of obeying it—the strength of instinctual cravings in the id and the hardships of external environment. Consequently, in our therapy we often find ourselves obliged to do battle with the super-ego and work to moderate its demands. Exactly the same objections can be made against the ethical standards of the cultural super-ego. It, too, does not trouble enough about the mental constitution of human beings; it enjoins a command and never asks whether or not it is possible for them to obey it. It presumes, on the contrary, that a man's ego is psychologically capable of anything that is required of it—that his ego has

unlimited power over his id. This is an error; even in so-called normal people the power of controlling the id cannot be increased beyond certain limits. If one asks more of them, one produces revolt or neurosis in individuals or makes them unhappy. The command to love our neighbours as ourselves is the strongest defence there is against human aggressiveness and it is a superlative example of the unpsychological attitude of the cultural super-ego. The command is impossible to fulfil; such an enormous inflation of love can only lower its value and not remedy the evil. Civilization pays no heed to all this; it merely prates that the harder it is to obey the more laudable the obedience. The fact remains that anyone who follows such preaching in the present state of civilization only puts himself at a disadvantage beside all those who set it at naught. What an overwhelming obstacle to civilization aggression must be if the defence against it can cause as much misery as aggression itself! *Natural* ethics, as it is called, has nothing to offer here beyond the narcissistic satisfaction of thinking oneself better than others. The variety of ethics that links itself with religion brings in at this point its promises of a better future life. I should imagine that as long as virtue is not rewarded in this life ethics will preach in vain. I too think it unquestionable that an actual change in men's attitude to property would be of more help in this direction than any ethical commands; but among the Socialists this proposal is obscured by new idealistic expectations disregarding human nature, which detract from its value in actual practice.

It seems to me that the point of view which seeks to follow the phenomena of cultural evolution as manifestations of a super-ego promises to yield still further discoveries. I am coming quickly to an end. There is one question, however, which I can hardly ignore. If the evolution of civilization has such a far-reaching similarity with the development of an individual, and if the same methods are employed in both, would not the diagnosis be justified that many systems of civilization—or epochs of it—possibly even the whole of humanity—have become *neurotic* under the pressure of the civilizing trends? To analytic dissection of these neuroses, therapeutic recommendations might follow which could claim a great practical interest. I would not say that such an attempt to apply psychoanalysis to civilized society would be fanciful or doomed to fruitlessness. But it behooves us

to be very careful, not to forget that after all we are dealing only with analogies, and that it is dangerous, not only with men but also with concepts, to drag them out of the region where they originated and have matured. The diagnosis of collective neuroses, moreover, will be confronted by a special difficulty. In the neurosis of an individual we can use as a starting-point the contrast presented to us between the patient and his environment which we assume to be *normal*. No such background as this would be available for any society similarly affected; it would have to be supplied in some other way. And with regard to any therapeutic application of our knowledge, what would be the use of the most acute analysis of social neuroses, since no one possesses power to compel the community to adopt the therapy? In spite of all these difficulties, we may expect that one day someone will venture upon this research into the pathology of civilized communities.

For various reasons, it is very far from my intention to express any opinion concerning the value of human civilization. I have endeavoured to guard myself against the enthusiastic partiality which believes our civilization to be the most precious thing that we possess or could acquire, and thinks it must inevitably lead us to undreamed-of heights of perfection. I can at any rate listen without taking umbrage to those critics who aver that when one surveys the aims of civilization and the means it employs, one is bound to conclude that the whole thing is not worth the effort and that in the end it can only produce a state of things which no individual will be able to bear. My impartiality is all the easier to me since I know very little about these things and am sure only of one thing, that the judgments of value made by mankind are immediately determined by their desires for happiness: in other words, that those judgments are attempts to prop up their illusions with arguments. I could understand it very well if anyone were to point to the inevitable nature of the process of cultural development and say, for instance, that the tendency to institute restrictions upon sexual life, or to carry humanitarian ideals into effect at the cost of natural selection, are developmental trends which it is impossible to avert or divert, and to which it is best for us to submit as though they were natural necessities. I know, too, the objection that can be raised against this: that tendencies such as these, which are believed to have insuperable

power behind them, have often in the history of man been thrown aside and replaced by others. My courage fails me, therefore, at the thought of rising up as a prophet before my fellow-men, and I bow to their reproach that I have no consolation to offer them; for at bottom this is what they all demand—the frenzied revolutionary as passionately as the most pious believer.

The fateful question of the human species seems to me to be whether and to what extent the cultural process developed in it will succeed in mastering the derangements of communal life caused by the human instinct of

aggression and self-destruction. In this connection, perhaps the phase through which we are at this moment passing deserves special interest. Men have brought their powers of subduing the forces of nature to such a pitch that by using them they could now very easily exterminate one another to the last man. They know this—hence arises a great part of their current unrest, their dejection, their mood of apprehension. And now it may be expected that the other of the two *heavenly forces*, eternal Eros, will put forth his strength so as to maintain himself alongside of his equally immortal adversary.

# New Introductory Lectures on Psycho-Analysis

## PREFACE

MY *Introductory Lectures on Psycho-Analysis*<sup>1</sup> were delivered in the two winter terms of 1915-16 and 1916-17, in one of the lecture-rooms of the Vienna Psychiatric Clinic, before an audience composed of members and students of every Faculty. The first half of the lectures were improvised, and written down immediately afterwards; the second half were composed during an intervening summer vacation in Salzburg, and were delivered word for word in the following winter. In those days I still possessed the gift of a phonographic memory.

In contradistinction to them, these new lectures have never been delivered. My age has in the meantime relieved me of the duty of marking my membership of the University—even though the relation is only a peripheral one—by giving lectures; and a surgical operation has rendered me incapable of addressing an audience. It is therefore only in imagination that I picture myself once more in the lecture-room as I write out what follows; it may help me not to forget my duty to the reader as I delve deeper into my subject.

The new lectures are in no way intended to take the place of the earlier ones. They do not compose an independent whole which could hope to find a circle of readers of its own; but they are continuations and supplements which fall into three groups in their relation to the earlier lectures. To the first group belong the new manipulations of themes which have already been dealt with fifteen years ago, but which demand further treatment on account of the deepening of our knowledge and the alteration of our views; this group consists, that is to say, of critical revisions. The two other groups contain actual enlargements of our field, in that they deal with matters which either did not

exist in psycho-analysis at the time of the first lectures, or about which too little was known at that time to justify a special chapter-heading. It cannot be avoided, but it is also not to be deplored, that some of the new lectures unite the characteristics of these groups.

I have, moreover, emphasized the dependence of these new lectures on the *Introductory Lectures* by numbering them in continuation of the old ones. Thus the first lecture in this book is called the Twenty-ninth. Once more, they offer to the analytic specialist little that is new, and they are addressed to that large group of educated persons to whom, let us hope, one can ascribe a benevolent, if cautious, interest in the special nature and discoveries of this young science. And this time again it has been my guiding purpose to make no sacrifice in favour of apparent simplicity, completeness and finality; not to hide any problems and not to deny the existence of gaps and uncertainties. In no other field of scientific work would it be necessary to insist upon the modesty of one's claims. In every other subject this is taken for granted; the public expect nothing else. No reader of a work on astronomy would feel disappointed and contemptuous of that science, if he were shown the point at which our knowledge of the universe melts into obscurity. Only in psychology is it otherwise; here the constitutional incapacity of men for scientific research comes into full view. It looks as though people did not expect from psychology progress in knowledge, but some other kind of satisfaction; every unsolved problem, every acknowledged uncertainty is turned into a ground of complaint against it.

Anyone who loves the science of the mind must accept these hardships as well.

FREUD

VIENNA Summer 1932

## LECTURE 29

### REVISION OF THE THEORY OF DREAMS

LADIES AND GENTLEMEN: After a silence of more than fifteen years, I have brought you

<sup>1</sup> A General Introduction to Psycho-Analysis, p. 449 above.

together again in order to discuss with you the new developments, or it may be improvements, which have taken place in psycho-analytic theory during the interval. From more than one point of view it is right and proper that we

should turn our attention, in the first place, to the theory of dreams. This theory occupies a peculiar position in the history of psycho-analysis; it marks a turning-point. With the theory of dreams, analysis passed from being a psycho-therapeutic method to being a psychology of the depths of human nature. Ever since then the theory of dreams has remained the most characteristic and the most peculiar feature of the young science, something which has no parallel in the rest of scientific knowledge, a new found land which has been reclaimed from the regions of Folklore and Mysticism. The strangeness of the ideas which are necessarily involved in it has made it into a shibboleth, the use of which distinguishes those who might become believers in psycho-analysis from those who are incapable of comprehending it. Speaking for myself, I always found it a thing I could hold on to during those difficult times when the unsolved problems of the neuroses used to confuse my inexperienced judgment. Whenever I began to have doubts about the correctness of my tentative conclusions, the moment I managed to translate a senseless and complicated dream into a clear and intelligible mental process in the dreamer, I felt, with renewed confidence, that I was on the right track.

It is therefore of especial interest for us to follow, in regard to this particular matter of the theory of dreams, what changes psycho-analysis has undergone during the interval I have mentioned, and what progress it has made in gaining appreciation and understanding from contemporary thought. I may as well tell you straight away that you will be disappointed in both directions.

Let us look through the volumes of the *Internationale Zeitschrift für (ärztliche) Psychoanalyse*, in which the most important work on our subject has appeared since 1913. In the earlier volumes you will find one recurring heading, "On the Interpretation of Dreams," under which will be a quantity of contributions on various points of dream-theory. But the further you go, the rarer such contributions become; this standing heading eventually disappears entirely. The analysts behave as though they had nothing more to say about the dream, as though the whole subject of dream-theory were finished and done with. If, on the other hand, you ask how much of the theory of dreams is accepted by outsiders, the numerous psychiatrists and psycho-theraputists who warm their pot of soup at our fire—without indeed being very grateful for our hospitality—the so-called

educated people who are in the habit of appropriating the more startling of the conclusions of science, the literati and the general public, then the answer is not very satisfactory. A few formulae are generally known, and, among them, several which we have never put forward, such as the statement that all dreams are of a sexual nature; but even such important things as the fundamental distinction between the manifest dream-content and the latent dream-thoughts, the view that anxiety dreams do not contradict the wish-fulfilling function of the dream, the impossibility of interpreting a dream unless one knows the relevant associations of the dreamer, and, above all, the recognition of the fact that the most important part of the dream is the dream-work, seem, every one of them, to be as far removed from the consciousness of the generality of mankind as they were thirty years ago. I myself have every reason to say this, because during that period I have received an enormous number of letters, in which the writers inscribe their dreams for interpretation, or ask for information about the nature of dreams. They declare that they have read the *Interpretation of Dreams*, and yet in every sentence they betray their lack of understanding of our dream-theory. That will not prevent our once more giving an account of what we know about dreams. You will remember that last time we devoted a whole group of lectures to showing how we have come to understand this hitherto unexplained psychic phenomenon.

Supposing some one, say a patient under analysis, tells us one of his dreams; then we assume that he has made one of those communications to us to which he committed himself when he entered on his analytical treatment. It is, of course, a communication which is insufficiently communicative, because a dream is, in itself, not a social utterance; it is not a means for making oneself understood. We have not, indeed, the least idea what the dreamer wishes to say, and he himself knows no better than ourselves. At the outset, we have to make a quick decision. On the one hand, the dream may be, as the non-analytical physicians assure us, an indication that the dreamer has slept badly, that not all the parts of his brain achieved a uniform state of rest, that certain regions of it endeavoured to go on working under the influence of unknown stimuli and could only do so in a very incomplete way. If that is the case, then we are quite right not to bother ourselves any longer over this psycho-

logically worthless product of nocturnal disturbance. For how could we expect from the investigation of such things to arrive at anything useful for our purposes? On the other hand, however—but it is clear that from the outset we have decided otherwise. We have—perhaps quite arbitrarily—made the assumption, put forward the postulate, that even this unintelligible dream must be a perfectly valid, sensible, and valuable psychic act, of which we can make use in the analysis, just like any other communication. Only the result of our attempt can show us whether we are right. If we are able to turn the dream into a valuable utterance of this kind, then we obviously have a chance of learning something new, and of obtaining information of such a sort as otherwise would remain inaccessible to us.

Now, however, the difficulties of our task, and the puzzling nature of our theme become apparent. How are we going to set about turning a dream into a normal communication, and how are we going to explain that a part of the utterance of our patient has taken on a form which is as unintelligible for him as for us?

You will observe, ladies and gentlemen, that this time I am not expounding the subject on genetic lines, but I am speaking dogmatically. The first thing we have to do is to lay the foundations of our new attitude towards the problem of the dream by introducing two new concepts and two new names. We call what one usually refers to as the dream, the dream-text or the *manifest* dream, and what we are looking for, what we, as it were, suspect to lie behind the dream, the *latent* dream-thoughts. Now we can express our two problems in the following way: we have got to turn the manifest dream into the latent dream, and we have to show how the latter became the former in the mental life of the dreamer. The first bit is a practical problem, it comes under the heading of *dream-interpretation*, and requires a technique; the second is a theoretical problem, its solution should be the explanation of the hypothetical *dream-work*, and can only be a theory. Both the technique of dream-interpretation and the theory of the dream-work have to be built up from the beginning.

Which bit shall we begin with? I think we should start with the technique of dream-interpretation. It has a clearer outline and will make a more vivid impression on you.

The patient, then, has described a dream which we have to interpret. We have listened quietly without making use of our powers of

reflection. What do we do next? We determine to bother our heads as little as possible over what we have heard—over the *manifest* dream, that is to say. Naturally this manifest dream displays all sorts of characteristics to which we are not completely indifferent. It may be coherent, smoothly composed, like a literary work, or unintelligibly confused, almost like a delirium; it may have absurd elements, or jokes and apparently brilliant inferences; it may seem clear and well defined to the dreamer, or it may be dim and indefinite; the pictures in it may have the full sensuous force of a perception, or they may be as shadowy and vague as a mist. The greatest variety of characteristics can be found distributed in the various parts of the same dream. Finally, the dream may be attended by an indifferent feeling tone, or by a very strong pleasurable or painful affect. You must not think that we regard this endless variety as a matter of no importance; we shall come back to it later, and shall find in it much that is useful for our interpretation; but for the present we must put it aside, and travel along the main road which leads to the interpretation of the dream. This means that we ask the dreamer as well to free himself from the impression of the manifest dream, to switch his attention from the dream as a whole to individual parts of its content, and to tell us one after another the things that occur to him in connection with these parts, what associations come into his mind when he turns his mental eye on to each of them separately.

That is a curious technique, is it not? It is not the usual way to treat a communication or an utterance. You guess, of course, that behind this procedure there lie concealed assumptions which have not yet been mentioned. But let us proceed. In what order shall we get the patient to take the parts of his dream? Here we have a variety of courses open to us. We can simply follow the chronological order in which the dream has been presented to us in description. That is what one might call the strictest, the classical method. Or we can ask the dreamer to look for the *residue of the previous day* in his dream, because experience has taught us that in almost every dream is incorporated a memory trace of, or an allusion to, an event (or it may be several events) of the previous day; and if we follow up these links we often discover all of a sudden the bridge from the apparently remote dream-world to the real life of the patient. Or else we tell him to begin with those elements in the dream-content which have

struck him on account of their clarity and sensuous force. We happen to know that it is particularly easy for him to obtain associations to such elements. It makes no difference by which of these ways we choose to reach the associations we are looking for.

And now let us consider these associations. They consist of the most varied material, memories of the day before, the "dream day," and memories of times long since passed, deliberations, arguments for and against, admissions and questionings. A great many of them are poured out by the patient with ease, while he hesitates when he reaches others. Most of them show a clear connection with one of the elements of the dream, and no wonder, because they have actually sprung from these elements; but it may also happen that the patient introduces them with the words: "That doesn't seem to have anything to do with the dream at all; I say it because it comes into my head."

When one listens to this flood of ideas, one soon notices that they have more in common with the content of the dream than the mere fact that it provided them with their origin. They throw an astonishingly clear light on all the parts of the dream, they fill in the gaps between them, and they make their odd juxtaposition intelligible. Finally, we must get clear the relation between them and the content of the dream. The dream seems to be an abridged extract from the associations, which has been put together in accordance with rules which we have not yet considered; its elements are like the representatives of a multitude which have been chosen by vote. There is no doubt that our technique has enabled us to discover what the dream has replaced, and wherein lies its psychological value; and what we have discovered displays no longer the bewildering peculiarities of the dream, its strangeness and its confused nature.

But let us have no misunderstanding. The associations to the dream are not the latent dream-thoughts. These are contained, but not completely contained, in the associations. On the one hand, the associations produce a great deal more than we require for the formulation of the latent dream-thoughts, namely, all the elaborations, the transitions, and the connecting links, which the intellect of the patient must produce on the road which leads to the dream-thoughts. On the other hand, the association has often stopped short immediately before it has reached the dream-thoughts themselves; it has only touched them allusively. We

now play a part ourselves: we follow up the indications, we draw inevitable conclusions and bring out into the open what the patient in his associations has only touched upon. That sounds as if we allow our cleverness and our arbitrary imagination to play with the material which the dreamer has placed at our disposal, and misuse it to the extent of reading into his utterances what we have no business to find there; and indeed it is no easy matter to show the propriety of our behaviour in an abstract exposition. But if you try a dream-analysis yourselves, or make yourselves familiar with a well-described example from our literature, you will be convinced of the compelling manner in which such a process of interpretation unfolds itself.

Although in dream-interpretation we are in general and predominantly dependent on the associations of the dreamer, nevertheless we treat certain elements of the content quite independently—mainly because we have to, because, as a rule, associations refuse to come. We noticed at an early stage that this happens always in connection with the same material; these elements are not very numerous, and long experience has taught us that they are to be taken as *symbols* for something else, and to be interpreted as such. In comparison with the other elements of the dream, one can give them a permanent meaning, which need not, however, be ambiguous, and the limits of which are determined by special laws, which are of an unusual kind. Since we understand how to translate these symbols, while the dreamer does not, although he himself has made use of them, it may very well be that the sense of the dream is immediately clear to us, even before we have begun the work of dream-interpretation, as soon as we have heard the text of the dream, while the dreamer himself is still puzzled by it. But in the earlier lectures I have already said so much about symbolism, about our knowledge of it, and about the special problems to which it gives rise, that I need not go over the same ground again today.

That, then, is our method of dream-interpretation. The next and very proper question is: Can we by these means interpret every dream? And the answer is: No, not every one; but so many that we can afford to be absolutely certain about the utility and correctness of our procedure. But why not all? The recent answer to this question will teach us something important, which has a bearing on the psychological conditions of dream formation. It is because the work of interpretation is carried on

in the face of resistance, which may vary from an imperceptible amount to an amount so great that we cannot overcome it—at any rate with the means which are at present at our disposal. One cannot help observing the manifestation of this resistance during the interpretation. In many places the associations are given without hesitation, and the first or second of them already provides us with the explanation. In other places the patient pauses and hesitates before he utters an association, and then one often has to listen to a long chain of ideas before one gets anything which is of any use for the understanding of the dream. We are right in supposing that the longer and the more circuitous the chain of associations, the stronger is the resistance. And in the forgetting of dreams, too, we sense the same influence. Often enough it happens that, however much he may try, the patient cannot remember one of his dreams. But when, by a piece of analytical work, we have removed a difficulty which has been disturbing the patient in his relation to the analysis, the forgotten dream will come into his mind quite suddenly. Two more observations may be mentioned here. It very often happens that a piece of the dream is missing, which is eventually added as an afterthought. This is to be regarded as an attempt to forget that particular piece. Experience shows that it is this very piece of the dream which is the most valuable; we suppose that a stronger resistance stood in the way of its communication than was the case with the other parts. And, furthermore, we often find that a patient may try to combat the forgetting of his dreams by writing them down immediately after he wakes up. We may as well tell him that it is useless to do so, because the resistance from which he may have preserved the text of the dream will then transfer itself to the associations and render the manifest dream inaccessible for interpretation. This being the case, we need not be surprised if a further increase of the resistance suppresses the associations altogether, and thus frustrates the interpretation of the dream entirely.

From all this we draw the conclusion that the resistance which we come across during the process of dream-interpretation must play some part in the formation of the dream as well. One can actually distinguish between dreams which have been formed under low pressure of resistance and those in which the resistance has been high. But this pressure also changes within the same dream from one place

to another; it is responsible for the gaps, the obscurities and the confusion which may upset the coherence of the most beautiful dreams.

But what is the resistance doing here, and what is it resisting? Now for us a resistance is the sure sign of a conflict. There must be a force present which is trying to express something, and another which is striving to prevent its expression. What comes into being as the manifest dream may, therefore, be regarded as comprising all the solutions to which the battle between these two opposing forces can be reduced. At one point one of the forces may have been able to get through what it wanted to say, at another the counteracting force may have succeeded in abolishing the intended communication entirely, or may have substituted for it something which betrays no sign of it. The most usual cases, and those which are the most characteristic of the process of dream-formation, are those in which the conflict results in a compromise, so that the communicating force can indeed say what it wants to say, but not in the way it wants to say it; it is toned down, distorted, and made unrecognizable. If, therefore, the dream does not faithfully represent the dream-thoughts, if a process of interpretation is necessary to bridge the gulf between the two, this is the result of the counteracting, inhibiting, and restraining force whose existence we have inferred from perceiving the resistance in dream-interpretation. So long as we regarded the dream as an isolated phenomenon, independent of other psychological formations which are allied to it, we called this force the *dream-censor*.

You have long been familiar with the fact that this censorship is not a mechanism which is peculiar to dreams. You remember that the conflict of two psychic factors, which we—roughly—call the *repressed unconscious* and the *conscious*, dominates our lives, and that the resistance against the interpretation of dreams, the hall-mark of the dream-censorship, is none other than the repression-resistance which keeps these two factors apart. You also know that, under certain conditions, other psychological formations emerge from the conflict between these same factors, formations which are the result of compromises just as dreams are; and you will not require me to repeat all that is involved in my introduction to the theory of the neuroses in order to put before you what we know about the conditions under which such compromise formations come about. You will have realized that the dream is a pathological

product, the first member of the series which includes the hysterical symptom, the obsession, and the delusion among its members; it is differentiated from the others by its transitoriness and by the fact that it occurs under conditions which are part of normal life. For we must never forget that the dream-life is, as Aristotle has already told us, the way our mind works during sleep. The state of sleep represents a turning away from the real external world, and thus provides a necessary condition for the development of a psychosis. The most penetrating study of serious cases of psychosis will reveal no characteristic which is more typical of these pathological conditions. In psychoses, however, the turning away from reality is brought about in two ways; either because the repressed unconscious is too strong, so that it overwhelms the conscious, which tries to cling on to reality, or because reality has become so unbearably painful that the threatened ego, in a despairing gesture of opposition, throws itself into the arms of the unconscious impulses. The harmless dream-psychosis is the result of a consciously willed, and only temporary, withdrawal from the external world; it ceases to operate when relations with the external world are resumed. While the sleeper is isolated, there is an alteration in the distribution of his psychic energy; part of the repressive expenditure, which is otherwise used to keep down the unconscious, can be saved, for if the unconscious makes use of its relative freedom and enters on some activity, it finds the avenue to motor expression stopped up, and only the innocent outlet of hallucinatory satisfaction open to it. It can now, therefore, form a dream, but the fact of dream-censorship shows that enough repressive resistance remains operative even during sleep.

Here we have an opportunity of answering the question whether the dream has also a function to perform, whether any useful task is entrusted to it. The condition of repose without stimuli, which the state of sleep attempts to bring about, is threatened from three sides: in a chance fashion by external stimuli during sleep, by interests of the day-before which have not yet abated, and, in an unavoidable manner, by the unsatisfied repressed impulses, which are ready to seize on any opportunity for expression. On account of the nightly reduction of the repressive forces, the risk is run that the repose of sleep will be broken every time the outer and inner disturbances manage to link up with one of the unconscious sources

of energy. The dream-process allows the result of such a combination to discharge itself through the channel of a harmless hallucinatory experience, and thus insures the continuity of sleep. There is no contradiction of this function in the fact that the dream sometimes wakes the sleeper in a state of anxiety; it is rather a sign that the watcher regards the situation as being too dangerous, and no longer thinks he can cope with it. Quite often, indeed, while we are still asleep, we are aware of the comforting thought, which is there to prevent our waking up: "After all, it is only a dream."

That is all, ladies and gentlemen, that I wanted to say about dream-interpretation, the business of which is to trace the manifest dream back to the latent dream-thoughts. When this has been done, the interest in the dream from the point of view of practical analysis fades. The analyst links up the communication which he has received in the form of a dream with the patient's other communications and proceeds with the analysis. We, however, wish to linger a little longer over the dream; we are tempted to study the process by means of which the latent dream-thoughts are transformed into the manifest dream. We call this the *dream-work*. You will remember that in the previous lectures I described it in such detail that, for today's review of the subject, I can confine myself to the briefest summary.

The process of dream-work is something quite new and strange, the like of which has never before been known. It has given us our first glimpse into those processes which go on in our unconscious mental system, and shows us that they are quite different from what we know about our conscious thought, and that to this latter they must necessarily appear faulty and preposterous. The importance of this discovery is increased when we realize that the same mechanisms—we hardly dare call them "thought processes"—are at work in the formation of neurotic symptoms as have turned the latent dream-thoughts into the manifest dream.

In what follows, I cannot avoid making my exposition a schematic one. Supposing we have before us in a given instance all the latent thoughts, more or less affectively toned, which have taken the place of the manifest dream after a complete interpretation. We shall then notice a distinction among them, and this distinction will take us a long way. Almost all these dream-thoughts will be recognized or acknowledged by the dreamer; he will admit that he thought thus at one time or another, or that

he might very well have done so. But he may resist the acceptation of one single thought, it is foreign to him, perhaps even repellent; it may be that he will passionately repudiate it. Now it becomes clear to us that the other thoughts are bits of his conscious, or, more correctly, of his pre-conscious thought; they might very well have been thought during waking life, and have probably formed themselves during the day. This one rejected thought, or, better, this one impulse, is a child of the night; it belongs to the unconscious of the dreamer, and is therefore disowned and repudiated by him. It had to await the nightly relaxation of repression in order to achieve any sort of expression. In any case, the expression that it obtains is enfeebled, distorted, and disguised; without the work of interpretation we should never have discovered it. It is thanks to its connection with the other unobjectionable dream-thoughts that this unconscious impulse has had the opportunity of slipping past the barrier of the censorship in an unostentatious disguise; on the other hand, the pre-conscious dream-thoughts owe to the same connection their power of occupying the mental life, even during sleep. We can, indeed, have no doubt about this: the unconscious impulse is the real creator of the dream, it provides the psychic energy required for its formation. Just like any other instinctual impulse it can do no other than seek its own satisfaction, and our experience in dream-interpretation shows us, moreover, that this is the meaning of all dreaming. In every dream an instinctual wish is displayed as fulfilled. The nightly cutting-off of mental life from reality, and the regression to primitive mechanisms which it makes possible, enable this desired instinctual satisfaction to be experienced in a hallucinatory fashion as actually happening. On account of the same process of regression, ideas are turned into visual pictures in the dream; the latent dream-thoughts are, that is to say, dramatized and illustrated.

From this piece of dream-work we obtain information about some of the most striking and peculiar characteristics of the dream. Let me repeat the stages of dream-formation. The introduction: the wish to sleep, the voluntary withdrawal from the outside world. Two things follow from this: firstly, the possibility for older and more primitive modes of activity to manifest themselves, i.e., regression; and, secondly, the decrease of the repression-resistance which weighs on the unconscious. As a result of this latter feature, an opportunity for dream-

formation presents itself, which is seized upon by the factors which are the occasion of the dream; that is to say, the internal and external stimuli which are in activity. The dream which thus eventuates is already a compromise-formation; it has a double function: it is on the one hand in conformity with the ego (*ego-syntonic*), since it subserves the wish to sleep by draining off the stimuli which would otherwise disturb it, while on the other hand it allows to a repressed impulse the satisfaction which is possible in these circumstances in the form of an hallucinatory wish-fulfilment. The whole process of dream-formation, which is permitted by the sleeping ego, is, however, under the control of the censorship, a control which is exercised by what is left of the forces of repression. I cannot explain the process more simply; it is not in itself simpler than that. But now I can proceed with the description of the dream-work.

Let us go back once more to the latent dream-thoughts. Their dominating element is the repressed impulse, which has obtained some kind of expression, toned down and disguised though it may be, by associating itself with stimuli which happen to be there and by tacking itself on the residue of the day before. Just like any other impulse this one presses forward toward satisfaction in action, but the path to motor discharge is closed to it on account of the physiological characteristics of the state of sleep, and so it is forced to travel in the retrograde direction to perception, and content itself with an hallucinatory satisfaction. The latent dream-thoughts are therefore turned into a collection of sensory images and visual scenes. As they are travelling in this direction something happens to them which seems to us new and bewildering. All the verbal apparatus by means of which the more subtle thought-relations are expressed, the conjunctions and prepositions, the variations of declension and conjugation, are lacking, because the means of portraying them are absent: just as in primitive, grammarless speech, only the raw material of thought can be expressed, and the abstract is merged again in the concrete from which it sprang. What is left over may very well seem to lack coherence. It is as much the result of the archaic regression in the mental apparatus as of the demands of the censorship that so much use is made of the representation of certain objects and processes by means of symbols which have become strange to conscious thought. But of more far-reaching import are

the other alterations to which the elements comprising the dream-thoughts are subjected. Such of them as have any point of contact are *condensed* into new unities. When the thoughts are translated into pictures, those forms are indubitably preferred which allow of this kind of telescoping, or condensation; it is as though a force were at work which subjected the material to a process of pressure or squeezing together. As a result of condensation, one element in a manifest dream may correspond to a number of elements of the dream-thoughts; but, conversely, one of the elements from among the dream-thoughts may be represented by a number of pictures in the dream.

Even more remarkable is the other process of *displacement* or transference of accent, which in conscious thinking figures only as an error in thought or as a method employed in jokes. For the individual ideas which make up the dream-thoughts are not all of equal value; they have various degrees of affective-tone attached to them, and corresponding to these, they are judged as more or less important, and more or less worthy of attention. In the dream-work these ideas are separated from their affects; the affects are treated separately. They may be transferred to something else, they may remain where they were, they may undergo transformation, or they may disappear from the dream entirely. The importance of the ideas which have been shorn of their affect reappears in the dream in the form of the sensuous vividness of the dream-pictures; but we notice that this accent, which should lie on important elements, has been transferred to unimportant ones, so that what seems to be pushed to the forefront in the dream, as the most important element in it, only plays a subsidiary rôle in the dream-thoughts, and, conversely, what is important among the dream-thoughts obtains only incidental and rather indistinct representation in the dream. No other factor in the dream-work plays such an important part in rendering the dream strange and unintelligible to the dreamer. Displacement is the chief method employed in the process of *dream-distortion*, which the dream-thoughts have to undergo under the influence of the censorship.

After these operations on the dream-thoughts, the dream is almost ready. There is still, however, a more or less non-constant factor, the so-called *secondary elaboration*, that makes its appearance after the dream has come into consciousness as an object of perception. When the dream has come into consciousness, we

treat it in exactly the same way that we treat any content of perception; we try to fill in the gaps, we add connecting links, and often enough we let ourselves in for serious misunderstandings. But this, as it were, rationalizing activity, which at its best provides the dream with a smooth façade, such as cannot correspond to its real content, may be altogether absent in some cases, or only operate in a very feeble way, in which case the dream displays to view all its gaps and inconsistencies. On the other hand, one must not forget that the dream-work, too, does not always function with equal force; quite often it limits its activity to certain parts of the dream-thoughts, while others are allowed to come into the dream unaltered. In this event, one has the impression that one has carried out the most complicated and subtle intellectual operations during the dream, that one has made brilliant speculations or jokes, or that one has come to decisions or solved problems; really, however, all this is the result of our normal mental activity, and may just as well have happened during the day before the dream as during the night. It has nothing to do with the dream-work, nor does it display any feature which is characteristic of dreams. It is perhaps not superfluous once more to emphasise the distinction which subsists among the dream-thoughts themselves, between the unconscious impulse and the residues of the preceding day. While the latter exhibit the whole variety of our mental activity, the former, which is the real motive force of the dream, always finds its outlet in a wish-fulfilment.

I could have told you all that fifteen years ago; in fact I actually did tell it you at the time. Now let us bring together such modifications and new discoveries as have been made during the interval.

I have already told you that I am afraid you will find that there is very little to say; so you will not understand why I have obliged you to listen to the same thing twice over, and have obliged myself to say it. But fifteen years have passed, and I hoped that in this way I might most easily re-establish contact with you. And indeed these elementary matters are of such decisive importance for the understanding of psycho-analysis that it is a good thing to hear them for a second time, and the very fact that they have remained the same after fifteen years is in itself something worth knowing.

You will naturally find in the literature of these years a great deal of confirmatory material and exposition of details, of which I only

intend to give you examples. I can also add to this a certain amount that was already known before. Most of it has to do with symbolism and the other methods of representation in dreams. Only quite recently the physicians at an American university refused to allow that psycho-analysis was a science, on the ground that it admits of no experimental proof. They might have raised the same objection against astronomy; experimentation with the heavenly bodies is, after all, exceedingly difficult. There one has to rely on observation. Nevertheless, certain Viennese investigators have made a start on the experimental confirmation of our theory of dream-symbolism. Dr. Schrötter discovered as long ago as 1912 that when one orders a deeply hypnotized person to dream of sexual activities, the sexual material in the dream that is thus provoked is represented by the symbols which are familiar to us. For example, a woman is told to dream of sexual intercourse with a lady friend of hers. In her dream the friend appears with a travelling-bag, which has a label pasted on it: "Ladies only." Even more impressive are the experiments of Betlheim and Hartmann (1924), who worked with patients suffering from the so-called Korsakow's syndrome. They told the patient stories with a crude sexual content, and then noted the distortions which appeared when he was asked to reproduce what he had heard. Here again the symbols with which we are familiar as standing for the sexual organs and sexual intercourse cropped up, and among them the symbol of a staircase, with regard to which the authors very properly observe that it would be inaccessible to a conscious intention to distort.

Silberer performed a very interesting series of experiments in which he showed that one can surprise the dream-work, as it were, *in flagrante delicto*, and see how it translates the abstract thoughts into visual pictures. When he tried to force himself, in a very tired and sleepy condition, to perform an intellectual task, the thought itself would escape him, and in its place would come a visual image, which was often a substitute for it.

Here is a simple example. The thought which Silberer set before himself was that he must smooth out an uneven passage in an article. His visual image was that he saw himself planning a piece of wood. It often happened in these experiments that it was not the idea which was awaiting elaboration that formed the content of the visual image, but his own state of mind

while he was trying to make the effort—the subjective condition rather than the objective content. This Silberer calls a *functional phenomenon*. An example will easily show you what is meant. The author is trying to make a comparison between the views of two philosophers about some problem, but in his drowsiness one of these views is always escaping him, and finally he has a vision of himself asking information of a cross-grained secretary, who is leaning over his desk and disregards him at first and then looks at him with a disagreeable expression, as if he would like to send him about his business. It is probably due to the conditions of the experiment itself that the visual images which are aroused in this way so often represent introspective material.

Let us consider symbols a little longer. There were some which we thought we had grasped, but about which we were nevertheless troubled because we could give no account of how that particular symbol got its particular meaning. In such cases any confirmation we could get from other sources, from philology, folklore, mythology or ritual, was particularly welcome. An example of this kind was the symbol of a cloak. We held that in a woman's dream a cloak stood for a man. I hope now you will be impressed when you hear that Reik (1920) tells us: "In the ancient marriage ceremony of the Bedouins, the bridegroom covers the bride with a special cloak which is called an 'aba,' and at the same time utters the ritual words: 'Let no man in the future cover thee but me'" (from Robert Eisler, *Weltenmantel und Himmelszelt*). We have also discovered a great many new symbols, of which I will give you two examples. According to Abraham (1922), a spider in a dream is a symbol of the mother; but it means the phallic mother, whom one fears, so that the fear of the spider expresses the horror of incest with the mother and the abhorrence felt towards the female genitals. You know, perhaps, that the mythological figure of the Medusa's head is to be traced back to the same motif of castration-fear. The other symbol of which I should like to speak is the symbol of the bridge. Ferenczi has explained it (1921-1922). It stands originally for the male genital organ, which connects the parents with each other during sexual intercourse; but it develops into a wider set of meanings, which spring out of the first. Since the male genital organ is responsible for the fact that one can emerge from the waters of birth into the world, the bridge depicts the passage from Yonder (not-yet-born-

ness, the womb) to Here (life), and since mankind also represents death as the return into the mother's womb (into the water), the symbol of the bridge gets the meaning of something that brings about death; and finally, further removed from its original meaning, it indicates transition, or any change of condition whatever. That is why a woman who has not yet overcome her desire to be a man so frequently dreams of bridges which are too short to reach the other side.

Very often pictures and situations appear in the manifest content of the dream which remind one of well-known themes from fairy stories, legends and myths. The interpretation of such dreams throws light on the original motives which created these themes, though naturally we must not forget the change of meaning which this material has undergone during the passage of time. Our work of interpretation uncovers what one might call the raw material, which often enough may be regarded as sexual in the broadest sense of the word, but which has found the most varied application in later elaborations. When we trace things back like this, we very often arouse the rage of all investigators who do not share the analytical point of view, as though we were seeking to deny or underestimate all the later developments which the raw material has undergone. None the less, such ways of looking at things are instructive and interesting. The same is true of the tracing back of various motifs of plastic art—as, for example, when J. Eisler (1919), guided by the dreams of his patients, interprets analytically the young man playing with a little boy, portrayed in the *Hermes* of Praxiteles. Finally, I cannot help mentioning how often mythological themes find their explanation through dream-interpretation. The story of the Labyrinth, for example, is found to be a representation of anal birth; the tortuous paths are the bowels, and the thread of Ariadne is the umbilical cord.

The method of representation which the dream-work adopts, a fascinating and almost inexhaustible subject, is constantly becoming better known to us as we study it more closely. I will give you a few proofs of this. The notion of frequency, for instance, is expressed in dreams by means of the multiplication of similars. Listen to this remarkable dream of a young girl. She goes into a hall and finds there a person sitting on a chair; this figure is repeated six times, eight times, and even more, but every time the person is her father. This

can easily be understood when one learns from the additional features which emerged in interpretation that the room represents the womb. The dream then becomes equivalent to the familiar fantasy of the young girl who believes that she met her father during her intra-uterine life, when he visited the womb during her mother's pregnancy. The fact that an element in the dream is turned the wrong way round, that the act of entry is transferred from the father to the dreamer herself, should not lead you astray; it has indeed a special meaning of its own. The multiplication of the father image can only mean that the procedure in question was frequently repeated. But then the dream always turns temporal relations into spatial ones whenever it has to deal with them. Thus, one may see in a dream a scene between people who look very small and far away, as if one were looking at them through the wrong end of a pair of opera glasses. The smallness and the spatial remoteness here mean the same; it is remoteness in time that is meant, the interpretation being that it is a scene from the far distant past. Besides this, you may remember that in my previous lectures I showed you, with the help of examples, that we had learnt to make use even of the purely formal characteristics of the manifest dream for purposes of interpretation; that is to say, to turn them into the content of the latent dream-thoughts. Now you know, of course, that all the dreams of one night belong to the same context; but it is by no means immaterial whether these dreams appear to the dreamer as a continuum, or whether they are organized in several pieces, and if so in how many. The number of pieces often corresponds to the same number of distinct nodal points in the chain of thoughts, which make up the latent dream-thoughts; or it may correspond to forces in the mental life of the dreamer which are struggling with one another, and each of which finds its main (though not its exclusive) expression in one particular part of the dream. A short introductory dream and a long main dream often stand to each other in the relation of condition and consequence; of this you will find a very clear example in the old lectures. A dream which the dreamer describes as "somehow interpolated" really corresponds to a dependent clause in the dream-thoughts. Franz Alexander in his essay on pairs of dreams that not infrequently two dreams which occur on the same night play separate parts in the fulfilment of the dream-function, so that taken together they

provide a wish-fulfilment in two steps, a thing which each alone does not do. If a dream-wish has as its content some piece of forbidden behaviour towards a certain individual, then that person may appear in the first dream undisguised while the behaviour is only faintly indicated. In the second dream it will be the other way round. The behaviour will be openly shown, but the person will be made unrecognizable, or else some indifferent person will be substituted for him. It must be admitted that this gives one an impression of deliberate artfulness. A second and similar relation between two members of a pair of dreams is that in which the one represents the punishment and the other the sinful wish-fulfilment. It is just as if one said: "If I take the punishment on myself, then I can do the forbidden thing."

I must not detain you longer with such discoveries of matters of detail, nor with discussions of the uses of dream-interpretation in analytic work. I am sure you are impatient to hear what alterations have been made in our basic attitude towards the nature and meaning of dreams. You will be prepared to hear that there is little to tell. The most hotly disputed point of the whole theory was undoubtedly the assertion that all dreams are wish-fulfilments. The inevitable and ever-recurrent objection from the laity that there are so many anxiety-dreams has already been completely answered, I think, in my earlier lectures. We have kept our theory intact by dividing dreams into wish-dreams, anxiety-dreams, and punishment-dreams.

Even punishment-dreams are wish-fulfilments, but they do not fulfil the wishes of the instinctual impulses, but those of the critical, censoring, and punishing function of the mind. If we are faced with a pure punishment-dream, a simple mental operation will enable us to reinstate the wish-dream to which the punishment-dream was the proper rejoinder; on account of this repudiation, the punishment-dream has appeared in place of the wish-dream as the manifest one. You know, ladies and gentlemen, that the study of dreams was the first thing that helped us to understand the neuroses. And you will not be surprised to hear that our subsequent knowledge of the neuroses has influenced our conception of the dream. As you will learn presently, we have been forced to assume the existence in the mind of a special criticizing and forbidding function which we call the *super-ego*. Since we have now recognized the dream-censorship as an activity of this

function, we have been led to consider the part which the super-ego plays in dream-formation in greater detail.

Only two serious difficulties face the wish-fulfilment theory of dreams, the examination of which leads us far afield and for which we have found no completely satisfactory solution. The first difficulty is presented by the fact that people who have had severe shocks or who have gone through serious psychic traumas (such as were frequent during the war, and are also found to lie at the back of traumatic hysteria) are continually being put back into the traumatic situation in dreams. According to our acceptance of the function of dreams, this ought not to be the case. What conative impulse could possibly be satisfied by this reinstatement of a most painful traumatic experience? It is indeed hard to guess. We meet with the second fact almost daily in our analytical work; it does not involve such a serious objection as the other. You know that it is one of the tasks of psycho-analysis to lift the veil of amnesia which shrouds the earliest years of childhood and to bring the expressions of infantile sexual life which are hidden behind it into conscious memory. Now these first sexual experiences of the child are bound up with painful impressions of anxiety, prohibition, disappointment, and punishment. One can understand why they have been repressed; but, if so, it is difficult to see why they should have such easy access to dream-life, why they should provide the pattern for so many dream-phantasies, and why dreams are full of reproductions of these infantile scenes and allusions to them. The pain that attaches to them and the wish-fulfilling tendency of the dream-work would seem to be incompatible. But perhaps in this case we exaggerate the difficulty. All the imperishable and unrealizable desires which provide the energy for the formation of dreams throughout one's whole life are bound up with these same childish experiences, and one can well trust to their ability with their powerful upward thrust to force even material of a painful nature to the surface. And, on the other hand, in the manner in which this material is reproduced the efforts of the dream-work are unmistakable; it disowns pain by means of distortion and turns disappointment into fulfilment. In the case of the traumatic neuroses it is quite different; here the dream habitually ends in anxiety. In my opinion we ought not to shirk the admission that in such cases the function of the dream fails. I will not have

recourse to the saying that the exception proves the rule; the validity of this phrase seems to me very dubious. But at any rate the exception does not do away with the rule. If for the purposes of investigation one isolates from every other mental process a single psychic activity like the dream, one is enabled to discover the laws which govern it; if one then puts it back into its place, one must be prepared to find that one's discoveries are obscured and interfered with when they come into contact with other forces. We assert that the dream is a wish-fulfilment; in order to take these last objections into account, you may say that the dream is an *attempted* wish-fulfilment. But for those who have an understanding for the dynamics of the mind you will not be saying anything different. Under certain conditions the dream can only achieve its end in a very incomplete way, or has to abandon it entirely; an unconscious fixation to the trauma seems to head the list of these obstacles to the dream-function. The sleeper has to dream, because the nightly relaxation of repression allows the upward thrust of the traumatic fixation to become active; but sometimes his dream-work, which endeavours to change the memory traces of the traumatic event into a wish-fulfilment, fails to operate. In these circumstances, the result is that one becomes sleepless; one gives up all idea of sleep because of one's fear of the failure of the dream-function. The traumatic neurosis is an extreme case, but one must also attribute a traumatic character to infantile experiences as well; so one need not be surprised if lesser disturbances of the function of the dream occur in other circumstances.

### LECTURE 30

#### DREAMS AND THE OCCULT

LADIES AND GENTLEMEN: Today we are to travel along a narrow path, but it may lead us to a wide prospect.

When you hear that I am going to talk about the connection between dreams and the occult, you need hardly feel surprised. Dreams are indeed often regarded as the portal to the world of mysticism, and even today seem to many to be in themselves an occult phenomenon. Even we, who have made them an object of scientific study, cannot deny that several strands link them up with those obscure regions. Mysticism—occultism—what is meant by these terms? Do not imagine that I shall attempt to provide you with a clear definition of such hazy con-

cepts. In a general and vague way we all know what we mean by the terms. They refer to a kind of "other world" which lies beyond the clear world, with its inexorable laws, which science has built up for us.

Occultism assumes that there are in fact more things in heaven and earth than are dreamt of in our philosophy. Well, we need not be tied down by the narrow-mindedness of the Schools; we are ready to believe whatever is made plausible to us.

We intend to treat these things in just the same way as we treat any other material for scientific investigation. First, we have to establish whether these processes really occur, and then, but only then, when there is no doubt as to their actuality, we can set about their explanation. But we cannot hide from ourselves the fact that even the first step will be made difficult for us by intellectual, psychological, and historical factors. It is by no means the same as when we start on any other investigation.

Let us consider the intellectual difficulties first. Allow me to give you a crude, obvious explanation of what I mean. Supposing we are dealing with the constitution of the interior of the earth. Admittedly we know nothing certain about it. We suppose that it consists of heavy metals in a molten condition. Now let us imagine that some one asserts that the interior of the earth is made of water impregnated with carbonic acid; that is to say, a kind of soda-water. We shall certainly say that it is very improbable, that it runs counter to all our expectations, and that it does not take into consideration the scientific data which have led us to put forward the mental hypothesis. But for all that it is not unthinkable. If any one shows us the way to prove the soda-water hypothesis, we shall follow it without any resistance. But now another person comes along who seriously asserts that the centre of the earth is made of jam. We shall behave quite differently towards his theory. We shall say to ourselves that jam is not a product of Nature but of human cookery; moreover, the existence of that material presupposes the presence of fruit-trees and their fruit, and we cannot see our way to placing vegetation and human cookery in the centre of the earth. The result of this intellectual objection will be a diversion of our interests; instead of their being directed on to the investigation itself, as to whether the interior of the earth is really made of jam or not, we shall wonder what kind of man it must

be who can get such an idea into his head, or at the most we shall ask him where he got the idea from. The unfortunate inventor of the jam hypothesis will be very much offended, and will complain that we are refusing to consider an objective evaluation of this theory out of what he calls scientific prejudice. But his complaints will be in vain. Prejudices, we feel, are not always to be deplored, but are sometimes justified; and they are useful in saving us unnecessary trouble. They are, indeed, nothing more than conclusions drawn by analogy from other well-founded judgments.

A whole number of occult theories make the same impression on us as the jam theory, so that we feel justified in putting them aside at the outset without testing them. But it is not quite such a simple matter. An analogy such as I have suggested—like all analogies—proves nothing. In any case it is doubtful whether it is a fair analogy, and it is obvious that it was our attitude of scornful rejection which in the first instance determined our choice of it. Prejudices are very often useful and justified, but sometimes they are erroneous and harmful, and one never knows when they will be the one or the other. The history of science is full of examples which should warn us against too hasty a condemnation. For a long time it was thought to be an absurd thesis that the stones which we now call meteorites should have reached the earth from outer space, or that mountains, the rocks of which contain remains of shells, should once have formed the bed of the sea. And, after all, not so very different a fate befell our psycho-analysis itself, when it brought forward the discovery of the unconscious. We analysts, therefore, have special reason to be cautious in making use of intellectual arguments in the rejection of new theories, and we must recognize that such arguments will not put us beyond the reach of feelings of aversion, doubt, and uncertainty.

I called the second factor psychological. By that I meant the general human inclination towards credulity and belief in the marvellous. From the very beginning, when life imposes its stern discipline upon us, there grows up in us a resistance against the restlessness and monotony of the laws of thought, and against the need for putting things to the test of reality. Reason becomes an enemy that keeps us from so many possibilities of pleasure. One discovers what a joy it is to escape from it at least for a moment, and give oneself up to the fascination of irrationality. The schoolboy amuses himself

by making up ridiculous plays on words, the specialist makes fun of his own work after a scientific congress, and even the serious-minded man enjoys an occasional joke. More serious antagonism against "Wisdom and Science, man's most prized powers," awaits its opportunity; it is eager to prefer the miracle-man or the natural healer to the *trained* doctor, it makes us warm towards the theories of the occult, so long as its reputed facts can be taken as breaches of law and rule. It puts our critical faculty to sleep, falsifies our perception, and forces us to confirm and agree without real justification. Any one who takes these human weaknesses into consideration has every reason to discount the value of much of the information contained in occult literature.

In referring to the third obstacle as the historical one I had in mind the fact that nothing new is to be found in the world of the occult. On the contrary, we meet again in it with all the signs, wonders, prophecies, and apparitions which have been handed down to us from remote ages and in old books, and which we long ago thought we had done with as being the offspring of unbridled imagination or tendentious fraud, the product of a time when the ignorance of mankind was at its height and when the scientific spirit was still in its infancy. If we accept as true what we are told by the occultists of our own day, then we must be prepared to believe the accounts which have come down to us from the past. And then we remember that the traditions and sacred books of all races are packed with such marvels, and that religions base their claim to credibility precisely on such extraordinary and wondrous happenings, and find in them the proof of the operation of superhuman forces. At this point it is hard for us to avoid the suspicion that occult interests are really religious ones, and that it is one of the secret motives of the occultist movements to come to the aid of religious belief, threatened as it is by the progress of scientific thought. The discovery of a motive of this kind cannot fail to increase our mistrust and our disinclination to embark upon an investigation of these so-called occult phenomena.

But this disinclination must be overcome. The whole thing is really a question of fact: is what the occultists tell us true or not? It must be possible to decide this by observation. *Au fond*, we ought to be grateful to the occultists. The tales of wonderful happenings which have come down to us from ancient days are beyond our powers of testing. If we say that they can-

not be proved, we must at least admit that, strictly speaking, they cannot be disproved. But about what happens in the present, about things which we can actually witness, we ought to be able to reach a definite conclusion. If we are convinced that such wonders do not occur nowadays, we need not fear the objection that they might have occurred in days gone by. Other explanations will then be far more plausible. We have, then, put aside our scruples and are ready to take part in the observation of occult phenomena.

Unfortunately, we come up against considerations which are highly unfavourable to our laudable intentions. The observations on which our judgments must depend have to be made under conditions which render our powers of perception insecure, and which blunt our faculty of attention; the phenomena take place in the dark or in the faint glimmer of a red light after long periods of fruitless waiting. We are told that even our sceptical—that is to say, our critical—attitude may very well prevent the hoped for phenomena from manifesting themselves. The situation which thus arises is simply a caricature of the conditions under which we are used to carrying out scientific investigations. The observations are made on so-called mediums, persons to whom are ascribed special “sensitive” gifts, who, however, do not display outstanding qualities of intelligence or character, and who are not moved, as the old wonder-workers were, by some great idea or by some serious purpose. On the contrary, they are regarded as particularly untrustworthy even by the people who believe in their mysterious powers; most of them have already been unmasked as frauds, and we are tempted to expect that the same will happen with the rest as well. Their performances remind us of the mischievous pranks of a child or of a conjuror’s tricks. Nothing of any value has so far ever come out of these *séances* with mediums; no new source of energy has become accessible to us. And, to be sure, one does not expect any advances in our knowledge of pigeon-breeding from the tricks of a conjuror who produces pigeons out of an empty top-hat. I can easily put myself into the position of a man who wishes to fulfil the demands of objectivity and therefore takes part in these occult *séances*, but tires of them after a while, and, put off by what is required of him, gives up the whole business and returns to his prejudices no wiser than before. To such a man one might object that his behaviour is not right, and that

if one is going to investigate phenomena one cannot decide beforehand of what nature they shall be and under what conditions they shall manifest themselves. It is, on the contrary, his business to persevere and form some estimate of the precautionary measures of control which are used nowadays as a protection against the untrustworthiness of mediums. Unfortunately, the modern control technique puts an end to the easy accessibility of occult observations. The study of the occult has become a specialized and difficult pursuit, a form of activity which one cannot carry on side by side with one’s other interests. And until the investigators who have given their minds to it have come to some conclusion, one is necessarily given over to doubts and to one’s own conjectures.

Among these conjectures the most probable is, I think, that in occultism there is a core of facts which have hitherto not been recognized, and round which fraud and phantasy have woven a veil which it is hard to penetrate. But how can we even approach this core? at what point can we grasp the problem? It is here, it seems to me, that the dream comes to our aid by suggesting to us that we should pick out the theme of telepathy from all the confused material that surrounds it.

You know that by *telepathy* we mean the alleged fact that an event which occurs at a specific time comes more or less simultaneously into the consciousness of a person who is spatially distant, without any of the known methods of communication coming into play. The tacit assumption is that this event occurs to a person, in whom the receiver of the message has some strong emotional interest. Thus, for example, a person A has an accident, or dies, and a person B, some one closely connected with A, his mother or daughter or loved one, learns of it at about the time of its occurrence through a visual or auditory perception; in the latter case it is as though they were in telephonic communication, which, however, they are not; in fact, it is a kind of psychic parallel to wireless telegraphy. I need not emphasize to you the improbability of such processes, and anyway there are good grounds for rejecting the majority of such reports. Some of them are left over which cannot be rejected so easily. I must now ask you to allow me to leave out the precautionary word *alleged* for the purposes of what I have to tell you, and to let me continue as though I believed in the objective reality of telepathic phenomena. But you must remember

all the time that this is not the case, that I have not committed myself to any conclusion on the subject.

As a matter of fact I have but little to tell you—only one modest fact. And I will further diminish your expectations by informing you that fundamentally the dream has but little to do with telepathy. Telepathy throws no new light on the nature of the dream, nor does the dream bear witness for the reality of telepathy. Telepathic phenomena are also by no manner of means confined to dreams; they can also manifest themselves during waking life. The only ground for mentioning the connection between dreams and telepathy is that the condition of sleep seems to be especially suitable for the reception of telepathic communications. If, then, one comes across a so-called *telepathic dream*, one can convince oneself by its analysis that the telepathic message has played the same rôle as any other residue of waking life, and as such has been altered by the dream-work and made to serve its purpose.

Now in the course of the analysis of a telepathic dream of this kind something occurred which seems to me of sufficient importance, in spite of its slightness, to serve as the starting-point for this lecture. When in the year 1922 I brought up this subject for the first time, I had only one observation at my disposal. Since then I have made several other observations; but I shall keep to the first example, because it is the easiest one to describe, and I shall proceed at once to the heart of the matter.

An obviously intelligent man, and one who according to his own estimation, was in no way "tainted with occultism" wrote to me about a dream which seemed to him to be remarkable. He prefaced his story with the information that his married daughter, who lived some distance from him, was expecting her first confinement in the middle of December. He was very much devoted to this daughter, and he knew that she was very much attached to him. Now he dreamed in the night between the 16th and 17th of November that his wife had had twins. There followed several details which I can pass over here, not all of which have found a satisfactory explanation. The woman who, in the dream, had become the mother of the twins, was his second wife, the daughter's step-mother. He did not wish to have children by this woman, whom he did not consider fitted for bringing up children in an understanding way, and at the time of the dream he had for a long time given up sexual

intercourse with her. What induced him to write to me was not a doubt about the validity of the theory of dreams, though the manifest dream would have justified him if that had been the case; for why does the dream, in flat contradiction to his wishes, depict this woman as bearing children? And according to his story he had no grounds for fearing that this unwished-for occurrence might take place. What determined him to tell me about his dream was the fact that early in the morning of November 18th he received a telegram to say that his daughter had given birth to twins. The telegram had been handed in the day before, and the birth had taken place during the night between the 16th and 17th, at about the same time that he had dreamt that his wife had had twins. The dreamer asked me whether I thought that the simultaneity of the dream and the event was a mere coincidence. He did not go so far as to call the dream a telepathic one, because the difference between the content of the dream and the event itself concerned precisely what he considered to be the most important point, the person who had the children. But from one of his remarks it looked as though he would not have been surprised if he had had a real telepathic dream. His daughter, he felt certain, had "thought especially about him" during labour.

Ladies and Gentlemen, I am sure that you can already explain the dream, and that you understand why I have told it to you. Here is a man, dissatisfied with his second wife, who would prefer to have a wife like his daughter by his first marriage. In the unconscious this *like* is naturally omitted. Now during the night he receives the telepathic communication that his daughter has had twins. The dream-work seizes on this information, allows his unconscious wish that his daughter should replace his second wife to act upon it, and thus emerges the singular manifest dream in which the wish itself is veiled and the message distorted. We must admit that only dream-interpretation has shown us that this is a telepathic dream; psycho-analysis has discovered a telepathic event which we should not otherwise have recognized as such.

But do not let yourselves be led astray. In spite of all this, dream-interpretation has said nothing about the objective truth of telepathic phenomena. It may be only an appearance which can be explained in some other way. It is possible that the man's latent dream-thoughts ran like this: "Today is the day on which the confinement must take place, if my daughter,

as I incidentally believe is the case, has been a month out in her calculations. And her appearance when I saw her last time was such that it looked as though she was going to have twins. And my dead wife was so fond of children: how delighted she would have been by twins!" (The last point is derived from associations of the dreamer which I have not yet mentioned.) In that case the stimulus for the dream would have been well-founded suspicions on the part of the dreamer and not a telepathic message; the result would have been the same in both cases. You notice that even this interpretation has told us nothing about the question of whether one should assign objective reality to telepathy. One could only come to a conclusion about that after making detailed enquiries into all the circumstances of the case, which unfortunately was impossible with this example, as it was with all the others in my experience. We may grant that the assumption of telepathy gives us by far the simplest explanation; but that does not carry us very far. The simplest explanation is not always the right one, truth is very often not simple, and one must act with the greatest caution before committing oneself to such a far-reaching assumption.

We can now leave the subject of dreams and telepathy; I have nothing more to say about it. But I want you to notice that it was not dreams that seemed to teach us something about telepathy, but the interpretation of the dreams, the psycho-analytic treatment of them. We can therefore leave dreams on one side in what follows, and we will examine further our suspicion that the application of psycho-analysis may throw a light on other so-called *occult facts*. There is, for example, the phenomenon of thought-transference, which is closely allied to telepathy and, indeed, can be identified with it without much difficulty. It is held that psychological processes, ideas, states of excitement, volitions, which occur in the mind of one person, can be transferred through space to another, without the usual means of communication (words or signs) being employed. Incidentally, it is remarkable that it is actually these phenomena which find the least mention in the old accounts of the miraculous.

During the psycho-analytic treatment of patients, I have had the impression that the activities of professional fortune-tellers provide an admirable opportunity for making really satisfactory observations of thought-transference. It is usually mediocre and even inferior

people who carry on practices of this sort, deal out cards, study writing and the lines upon the hand, or make astrological reckonings, and foretell the future of their visitors, after having shown some knowledge of their past or present history. Their clients usually express themselves as satisfied by their performances, and bear them no ill-will if their prophecies do not come true in the end. I have come across a great many such cases and have been able to study them analytically. I will tell you the most remarkable instances of the kind. Unfortunately the evidential value of this information is reduced on account of the numerous omissions which are necessitated by the rules of professional secrecy. I have, however, carefully avoided any distortions. This is the story of one of my female patients, who had an experience of the kind we are discussing with a fortune-teller.

She was the eldest of a family of brothers and sisters, grew up with an extraordinarily strong attachment to her father, had married young, and had found entire satisfaction in her married life. There was only one thing wanting to make her happiness complete; she was childless, and thus the husband whom she loved could not wholly fill the place of her father. When after many years she decided to have a gynaecological operation, her husband disclosed to her the fact that the fault lay in him, that through an illness which had occurred before marriage he had been rendered incapable of procreating children. She took this disappointment very badly, became neurotic, and suffered unmistakably from dread of the husband's attempts. In order to cheer her up, her husband took her with him on a business visit to Paris. While they were there, they were sitting one day in the hall of the hotel when she noticed a stir among the hotel servants. She asked what was happening, and learnt that Monsieur le Professeur had arrived and was giving consultations in a certain room. She expressed her wish to see what the thing was like herself. Her husband tried to dissuade her, but when he was not looking she slipped into the room where the fortune-teller was giving his consultations. She was twenty-seven years old, but looked much younger, and she had taken off her wedding-ring. Monsieur le Professeur told her to rest her hand on a bowl filled with ashes, carefully studied the imprint, and, after telling her all sorts of things about severe troubles which lay before her, concluded with the comforting assurance that she would get married all the same

and have two children by the time she was thirty-two years of age. When she told me this story she was forty-three, very ill, and with no expectation of ever having a child at all. The prophecy therefore had not come true, and yet she spoke of it with no bitterness whatever, but with an unmistakable expression of satisfaction, as though she were looking back with pleasure upon a happy experience. It was easy to assure oneself that she had not the slightest idea what the two numbers in the prophecy might mean, or whether they meant anything at all.

You will say that this is a stupid and incomprehensible story, and ask why I have related it to you. Now I should feel exactly as you do, but for the fact—and this is the important point—that the analysis enabled us to obtain an interpretation of the prophecy, which was actually most significant when it came to the details. For the two numbers have a place in the life of the *mother* of my patient. She had married late, when she was more than thirty, and her family had often remarked how successful she had been in making up for lost time. Her two first children—and our patient was the elder of these—had been born within a single calendar year with the smallest possible interval between them; and it was really true of her that by the time she was thirty-two she had two children. What Monsieur le Professeur told my patient meant this: "Cheer up, for you are still young! You will have the same experience as your mother, who also had to wait a long time for children, and you will have two children by the time you are thirty-two." But to have the same experience as her mother, to be in her position, to take her place with her father, was the strongest wish of her childhood, the wish whose non-fulfilment was beginning to make her ill. The prophecy promised her that it would be fulfilled, how could she feel otherwise than friendly towards the prophet? But do you think that Monsieur le Professeur could really have been familiar with the dates of the intimate family history of a chance client? It is impossible; whence, then, came the knowledge that enabled him to express in his prophecy the strongest and most secret wish of my patient by bringing in these two numbers? I can see only two possibilities. Either the story, as she told it to me, was not true and the events were different, or we must accept thought-transference as a real phenomena. It could, no doubt, be argued that my patient, after the lapse of sixteen years, had

carried over the two numbers we are discussing from her unconscious into her recollection. I have no evidence for this suggestion, but I cannot rule it out, and I imagine that you would prefer to believe in such an explanation rather than in the reality of thought-transference. If, however, you should accept the latter view, do not forget that it was only analysis that brought to light the occult element, which had been distorted out of all recognition.

If we had to deal with only *one* case like that of my patient, we should turn away from it with a shrug of the shoulders. It would not occur to any one to base a belief which has such far-reaching implications on an isolated observation. But I can assure you that this is not the only case in my experience. I have collected a whole set of such prophecies, and I have the impression that in every instance the fortune-teller has only given expression to the thoughts, and particularly to the secret wishes, of his clients; so that we are justified in analysing such prophecies as if they were the subjective productions, phantasies, or dreams of the people concerned. Naturally not all cases have equal evidential value, nor in all cases is it equally possible to rule out more rational explanations; but taking all the evidence together there remains a heavy weight of probability in favour of the reality of thought-transference. The importance of the matter would justify my putting all my cases before you; but I cannot do that because the material would be of inordinate length and would inevitably involve a breach of professional secrecy. I will try to salve my conscience as far as possible by giving you one or two more examples.

One day a very intelligent young man came to see me. He was a student, preparing for his final medical examination; but he was not in a condition to take it, because, as he complained, he had lost all his interests, all power of concentration, and even the faculty of a well-ordered memory. The history of this paralysing condition was soon unravelled: he had fallen ill after carrying through a line of conduct which had necessitated great self-discipline. He had a sister towards whom he felt, just as she did towards him, an intense but always restrained affection. They had often enough said to each other: "What a shame it is that we cannot marry!" An unobjectionable man had fallen in love with the sister, and she had returned his feeling, but her parents would not give their consent to the union. The couple had

turned to my patient for help, and he had not refused it. He had enabled them to correspond with each other, and it had been due to his influence that the parents had eventually been persuaded to give their consent. While they were engaged, a chance occurrence had taken place, whose significance it is easy to guess. He and his future brother-in-law undertook a difficult climb without a guide; they lost their way and were in danger of never returning alive. Shortly after the marriage of his sister he had fallen into his present state of mental exhaustion.

When he had become able to work as a result of psycho-analysis, he left me to take his examination; but after he had got through it he came back to me in the autumn of the same year for a short period. He then told me of a remarkable experience which he had had before the summer. In his university town there lived a fortune-teller, who carried on a very successful practice there. Even the princes of the reigning house used to consult her regularly before undertaking any important step. The way in which she worked was very simple. She asked for the facts concerning the birth of the person involved, but wanted to know nothing else about him, not even his name. She then consulted her astrological books, made long calculations and in the end made a prophecy about him. My patient decided to make use of her secret arts in connection with his brother-in-law. He visited her and gave her the requisite data about him. After she had made her calculations she pronounced the following prophecy: "This person will die in July or August of this year of poison from eating crabs or oysters." My patient finished his story by explaining: "And that really was marvellous!"

From the very beginning, I had listened to his story without enthusiasm; and after this exclamation I permitted myself to ask: "What is it that makes you find this prophecy so marvellous? We have already reached the late autumn, and your brother-in-law is not dead yet, or you would have told me long ago. The prophecy therefore has not come true." "The prophecy—no," he said, "but the remarkable thing is this. My brother-in-law is passionately fond of crabs and oysters, and last summer, that is to say before my visit to the fortune-teller, he was poisoned by eating oysters, and nearly died of it." What could I say about it? I could only feel distressed that such an intelligent man, and, moreover, one who had a satisfactory analysis behind him, should not have

seen through the whole thing more clearly. For my part, before I believe that one can calculate the onset of shellfish-poisoning by consulting astrological tables, I would rather suppose that my patient had not yet overcome his hatred towards his rival, the repression of which had caused his own illness, and that the lady astrologer simply gave voice to his own hope: "People never give up such tastes, and one day they will really be the end of him." I admit that I can find no other explanation for this case, except perhaps that my patient was making a joke at my expense. But neither then nor later did he give me any grounds for such a suspicion, and he seemed to mean quite seriously what he said.

Here is another case. A young man of good position had a mistress, and showed a remarkable obsession in his relations with her. From time to time he was impelled to wound her feelings with insulting remarks till she was reduced to despair. When he had got her into this condition he felt relieved, made it up with her, and gave her presents. But now he wanted to free himself from her, for the obsession was becoming a worry to him: he noticed that his professional life was suffering from the relationship, and wanted to have a wife and family of his own. Since, however, he could not get away from his mistress by his own efforts, he came to analysis for help. After one of these scenes, which occurred during the analysis, he got her to write him a few words on a piece of paper and showed it to a graphologist. The information he received from him was to the effect that this was the handwriting of a person in the depths of despair, who would certainly commit suicide in the course of the next few days. That event did not indeed come about, for the lady remained alive, but the analytical treatment enabled him to free himself from his fetters; he left the lady and turned his attentions to a young girl who he thought would make him a good wife. Soon afterwards he had a dream which could only be explained as due to an incipient doubt about the young girl's worth. He obtained a specimen of her handwriting as well, which he placed before the same authority, and received a judgment on it which confirmed his anxieties. He therefore gave up his intention of making her his wife.

To estimate the reports of the handwriting expert, and particularly the first one, at their proper value, one must know something of the private history of our subject. In his early adolescent years he was madly in love with a

young woman, some years older than himself, in the passionate way that was characteristic of him. She rejected him, and he thereupon attempted suicide; nor can we doubt the seriousness of his intention. It was only by a miracle that he escaped death, and it was only after careful nursing that he recovered. But this reckless act made a deep impression upon the woman he was in love with; she responded to his attentions, and became his mistress. From that time onwards he had a deep attachment to her, and served her in a truly devoted manner. After more than two decades, when they had both lost something of their youth, the woman naturally more than he, he felt the need of detaching himself from her; he wanted to be free, to lead his own life, and to have a house and family of his own. And at the same time that he felt this dissatisfaction, there sprang up in him the long-suppressed need for revenge upon her. Just as at first he had tried to commit suicide himself, because she rejected him, so now he wanted to have the satisfaction of seeing her seek destruction because he was leaving her. But his love was still too strong for this wish to become conscious; nor was he able to behave badly enough to her to drive her to commit suicide. In this frame of mind, he took on the mistress whom I first mentioned as a kind of whipping-boy, in order to satisfy his thirst for revenge *in corpore vili*, and inflicted on her all the injuries calculated to produce in her the effect he desired to produce in the woman he loved. The fact that the revenge was actually directed towards the latter was only betrayed by the circumstances that he made her a confederate and advisor in his love-affair, instead of hiding his lapse from her. The unfortunate woman, who had sunk from the position of giving favours to that of receiving them, probably suffered from his confidences more than the new mistress did from his brutality. The obsession of which he complained in reference to the latter, and which brought him under analytic treatment, had naturally been transferred from his first mistress to her; it was from his first mistress that he wanted to free himself and could not. I am no handwriting expert, and I do not think much of the art of guessing character from handwriting; still less do I believe in the possibility of foretelling the future of the writer in that way. You see, however, that, whatever one may think of the value of graphology, it is undeniable that the expert, when he promised that the writer of the specimen which had been brought to him would

commit suicide during the next few days, had once more only brought to light a very strong secret wish on the part of the person who was asking his opinion. Something similar happened in the case of the second report, only that here we are not concerned with an unconscious wish; here it was the incipient doubts and anxieties of the inquirer that found overt expression through the mouth of the handwriting specialist. I may add that my patient was able, with the help of analysis, to make a love-choice outside the magic circle within which he had been spell-bound.

Ladies and Gentlemen—You have now heard what dream-interpretation and psycho-analysis in general can do for occultism. You have seen by means of examples that, through the application of psycho-analytic theory, occult phenomena have been revealed which would otherwise have remained unrecognized. The question which doubtless interests you most, whether we ought to believe in the objective reality of the phenomena, is one which psycho-analysis cannot answer directly; but at least the material which it has helped to bring to light is favourable to an affirmative reply. But your interest will not stop there. You will want to know to what conclusion that far richer vein of material, with which psycho-analysis has nothing whatever to do, leads us. There, however, I cannot follow you; it is no longer my province. The only thing I can do is to tell you of some observations, which at any rate have something to do with psycho-analysis in the sense that they were made during analytical treatment, and were perhaps rendered possible by means of it. I will give you one example, the one which left the strongest impression with me; it will be long-winded, and you will have to keep a number of details in your minds, and even so a great deal will have to be omitted which increased the evidential value of the observation. It is an instance in which the phenomena in which we are interested came to light quite obviously and did not have to be brought out by analysis. In discussing it, however, we shall not be able to do without analysis. But I ought to warn you beforehand that even this example of apparent thought-transference in the analytic situation is not proof against all objections, and does not warrant unconditional acceptance of the reality of occult phenomena.

The story is this. One autumn day in the year 1919, at about 10.45 A.M., Dr. David Forsyth, who had just arrived from London,

sent in his card while I was working with a patient. (My respected colleague from the University of London will, I feel sure, not think I am being indiscreet if I tell you that he came to me for some months to be initiated into the mysteries of psycho-analytical technique.) I had only time to say "How do you do?" and arrange an appointment for later on. Dr. Forsyth had a special claim upon my interest; for he was the first foreigner who came to me after the isolation of the war years, and seemed to be a harbinger of better times. Soon after this, at eleven o'clock, my next patient arrived, a Mr. P, an intelligent and charming man of between forty and fifty, who had come to me because he experienced difficulties in sexual intercourse with women. In his case there was no prospect of bringing about a cure, and I had long ago suggested that he should break off the treatment; but he had preferred to continue it, obviously because he felt comfortable in a well-tempered father-transference upon myself. Money played no part at this time, because there was too little of it about. The hours I spent with him were stimulating for me as well, and a relaxation, and so, setting aside the strict rules of medical etiquette, we were going on with the analytic treatment for a specified length of time.

On this particular day, P reverted to his attempts at sexual intercourse with women, and mentioned once more the pretty, piquante girl, in poor circumstances, with whom he might have been successful if only the fact of her virginity had not frightened him off from taking any serious steps. He had often spoken of her, but that day he told me for the first time that she, though naturally she had not the slightest idea of the real grounds of his difficulty, used to call him Mr. Foresight (*Vorsicht*). I was much struck by this piece of information; Dr. Forsyth's card was beside me, and I showed it to him.

These are the facts. I dare say they will seem to you to be rather thin; but if you will have patience you will find that there is more to come.

P had spent some years of his youth in England, and had retained a lasting interest in English literature. He possessed a well-stocked library of English books, which he used to lend me, and it is to him that I owe my acquaintance with authors such as Arnold Bennett and Galsworthy, of whose works I had so far read but little. One day he lent me a novel by Galsworthy called *The Man of Property*, the sub-

ject of which is an imaginary family named Forsyte. Galsworthy's imagination was obviously captured by this creation of his, because in the later stories he repeatedly went back to members of this family, and eventually collected all the stories which had to do with them under the heading of *The Forsyte Saga*. Only a few days before the event I am telling you about, P had brought me a new volume out of this series. The name Forsyte, and all that it typified for the author, had played a part in my conversations with P; it had become a part of the private language which so easily grows up between two people who see each other regularly. Now the name *Forsyte* out of the novels is not very different from that of my visitor *Forsyth* (as pronounced by a German, indeed, they are hardly distinguishable), and the expressive English word *foresight*, which means *Voraussicht* or *Vorsicht*, would be pronounced in the same way. P had, therefore, produced from his own personal experiences a name that was in my mind at the same time on account of a circumstance quite unknown to him.

As you see, we are making some progress. But I think we shall be even more strongly impressed by this remarkable occurrence and get some sort of insight into the condition of its origin, if we turn the light of analysis on to two other associations which P brought up during the same hour.

First: One day in the preceding week I was expecting Mr. P at 11 o'clock, but he had not appeared, and I went out to pay a call on Dr. Anton von Freund at his pension. I was surprised to find that Mr. P lived on another floor of the same house in which the pension was. Referring to this later, I told P that I had in a sense paid him a visit at his house; but I am absolutely certain that I did not mention the name of the person whom I had visited in the pension, and now, soon after the mention of Mr. Foresight, he asked me the following question: "Is the lady called Freud-Ottorego who gives the English course at the Volks-universität your daughter by any chance?" And for the first time in our long acquaintance he let slip the distorted form of my name, to which officials, clerks, and printers have accustomed me; instead of Freud, he said Freund.

Secondly: At the end of the hour he told me a dream out of which he had awakened with a feeling of anxiety, a regular *Alptraum* (nightmare) he called it. He added that he had recently forgotten the English word for it, and

had told some one who had asked him, that the English for *Alptraum* was "a mare's nest." That is of course, absurd, because "a mare's nest" means nothing of the sort, and the correct translation of *Alptraum* is "nightmare." This association seemed to have nothing more in common with the others than the element of *English*; but he reminded me of a trivial occurrence which had happened about a month before. P was sitting in my room with me, when there appeared quite unexpectedly another welcome guest from London, Dr. Ernest Jones, whom I had not seen for a long time. I nodded to him to go into my other room until I had finished with P. The latter recognized him at once, however, from a photograph of him which hung in the waiting-room, and even asked to be introduced to him. Now Jones is the author of a monograph on the nightmare. I did not know whether P was acquainted with the book; he avoided reading analytical literature.

At this point I should like to consider what analytical understanding we can obtain of P's associations and their motivations. P had the same attitude towards the name Forsythe as I had; it meant the same to him as it did to me, and in fact it was to him that I owed my knowledge of the name. The remarkable thing was that he brought this name into the analysis immediately after it had acquired another meaning for me through a recent experience, namely the arrival of the physician from London. But perhaps not less interesting is the way in which the name came up in his analytical hour. He did not say: "Now the name Forsythe, out of the novels you have read, comes into my mind," but, without any conscious reference to this source, he managed to weave it into his own personal experiences and brought it to the surface in that way—a thing which might have happened long before, but which had not as a matter of fact occurred until now. At this juncture, however, he said: "I am a Forsythe, too, for that is what the girl called me." One cannot mistake the mixture of exacting jealousy and plaintive self-depreciation which finds expression in this utterance. We shall not go far wrong if we complete it thus: "I am hurt that your thoughts should be so much wrapped up in this newcomer. Come back to me; after all, I am a Forsythe too—or rather only a Mr. Foresight, as the girl called me." And now, starting from the idea of *English*, his train of thought worked back to two earlier situations, which might very well have aroused the same jealousy

in him. "A few days ago you paid a visit at my house, but, alas, it was not to me, it was to a Herr von Freund." This idea made him distort the name Freud into Freund. The name Freud-Ottorego from the lecture list came in, because as the name of a teacher of English it paved the way for the manifest association. And now the memory of another visitor of a few weeks back presented itself, a visitor towards whom he certainly felt just as jealous, this visitor (Dr. Jones) was at the same time in a superior position to him, because he could write a book about nightmares, while the best he could do was to have nightmares himself. The allusion to his mistake about the meaning of a "mare's nest" belonged to the same connection; it must mean: "I am not a proper Englishman after all, any more than I am a proper Forsyth."

Now it could not be said that his jealous feelings were either inappropriate or incomprehensible. He had already been made aware that his analysis, and with it our relations, would come to an end as soon as foreign pupils and patients began to return to Vienna; and this is actually what happened shortly afterwards. But what we have just been doing has been a piece of analytical work: the explanation of three ideas which were brought up in the same hour and were determined by the same motivation. This has not much to do with the question whether these ideas could have been produced without thought-transference or not. The latter question applies to each of the three ideas, and can thus be divided into three separate questions. Could P have known that Dr. Forsyth had just paid his first visit to me? Could he have known the name of the person whom I visited in his house? Did he know that Dr. Jones had written a book about nightmares? Or was it only my knowledge of these things which was displayed in the ideas that came into his head? Whether this observation of mine leads to a conclusion in favour of thought-transference depends on the answer which is given to these separate questions. Let us leave the first question aside for the moment, as the two others are easier to deal with. The case of the visit to the pension strikes one at first sight as being very convincing. I am quite sure that in my short humorous mention of my visit to his house I did not mention any name; I think it is most improbable that P made inquiries in the pension to discover the name of the person I had called on; in fact, I believe that he never knew of his existence. But the evidential value of this case is undermined by a chance factor.

The man whom I had been to see in the pension was not only *called* Freund, but was indeed a true friend to us all. It was he whose generosity had made possible the founding of our publishing-house. His early death, and that of Karl Abraham a few years later, were the most serious misfortunes which have befallen the development of psycho-analysis. It is possible, therefore, that I said to Mr. P: "I have been visiting a *friend* at your house," and with this possibility the occult interest of the second association evaporates.

The impression made by the third association, too, soon fades. Could P have known that Jones had published a monograph on the nightmare, seeing that he never read analytical literature? Yes, he could. He possessed books issued by our publishing-house, and he might certainly have seen the titles of new publications printed on the covers. It cannot be proved, but it cannot be disproved. Along this road, then, we can come to no decision. This example of mine, I regret to say, is open to the same objections as so many others. It was written down too late, and came up for discussion at a time when I was not seeing Mr. P any more, and could not ask him any further questions.

Let us return to the first association, which even by itself would support the alleged occurrence of thought-transference. Could P have known that Dr. Forsyth had been with me a quarter of an hour before him? Could he even have known of his existence or of his presence in Vienna? We must not give way to the temptation to answer both questions straight off in the negative. I might very well have told Mr. P I was expecting a physician from England for training in analysis, the first dove after the deluge. This might have happened in the summer of 1919; Dr. Forsyth had made arrangements with me by letter, months before his arrival. I may even have mentioned his name, though that is most improbable. In view of the other association which the name had for us both, the mention of it would inevitably have led to a conversation of which some trace at least would have been preserved in my memory. Nevertheless such a conversation may have taken place and I may have totally forgotten it, so that it became possible for the mention of Mr. Foresight in the analytical hour to strike me as miraculous. If one regards oneself as a sceptic, it is well from time to time to be sceptical about one's scepticism. Perhaps I too have that secret leaning towards the miraculous

which meets the production of occult phenomena half-way.

Even if one part of this miraculous occurrence is thus explained away, we still have another part on our hands, and that the most difficult part of all. Granted that Mr. P knew that there was such a person as Dr. Forsyth and that he was expected in Vienna in the autumn, how was it that my patient became sensitive to him on the very day of his arrival and immediately after his first visit? We might say that it was chance, that is, we might leave it unexplained; but I have mentioned the two other ideas which occurred to Mr. P precisely in order to exclude chance, in order to show you that he really was occupied with jealous thoughts directed against people who visited me, and whom I visited. Or, if we are anxious not to overlook anything even remotely possible, we might suppose that P noticed that I was in a state of unusual excitement, a state of which I was certainly not aware, and that he drew his inference from that. Or that Mr. P, who after all had arrived only a quarter of an hour after the Englishman, had met him in the immediate neighbourhood of my house, that he had recognized him from his typically English appearance, and with his jealous feelings on the alert, had immediately thought: "Ah, there is Dr. Forsyth, whose arrival means the end of my analysis; and probably he has just left the Professor." I cannot go any further into these rationalistic hypotheses. We are left once more with a *non liquet*, but I must confess that here too I feel that the balance is in favour of thought-transference. For the matter of that, I am certainly not the only person who has met with *occult* phenomena in the analytic situation. Helene Deutsch in 1926 reported some observations of the same kind, and studied the way in which they were conditioned by the relation of transference between the patient and the analyst.

I am sure that you will not be satisfied with my position with regard to this problem—not completely convinced and yet ready to be convinced. Perhaps you will say to yourselves: "Here is another example of a person who has all his life been a steady-going man of science, and is now in his old age becoming weak-minded, religious, and credulous." I know that some great names belong in that category, but you must not reckon mine among them. At least I have not grown religious, and I hope I have not become credulous. If one has humbled one-

self all one's life long in order to avoid painful conflict with facts, one tends to keep one's back bowed in one's old age before any new facts which may appear. No doubt you would far prefer that I should hold fast to a moderate theism, and turn relentlessly against anything occult. But I am not concerned to seek any one's favour, and I must suggest to you that you should think more kindly of the objective possibility of thought-transference and therefore also of telepathy.

You must not forget that I have only dealt with the problem here in so far as one can approach it from the direction of psycho-analysis. When I turned my thoughts towards it more than ten years ago, I too felt afraid lest our scientific outlook might be endangered and have to give way to spiritualism or mysticism if occult phenomena were proved to be true. I think otherwise now; it seems to me that one is displaying no great trust in science if one cannot rely on it to accept and deal with any occult hypothesis that may turn out to be correct. And as regards thought-transference in particular, it would seem actually to favour the extension of the scientific (or, as opponents would say, mechanistic) way of thinking on to the elusive world of the mind. For the telepathic process is supposed to consist in a mental act of one person giving rise to the same mental act in another. What lies between the two mental acts may very well be a physical process, into which the mental process transforms itself at one end and which is transformed back into the same mental process at the other. The analogy with other transformations, such as speaking and hearing across the telephone, is an obvious one. And think what it would mean if one could get hold of this physical equivalent of the mental act! I should like to point out that by inserting the unconscious between the physical and what has hitherto been regarded as the mental, psycho-analysis has prepared the way for the acceptance of such processes as telepathy. If one gets used to the idea of telepathy, one can account for a great deal by means of it, so far, of course, only in imagination. It is a familiar fact that we have no notion of how the communal will of the great insect states comes about. Possibly it works by means of mental transference of this direct kind. One is led to conjecture that this may be the original archaic method by which individuals understood one another, and which has been pushed into the background in the course of phylogenetic de-

velopment by the better method of communication by means of signs apprehended by the sense organs. But such older methods may have persisted in the background, and may still manifest themselves under certain conditions: for example, in crowds roused to a state of passionate excitement. All of this is highly speculative and full of unsolved problems, but there is no need to be alarmed by it.

If telepathy is a real process, one may, in spite of the difficulty of proof, suppose that it is quite a common phenomenon. It would fit in with our expectations if we could show that it occurs particularly in the mental life of children. One is reminded of the frequent fear felt by children that their parents know all their thoughts without having been told them—a fear which is a complete parallel to, and perhaps the origin of, the belief of adults in the omniscience of God. A short time ago a trustworthy observer, Dorothy Burlingham, published some findings in a paper called "Child Analysis and the Mother," which, if they are confirmed, must put an end to any remaining doubts of the reality of thought transference. She took as her starting-point a number of those cases (now no longer rare) in which a mother and child are being analysed at the same time, and reported such remarkable phenomena as the following. One day in her analytic hour the mother was talking about a gold coin which had figured in one of her childhood experiences. Immediately afterwards, when she had returned home, her little ten-year-old boy came into her room and brought her a gold coin to keep for him. She was astonished and asked him where he had got it from. He had been given it on his birthday, but that was several months ago, and there was no reason why the child should have remembered the gold coin just then. The mother told the analyst about the coincidence, and asked her to try to find out from the child why he had behaved in this way. But the analysis of the child elicited nothing; the action had made its way into the child's life that day like a foreign body. A few weeks later the mother was sitting at her writing table, in order to make a note of the occurrence, as she had been asked to do. At that moment the boy came in and asked for the gold coin back, saying that he wanted to take it to show his analyst. Once more the child's analysis disclosed nothing that led up to the wish.

And with that we return to our starting-point—the study of psycho-analysis,

## LECTURE 31

## THE ANATOMY OF THE MENTAL PERSONALITY

LADIES AND GENTLEMEN: I am sure you all recognize in your dealings, whether with persons or things, the importance of your starting-point. It was the same with psycho-analysis: the course of development through which it has passed, and the reception which it has met with have not been unaffected by the fact that what it began working upon was the symptom, a thing which is more foreign to the ego than anything else in the mind. The symptom has its origin in the repressed; it is, as it were, the representative of the repressed in relation to the ego; the repressed is a foreign territory to the ego, an internal foreign territory, just as reality is—you must excuse the unusual expression—an external foreign territory. From the symptom the path of psycho-analysis led to the unconscious, to the life of the instincts, to sexuality, and it was then that psycho-analysis was met by illuminating criticisms to the effect that man is not merely a sexual being but has nobler and higher feelings. It might have been added that, supported by the consciousness of those higher feelings, he often allowed himself the right to think nonsense and to overlook facts.

You know better than that. From the very beginning our view was that men fall ill owing to the conflict between the demands of their instincts and the internal resistance which is set up against them; not for a moment did we forget this resisting, rejecting and repressing factor, which we believed to be furnished with its own special forces, the ego-instincts, and which corresponds to the ego of popular psychology. The difficulty was that, since the progress of all scientific work is necessarily laborious, psycho-analysis could not study every part of the field at once or make a pronouncement on every problem in one breath. At last we had got so far that we could turn our attention from the repressed to the repressing forces, and we came face to face with the ego, which seemed to need so little explanation, with the certain expectation that there, too, we should find things for which we could not have been prepared; but it was not easy to find a first method of approach. That is what I am going to talk to you about today.

Before I start, I may tell you that I have a suspicion that my account of the psychology of the ego will affect you differently than the introduction into the psychological underworld

that preceded it. Why that should be the case, I cannot say for certain. My original explanation was that you would feel that, whereas hitherto I have been telling you in the main about facts, however strange and odd they might appear, this time you would be listening chiefly to theories, that is to say, speculations. But that is not quite true; when I weighed the matter more carefully I was obliged to conclude that the part played by intellectual manipulation of the facts is not much greater in our ego-psychology than it was in the psychology of the neuroses. Other explanations turned out to be equally untenable, and I now think that the character of the material itself is responsible, and the fact that we are not accustomed to dealing with it. Anyhow I shall not be surprised if you are more hesitant and careful in your judgment than you have been hitherto.

The situation in which we find ourselves at the beginning of our investigation will itself suggest the path we have to follow. We wish to make the ego the object of our study, our own ego. But how can we do that? The ego is the subject *par excellence*, how can it become the object? There is no doubt, however, that it can. The ego can take itself as object, it can treat itself like any other object, observe itself, criticize itself, and do Heaven knows what besides with itself. In such a case one part of the ego stands over against the other. The ego can, then, be split; it splits when it performs many of its functions, at least for the time being. The parts can afterwards join up again. After all that is saying nothing new; perhaps it is only underlining more than usual something that every one knows already. But on the other hand we are familiar with the view that pathology, with its magnification and exaggeration, can make us aware of normal phenomena which we should otherwise have missed. Where pathology displays a breach or a cleft, under normal conditions there may well be a link. If we throw a crystal to the ground, it breaks, but it does not break haphazard; in accordance with the lines of cleavage it falls into fragments, whose limits were already determined by the structure of the crystal, although they were invisible. Psychotics are fissured and splintered structures such as these. We cannot deny them a measure of that awe with which madmen were regarded by the peoples of ancient times. They have turned away from external reality, but for that very reason they know more of internal psychic reality and can

tell us much that would otherwise be inaccessible to us. One group of them suffer what we call delusions of observation. They complain to us that they suffer continually, and in their most intimate actions, from the observation of unknown powers or persons, and they have hallucinations in which they hear these persons announcing the results of their observations: "Now he is going to say this; now he is dressing himself to go out," and so on. Such observation is not the same thing as persecution, but it is not far removed from it. It implies that these persons distrust the patient, and expect to catch him doing something that is forbidden and for which he will be punished. How would it be if these mad people were right, if we all of us had an observing function in our egos threatening us with punishment, which, in their case, had merely become sharply separated from the ego and had been mistakenly projected into external reality?

I do not know whether it will appeal to you in the same way as it appeals to me. Under the strong impression of this clinical picture, I formed the idea that the separating off of an observing function from the rest of the ego might be a normal feature of the ego's structure; this idea has never left me, and I was driven to investigate the further characteristics and relations of the function which had been separated off in this way. The next step is soon taken. The actual content of the delusion of observation makes it probable that the observation is only a first step towards conviction and punishment, so that we may guess that another activity of this function must be what we call conscience. There is hardly anything that we separate off from our ego so regularly as our conscience and so easily set over against it. I feel a temptation to do something which promises to bring me pleasure, but I refrain from doing it on the ground that *my conscience will not allow it*. Or I allow myself to be persuaded by the greatness of the expectation of pleasure into doing something against which the voice of my conscience has protested, and after I have done it my conscience punishes me with painful reproaches, and makes me feel remorse for it. I might simply say that the function which I am beginning to distinguish within the ego is the conscience; but it is more prudent to keep that function as a separate entity and assume that conscience is one of its activities, and that the self-observation which is necessary as a preliminary to the judicial aspect of conscience is another. And since the process of recognizing

a thing as a separate entity involves giving it a name of its own, I will henceforward call this function in the ego the *super-ego*.

At this point I am quite prepared for you to ask scornfully whether our ego-psychology amounts to no more than taking everyday abstractions literally, magnifying them, and turning them from concepts into things—which would not be of much assistance. My answer to that is that in ego-psychology it will be difficult to avoid what is already familiar, and that it is more a question of arriving at new ways of looking at things and new groupings of the facts than of making new discoveries. I will not ask you, therefore, to abandon your critical attitude but merely to await further developments. The facts of pathology give our efforts a background for which you will look in vain in popular psychology. I will proceed. No sooner have we got used to the idea of this super-ego, as something which enjoys a certain independence, pursues its own ends, and is independent of the ego as regards the energy at its disposal, than we are faced with a clinical picture which throws into strong relief the severity, and even cruelty, of this function, and the vicissitudes through which its relations with the ego may pass. I refer to the condition of melancholia, or more accurately the melancholic attack, of which you must have heard often enough, even if you are not psychiatrists. In this disease, about whose causes and mechanism we know far too little, the most remarkable characteristic is the way in which the super-ego—you may call it, but in a whisper, the *conscience*—treats the ego. The melancholic during periods of health can, like any one else, be more or less severe towards himself; but when he has a melancholic attack, his super-ego becomes over-severe, abuses, humiliates, and ill-treats his unfortunate ego, threatens it with the severest punishments, reproaches it for long forgotten actions which were at the time regarded quite lightly, and behaves as though it had spent the whole interval in amassing complaints and was only waiting for its present increase in strength to bring them forward, and to condemn the ego on their account. The super-ego has the ego at its mercy and applies the most severe moral standards to it; indeed it represents the whole demands of morality, and we see all at once that our moral sense of guilt is the expression of the tension between the ego and the super-ego. It is a very remarkable experience to observe morality, which was ostensibly conferred on us by God

and planted deep in our hearts, functioning as a periodical phenomenon. For after a certain number of months the whole moral fuss is at an end, the critical voice of the super-ego is silent, the ego is reinstated, and enjoys once more all the rights of man until the next attack. Indeed in many forms of the malady something exactly the reverse takes place during the intervals; the ego finds itself in an ecstatic state of exaltation, it triumphs, as though the super-ego had lost all its power or had become merged with the ego, and this liberated, maniac ego gives itself up in a really uninhibited fashion, to the satisfaction of all its desires. Happenings rich in unsolved riddles!

You will expect me to do more than give a mere example in support of my statement that we have learnt a great deal about the formation of the super-ego, that is, of the origin of conscience. The philosopher Kant once declared that nothing proved to him the greatness of God more convincingly than the starry heavens and the moral conscience within us. The stars are unquestionably superb, but where conscience is concerned God has been guilty of an uneven and careless piece of work, for a great many men have only a limited share of it or scarcely enough to be worth mentioning. This does not mean, however, that we are overlooking the fragment of psychological truth which is contained in the assertion that conscience is of divine origin! but the assertion needs interpretation. Conscience is no doubt something within us, but it has not been there from the beginning. In this sense it is the opposite of sexuality, which is certainly present from the very beginning of life, and is not a thing that only comes in later. But small children are notoriously a-moral. They have no internal inhibitions against their pleasure-seeking impulses. The rôle, which the super-ego undertakes later in life, is at first played by an external power, by parental authority. The influence of the parents dominates the child by granting proofs of affection and by threats of punishment, which, to the child, mean loss of love, and which must also be feared on their own account. This objective anxiety is the forerunner of the later moral anxiety; so long as the former is dominant one need not speak of super-ego or of conscience. It is only later that the secondary situation arises, which we are far too ready to regard as the normal state of affairs; the external restrictions are introjected, so that the super-ego takes the place of the parental function, and thenceforward observes,

guides, and threatens the ego in just the same way as the parents acted to the child before.

The super-ego, which in this way has taken over the power, the aims and even the methods of the parental function, is, however, not merely the legatee of parental authority, it is actually the heir of its body. It proceeds directly from it, and we shall soon learn in what way this comes about. First, however, we must pause to consider a point in which they differ. The super-ego seems to have made a one-sided selection, and to have chosen only the harshness and severity of the parents, their preventive and punitive functions, while their loving care is not taken up and continued by it. If the parents have really ruled with a rod of iron, we can easily understand the child developing a severe super-ego, but, contrary to our expectations, experience shows that the super-ego may reflect the same relentless harshness even when the up-bringing has been gentle and kind, and avoided threats and punishment as far as possible. We shall return to this contradiction later, when we are dealing with the transmutation of instincts in the formation of the super-ego.

I cannot tell you as much as I could wish about the change from the parental function to the super-ego, partly because that process is so complicated that a description of it does not fit into the framework of a set of introductory lectures such as these, and partly because we ourselves do not feel that we have fully understood it. You will have to be satisfied, therefore, with the following indications. The basis of the process is what we call an *identification*, that is to say, that one ego becomes like another, one which results in the first ego behaving itself in certain respects in the same way as the second; it imitates it, and as it were takes it into itself. This identification has been not inappropriately compared with the oral cannibalistic incorporation of another person. Identification is a very important kind of relationship with another person, probably the most primitive, and is not to be confused with object-choice. One can express the difference between them in this way: when a boy identifies himself with his father, he wants to *be like* his father; when he makes him the object of his choice, he wants to *have* him, to possess him; in the first case his ego is altered on the model of his father, in the second case that is not necessary. Identification and object-choice are broadly speaking independent of each other; but one can identify oneself with a person, and

alter one's ego accordingly, and take the same person as one's sexual object. It is said that this influencing of the ego by the sexual object takes place very often with women, and is characteristic of femininity. With regard to what is by far the most instructive relation between identification and object-choice, I must have given you some information in my previous lectures. It can be as easily observed in children as in adults, in normal as in sick persons. If one has lost a love-object or has had to give it up, one often compensates oneself by identifying oneself with it; one sets it up again inside one's ego, so that in this case object-choice regresses, as it were, to identification.

I am myself not at all satisfied with this account of identification, but it will suffice if you will grant that the establishment of the super-ego can be described as a successful instance of identification with the parental function. The fact which is decisively in favour of this point of view is that this new creation of a superior function within the ego is extremely closely bound up with the fate of the Oedipus complex, so that the super-ego appears as the heir of that emotional tie, which is of such importance for childhood. When the Oedipus complex passes away, the child must give up the intense object-cathexes which it has formed towards its parents, and to compensate for this loss of object, its identifications with its parents, which have probably long been present, become greatly intensified. Identifications of this kind, which may be looked on as precipitates of abandoned object-cathexes, will recur often enough in the later life of the child; but it is in keeping with the emotional importance of this first instance of such a transformation that its product should occupy a special position in the ego. Further investigation also reveals that the super-ego does not attain to full strength and development if the overcoming of the Oedipus complex has not been completely successful. During the course of its growth, the super-ego also takes over the influence of those persons who have taken the place of the parents, that is to say of persons who have been concerned in the child's upbringing, and whom it has regarded as ideal models. Normally the super-ego is constantly becoming more and more remote from the original parents, becoming, as it were, more impersonal. Another thing that we must not forget is that the child values its parents differently at different periods of its life. At the time at which the Oedipus complex makes way

for the super-ego, they seem to be splendid figures, but later on they lose a good deal of their prestige. Identifications take place with these later editions of the parents as well, and regularly provide important contributions to the formation of character; but these only affect the ego, they have no influence on the super-ego, which has been determined by the earliest parental imagos.

I hope you will by now feel that in postulating the existence of a super-ego I have been describing a genuine structural entity, and have not been merely personifying an abstraction, such as conscience. We have now to mention another important activity which is to be ascribed to the super-ego. It is also the vehicle of the ego-ideal, by which the ego measures itself, towards which it strives, and whose demands for ever-increasing perfection it is always striving to fulfil. No doubt this ego-ideal is a precipitation of the old idea of the parents, an expression of the admiration which the child felt for the perfection which it at that time ascribed to them. I know you have heard a great deal about the sense of inferiority which is said to distinguish the neurotic subject. It crops up especially in the pages of works that have literary pretensions. A writer who brings in the expression *inferiority-complex* thinks he has satisfied all the demands of psycho-analysis and raised his work on to a higher psychological plane. As a matter of fact the phrase *inferiority-complex* is hardly ever used in psycho-analysis. It does not refer to anything which we regard as simple, let alone elementary. To trace it back to the perception in oneself of some organic disability or other, as the school of so-called Individual Psychologists like to do, seems to us a short-sighted error. The sense of inferiority has a strong erotic basis. The child feels itself inferior when it perceives that it is not loved, and so does the adult as well. The only organ that is really regarded as inferior is the stunted penis—the girl's clitoris. But the major part of the sense of inferiority springs from the relationship of the ego to its super-ego, and, like the sense of guilt, it is an expression of the tension between them. The sense of inferiority and the sense of guilt are exceedingly difficult to distinguish. Perhaps we should do better if we regarded the former as the erotic complement to the sense of moral inferiority. We have paid but little attention to such questions of conceptual differentiation in psycho-analysis.

Seeing that the inferiority-complex has become so popular, I shall venture to treat you to

a short digression. A historical personage of our own time, who is still living but who for the present has retired into the background, suffers from the mal-development of a limb caused by an injury at birth. A very well-known contemporary writer who has a predilection for writing the biographies of famous persons, has dealt with the life of the man to whom I am referring. Now if one is writing a biography, it is naturally very difficult to suppress the urge for psychological understanding. The author has therefore made an attempt to build up the whole development of his hero's character on the basis of a sense of inferiority, which was caused by his physical defect. While doing this he has overlooked a small but not unimportant fact. It is usual for mothers to whom fate has given a sickly or otherwise defective child to try to compensate for this unfair handicap with an extra amount of love. In the case we are speaking of, the proud mother behaved quite differently; she withdrew her love from the child on account of his disability. When the child grew up into a man of great power, he proved beyond all doubt by his behaviour that he had never forgiven his mother. If you will bear in mind the importance of mother-love for the mental life of the child, you will be able to make the necessary corrections in the inferiority-theory of the biographer.

But let us get back to the super-ego. We have allocated to it the activities of self-observation, conscience, and the holding up of ideals. It follows from our account of its origin that it is based upon an overwhelmingly important biological fact no less than upon a momentous psychological fact, namely the lengthy dependence of the human child on its parents and the Oedipus complex; these two facts, moreover, are closely bound up with each other. For us the super-ego is the representative of all moral restrictions, the advocate of the impulse towards perfection, in short it is as much as we have been able to apprehend psychologically of what people call the "higher" things in human life. Since it itself can be traced back to the influence of parents, teachers, and so on, we shall learn more of its significance if we turn our attention to these sources. In general, parents and similar authorities follow the dictates of their own super-egos in the upbringing of children. Whatever terms their ego may be on with their super-ego, in the education of the child they are severe and exacting. They have forgotten the difficulties of their own childhood, and are glad to be able to identify themselves

fully at last with their own parents, who in their day subjected them to such severe restraints. The result is that the super-ego of the child is not really built up on the model of the parents, but on that of the parents' super-ego. When it takes over the same content, it becomes the vehicle of tradition and of all the age-long values which have been handed down in this way from generation to generation. You may easily guess what great help is afforded by the recognition of the super-ego in understanding the social behaviour of man, in grasping the problem of delinquency, for example, and perhaps, too, in providing us with some practical hints upon education. It is probable that the so-called materialistic conceptions of history err in that they underestimate this factor. They brush it aside with the remark that the *ideologies* of mankind are nothing more than resultants of their economic situation at any given moment or superstructures built upon it. That is the truth, but very probably it is not the whole truth. Mankind never lives completely in the present; the ideologies of the super-ego perpetuate the past, the traditions of the race and the people, which yield but slowly to the influence of the present and to new developments, and, so long as they work through the super-ego, play an important part in man's life, quite independently of economic conditions.

In 1921, I tried to apply the distinction between the ego and the super-ego to the study of group psychology. I reached a formula, which ran like this: A psychological group is a collection of individuals who have introduced the same person into their super-ego, and on the basis of this common factor have identified themselves with one another in their ego. This, naturally, only holds for groups who have a leader. If we could find more applications of this kind, the hypothesis of the super-ego would lose all its strangeness for us, and we should be entirely relieved of the embarrassment which we cannot help feeling when, used as we are to the atmosphere of the underworld, we make excursions into the more superficial and higher planes of the mental apparatus. Of course we do not for a moment think that the last word on ego-psychology has been spoken with the demarcation of the super-ego. It is rather the beginning of the subject, but in this case it is not only the first step that is difficult.

But now another task awaits us, as it were at the opposite end of the ego. This question is raised by an observation which is made during analytic work, an observation which is, indeed,

an old one. As so often happens, it has taken a long time for its true value to be appreciated. As you are aware, the whole of psycho-analytic theory is in fact built up on the perception of the resistance exerted by the patient when we try to make him conscious of his unconscious. The objective indication of resistance is that his associations stop short or wander far away from the theme that is being discussed. He may also become subjectively aware of the resistance by experiencing painful feelings when he approaches the theme. But this last indication may be absent. In such a case, we say to the patient that we conclude from his behaviour that he is in a state of resistance, and he replies that he knows nothing about it and is only aware of a difficulty in associating. Experience shows that we were right, but, if so, his resistance too must have been unconscious, just as unconscious as the repressed material which we were trying to bring to the surface. Long ago we should have asked from which part of the mind such an unconscious resistance could operate. The beginner in psycho-analysis will be ready at once with the answer that it must be the resistance of the unconscious. An ambiguous and useless answer! If it means that the resistance operates from the repressed, then we must say: "Certainly not!" To the repressed we must rather ascribe a strong upward-driving force, an impulsion to get through to consciousness. The resistance can only be a manifestation of the ego, which carried through the repression at one time or other and is now endeavouring to keep it up. And that, too, was our earlier view. Now that we have posited a special function within the ego to represent the demand for restriction and rejection, i.e., the super-ego, we can say that repression is the work of the super-ego—either that it does its work on its own account or else that the ego does it in obedience to its orders. If now we are faced with the case where the patient under analysis is not conscious of his resistance, then it must be either that the super-ego and the ego can operate unconsciously in quite important situations, or, which would be far more significant, that parts of both ego and super-ego themselves are unconscious. In both cases we should have to take account of the disturbing view that the ego (including the super-ego) does not by any means completely coincide with the conscious, nor the repressed with the unconscious.

Ladies and Gentlemen—I feel I must have a little breathing space, which I expect you will

welcome with relief, and before I go on I must make an apology. Here am I giving you a supplement to the introduction to psycho-analysis which I started fifteen years ago, and I am behaving as though you yourselves had been doing nothing but psycho-analysis all that time. I know it is a monstrous supposition, but I am helpless, I have no alternative. The reason is that it is exceedingly difficult to give an insight into psycho-analysis to any one who is not himself a psycho-analyst. I assure you that we do not like to give the effect of being members of a secret society carrying on a secret science. And yet we have been obliged to recognize and state as our considered opinion that no one has a right to a say in psycho-analysis unless he has been through certain experiences which he can only have by being analysed himself. When I delivered my lectures to you fifteen years ago, I tried to let you off certain speculative parts of our theory, but it is with those very parts that are connected the new discoveries which I am going to speak of to-day.

Now let me return to my theme. With regard to the two alternatives—that the ego and the super-ego may themselves be unconscious, or that they may merely give rise to unconscious effects—we have for good reasons decided in favour of the former. Certainly, large portions of the ego and super-ego can remain unconscious, are, in fact, normally unconscious. That means to say that the individual knows nothing of their contents and that it requires an expenditure of effort to make him conscious of them. It is true, then, that ego and conscious, repressed and unconscious do not coincide. We are forced fundamentally to revise our attitude towards the problem of conscious and unconscious. At first we might be inclined to think very much less of the importance of consciousness as a criterion, since it has proved so untrustworthy. But if we did so, we should be wrong. It is the same with life: it is not worth much, but it is all that we have. Without the light shed by the quality of consciousness, we should be lost in the darkness of depth-psychology. Nevertheless we must try to orientate ourselves anew.

What is meant by *conscious*, we need not discuss; it is beyond all doubt. The oldest and best meaning of the word *unconscious* is the descriptive one; we call *unconscious* any mental process the existence of which we are obliged to assume—because, for instance, we infer it in some way from its effects—but of which we are not directly aware. We have the same re-

lation to that mental process as we have to a mental process in another person, except that it belongs to ourselves. If we want to be more accurate, we should modify the statement by saying that we call a process *unconscious* when we have to assume that it was active *at a certain time*, although *at that time* we knew nothing about it. This restriction reminds us that most conscious processes are conscious only for a short period; quite soon they become *latent*, though they can easily become conscious again. We could also say that they had become unconscious, if we were certain that they were still something mental when they were in the latent condition. So far we should have learnt nothing, and not even have earned the right to introduce the notion of the unconscious into psychology. But now we come across a new fact which we can already observe in the case of errors. We find that, in order to explain a slip of the tongue, for instance, we are obliged to assume that an intention to say some particular thing had formed itself in the mind of the person who made the slip. We can infer it with certainty from the occurrence of the speech-disturbance, but it was not able to obtain expression; it was, that is to say, unconscious. If we subsequently bring the intention to the speaker's notice, he may recognize it as a familiar one, in which case it was only temporarily unconscious, or he may repudiate it as foreign to him, in which case it was permanently unconscious. Such an observation as this justifies us in also regarding what we have called *latent* as something *unconscious*. The consideration of these dynamic relations puts us in a position to distinguish two kinds of unconscious: one which is transformed into conscious material easily and under conditions which frequently arise, and another in the case of which such a transformation is difficult, can only come about with a considerable expenditure of energy, or may never occur at all. In order to avoid any ambiguity as to whether we are referring to the one or the other unconscious, whether we are using the word in the descriptive or dynamic sense, we make use of a legitimate and simple expedient. We call the unconscious which is only latent, and so can easily become conscious, the *preconscious*, and keep the name *unconscious* for the other. We have now three terms, *conscious*, *preconscious*, and *unconscious*, to serve our purposes in describing mental phenomena. Once again, from a purely descriptive point of view, the *preconscious* is also unconscious, but we do not give

it that name, except when we are speaking loosely, or when we have to defend in general the existence of unconscious processes in mental life.

You will, I hope, grant that so far things are not so bad and that the scheme is a convenient one. That is all very well; unfortunately our psycho-analytic work has compelled us to use the word *unconscious* in yet another, third, sense; and this may very well have given rise to confusion. Psycho-analysis has impressed us very strongly with the new idea that large and important regions of the mind are normally removed from the knowledge of the ego, so that the processes which occur in them must be recognized as unconscious in the true dynamic sense of the term. We have consequently also attributed to the word *unconscious* a topographical or systematic meaning; we have talked of *systems* of the preconscious and of the unconscious, and of a conflict between the ego and the *Ucs* system; so that the word *unconscious* has more and more been made to mean a mental province rather than a quality which mental things have. At this point, the discovery, inconvenient at first sight, that parts of the ego and super-ego, too, are unconscious in the dynamic sense, has a facilitating effect and enables us to remove a complication. We evidently have no right to call that region of the mind which is neither ego or super-ego the *Ucs* system, since the character of unconsciousness is not exclusive to it. Very well; we will no longer use the word *unconscious* in the sense of a system, and to what we have hitherto called by that name we will give a better one, which will not give rise to misunderstandings. Borrowing, at G. Groddeck's suggestion, a term used by Nietzsche, we will call it henceforward the *id*. This impersonal pronoun seems particularly suited to express the essential character of this province of the mind—the character of being foreign to the ego. Super-ego, ego and *id*, then, are the three realms, regions or provinces into which we divide the mental apparatus of the individual; and it is their mutual relations with which we shall be concerned in what follows.

But before we go on I must make a short digression. I have no doubt that you are dissatisfied with the fact that the three qualities of the mind in respect to consciousness and the three regions of the mental apparatus do not fall together into three harmonious pairs, and that you feel that the clarity of our conclusions is consequently impaired. My own view is that

we ought not to deplore this fact but that we should say to ourselves that we had no right to expect any such neat arrangement. Let me give you an analogy; analogies prove nothing, that is quite true, but they can make one feel more at home. Let us picture a country with a great variety of geographical configurations, hills, plains and chains of lakes, and with mixed nationalities living in it, Germans, Magyars and Slovaks, who, moreover, are engaged upon a number of different occupations. Now the distribution might be such that the Germans lived in the hills and kept cattle, the Magyars on the plains and grew corn and vines, while the Slovaks lived by the lakes and caught fish and plaited reeds. If this distribution were neat and exact it would no doubt give great satisfaction to a President Wilson; it would also be convenient for giving a geography lesson. It is probable, however, that you would find a less orderly state of affairs if you visited the region. Germans, Magyars and Slovaks would be living everywhere mixed up together, and there would be cornfields, too, in the hills, and cattle would be kept on the plains as well. One or two things would be as you expected, for one cannot catch fish on the mountains, and wine does not grow in water. The picture of the region which you had brought with you might on the whole fit the facts, but in details you would have to put up with departures from it.

You must not expect me to tell you much that is new about the id, except its name. It is the obscure inaccessible part of our personality; the little we know about it we have learnt from the study of dream-work and the formation of neurotic symptoms, and most of that is of a negative character, and can only be described as being all that the ego is not. We can come nearer to the id with images, and call it a chaos, a cauldron of seething excitement. We suppose that it is somewhere in direct contact with somatic processes, and takes over from them instinctual needs and gives them mental expression, but we cannot say in what substratum this contact is made. These instincts fill it with energy, but it has no organization and no unified will, only an impulsion to obtain satisfaction for the instinctual needs, in accordance with the pleasure-principle. The laws of logic—above all, the law of contradiction—do not hold for processes in the id. Contradictory impulses exist side by side without neutralizing each other or drawing apart; at most they combine in compromise formations under the overpowering economic pressure towards dis-

charging their energy. There is nothing in the id which can be compared to negation, and we are astonished to find in it an exception to the philosophers' assertion that space and time are necessary forms of our mental acts. In the id there is nothing corresponding to the idea of time, no recognition of the passage of time, and (a thing which is very remarkable and awaits adequate attention in philosophic thought) no alteration of mental processes by the passage of time. Conative impulses which have never got beyond the id, and even impressions which have been pushed down into the id by repression, are virtually immortal and are preserved for whole decades as though they had only recently occurred. They can only be recognized as belonging to the past, deprived of their significance, and robbed of their charge of energy, after they have been made conscious by the work of analysis, and no small part of the therapeutic effect of analytic treatment rests upon this fact.

It is constantly being borne in upon me that we have made far too little use of our theory of the indubitable fact that the repressed remains unaltered by the passage of time. This seems to offer us the possibility of an approach to some really profound truths. But I myself have made no further progress here.

Naturally, the id knows no values, no good and evil, no morality. The economic, or, if you prefer, the quantitative factor, which is so closely bound up with the pleasure-principle, dominates all its processes. Instinctual cathexes seeking discharge—that, in our view, is all that the id contains. It seems, indeed, as if the energy of these instinctual impulses is in a different condition from that in which it is found in the other regions of the mind. It must be far more fluid and more capable of being discharged, for otherwise we should not have those displacements and condensations, which are so characteristic of the id and which are so completely independent of the qualities of what is cathected. (In the ego we should call it an *idea*.) What would one not give to understand these things better? You observe, in any case, that we can attribute to the id other characteristics than that of being unconscious, and you are aware of the possibility that parts of the ego and super-ego are unconscious without possessing the same primitive and irrational quality. As regards a characterization of the ego, in so far as it is to be distinguished from the id and the super-ego, we shall get on better if we turn our attention to the relation between

it and the most superficial portion of the mental apparatus; which we call the *Pcpt-Cs* (perceptual-conscious) system. This system is directed on to the external world, it mediates perceptions of it, and in it is generated, while it is functioning, the phenomenon of consciousness. It is the sense-organ of the whole apparatus, receptive, moreover, not only of excitations from without but also of such as proceed from the interior of the mind. One can hardly go wrong in regarding the ego as that part of the id which has been modified by its proximity to the external world and the influence that the latter has had on it, and which serves the purpose of receiving stimuli and protecting the organism from them, like the cortical layer with which a particle of living substance surrounds itself. This relation to the external world is decisive for the ego. The ego has taken over the task of representing the external world for the id, and so of saving it; for the id, blindly striving to gratify its instincts in complete disregard of the superior strength of outside forces, could not otherwise escape annihilation. In the fulfilment of this function, the ego has to observe the external world and preserve a true picture of it in the memory traces left by its perceptions, and, by means of the reality-test, it has to eliminate any element in this picture of the external world which is a contribution from internal sources of excitation. On behalf of the id, the ego controls the path of access to motility, but it interpolates between desire and action the procrastinating factor of thought, during which it makes use of the residues of experience stored up in memory. In this way it dethrones the pleasure-principle, which exerts undisputed sway over the processes in the id, and substitutes for it the reality-principle, which promises greater security and greater success.

The relation to time, too, which is so hard to describe, is communicated to the ego by the perceptual system; indeed it can hardly be doubted that the mode in which this system works is the source of the idea of time. What, however, especially marks the ego out in contrast to the id, is a tendency to synthesize its contents, to bring together and unify its mental processes which is entirely absent from the id. When we come to deal presently with the instincts in mental life, I hope we shall succeed in tracing this fundamental characteristic of the ego to its source. It is this alone that produces that high degree of organization which the ego needs for its

highest achievements. The ego advances from the function of perceiving instincts to that of controlling them, but the latter is only achieved through the mental representative of the instinct becoming subordinated to a larger organization, and finding its place in a coherent unity. In popular language, we may say that the ego stands for reason and circumspection, while the id stands for the untamed passions.

So far we have allowed ourselves to dwell on the enumeration of the merits and capabilities of the ego; it is time now to look at the other side of the picture. The ego is after all only a part of the id, a part purposively modified by its proximity to the dangers of reality. From a dynamic point of view, it is weak; it borrows its energy from the id, and we are not entirely ignorant of the methods—one might almost call them "tricks"—by means of which it draws further amounts of energy from the id. Such a method, for example, is the process of identification, whether the object is retained or given up. The object-cathexes proceed from the instinctual demands of the id. The first business of the ego is to take note of them. But by identifying itself with the object, it recommends itself to the id in the place of the object and seeks to attract the libido of the id on to itself. We have already seen that, in the course of a person's life, the ego takes into itself a large number of such precipitates of former object-cathexes. On the whole, the ego has to carry out the intentions of the id; it fulfils its duty if it succeeds in creating the conditions under which these intentions can best be fulfilled. One might compare the relation of the ego to the id with that between a rider and his horse. The horse provides the locomotive energy, and the rider has the prerogative of determining the goal and of guiding the movements of his powerful mount towards it. But all too often in the relations between the ego and the id we find a picture of the less ideal situation in which the rider is obliged to guide his horse in the direction in which it itself wants to go.

The ego has separated itself off from one part of the id by means of repression-resistances. But the barrier of repression does not extend into the id; so that the repressed material merges into the rest of the id.

The proverb tells us that one cannot serve two masters at once. The poor ego has a still harder time of it; it has to serve three harsh masters, and has to do its best to reconcile the claims and demands of all three. These de-

mands are always divergent and often seem quite incompatible; no wonder that the ego so frequently gives way under its task. The three tyrants are the external world, the super-ego, and the id. When one watches the efforts of the ego to satisfy them all, or rather, to obey them all simultaneously, one cannot regret having personified the ego, and established it as a separate being. It feels itself hemmed in on three sides and threatened by three kinds of danger, towards which it reacts by developing anxiety when it is too hard pressed. Having originated in the experiences of the perceptual system, it is designed to represent the demands of the external world, but it also wishes to be a loyal servant of the id, to remain upon good terms with the id, to recommend itself to the id as an object, and to draw the id's libido on to itself. In its attempt to mediate between the id and reality, it is often forced to clothe the *Ucs* commands of the id with its own *Pcs* rationalizations, to gloss over the conflicts between the id and reality, and with diplomatic dishonesty to display a pretended regard for reality, even when the id persists in being stubborn and uncompromising. On the other hand, its every movement is watched by the severe super-ego, which holds up certain norms of behaviour, without regard to any difficulties coming from the id and the external world; and if these norms are not acted up to, it punishes the ego with the feelings of tension which manifest themselves as a sense of inferiority and guilt. In this way, goaded on by the id, hemmed in by the super-ego, and rebuffed by reality, the ego struggles to cope with its economic task of reducing the forces and influences which work in it and upon it to some kind of harmony; and we may well understand how it is that we so often cannot repress the cry: "Life is not easy." When the ego is forced to acknowledge its weakness, it breaks out into anxiety: reality anxiety in face of the external world, normal anxiety in face of the super-ego, and neurotic anxiety in face of the strength of the passions in the id.

I have represented the structural relations within the mental personality, as I have explained them to you, in a simple diagram, which I here reproduce.

You will observe how the super-ego goes down into the id; as the heir to the Oedipus complex it has, after all, intimate connections with the id. It lies further from the perceptual system than the ego. The id only deals with the external world through the medium of the ego,

at least in this diagram. It is certainly still too early to say how far the drawing is correct; in one respect I know it is not. The space taken up by the unconscious id ought to be incomparably greater than that given to the ego or to the preconscious. You must, if you please, correct that in your imagination.

And now, in concluding this certainly rather exhausting and perhaps not very illuminating account, I must add a warning. When you think of this dividing up of the personality into ego, super-ego, and id, you must not imagine sharp dividing lines such as are artificially drawn in the field of political geography. We cannot do justice to the characteristics of the mind by means of linear contours, such as occur in a drawing or in a primitive painting, but we need rather the areas of colour shading off into one another that are to be found in modern pictures. After we have made our separations, we must allow what we have separated to merge again. Do not judge too harshly of a first attempt at picturing a thing so elusive as the human mind. It is very probable that the extent of these differentiations varies very greatly from person to person; it is possible that their function itself may vary, and that they may at times undergo a process of involution. This seems to be particularly true of the most insecure and, from the phylogenetic point of view, the most recent of them, the differentiation between the ego and the super-ego. It is also

incontestable that the same thing can come about as a result of mental disease. It can easily be imagined, too, that certain practices of mystics may succeed in upsetting the normal relations between the different regions of the mind, so that, for example, the perceptual system becomes able to grasp relations in the deeper layers of the ego and in the id which would otherwise be inaccessible to it. Whether

such a procedure can put one in possession of ultimate truths, from which all good will flow, may be safely doubted. All the same, we must admit that the therapeutic efforts of psycho-analysis have chosen much the same method of approach. For their object is to strengthen the ego, to make it more independent of the super-ego, to widen its field of vision, and so to extend its organization that it can take over new portions of the id. Where id was, there shall ego be.

It is reclamation work, like the draining of the Zuyder Zee.

## LECTURE 32

### ANXIETY AND INSTINCTUAL LIFE

LADIES AND GENTLEMEN: You will not be surprised to hear that I have a great deal of new information to give you about our hypotheses on the subject of anxiety and the fundamental instincts of the mind, and also that none of this information claims to provide a final solution of these doubtful problems. I speak purposely of *hypotheses*. This is the most difficult task that has been set us, but the difficulty does not lie in the incompleteness of our observations, for it is actually the commonest and most familiar phenomena that present us with such riddles; nor does it lie in the remoteness of the speculations to which these phenomena give rise, for speculation hardly comes into the picture in this connection. No, it is genuinely a question of hypotheses; that is to say, of the introduction of the right abstract ideas, and of their application to the raw material of observation so as to bring order and lucidity into it.

I devoted one lecture in my former series—the twenty-fifth—to the study of anxiety. I must recapitulate its contents in brief. We said then that anxiety is an affective condition—that is to say, a combination of certain feelings of the pleasure-pain series with their corresponding efferent innervations, and a perception of them—but we asserted that anxiety is probably also the trace of a certain important event, taken over by inheritance, and therefore comparable to the ontogenetically acquired hysterical attack. We suggested that the event which left this affective trace behind it was the process of birth, in which the modifications of the heart's action and of respiration, which are characteristic of anxiety, served a useful purpose. The first anxiety of all would thus have been a toxic one. We then started from the

distinction between objective anxiety and neurotic anxiety, the former being what seems to us an intelligible reaction to danger—that is, to anticipated injury from without—and the latter altogether puzzling and, as it were, purposeless. In our analysis of objective anxiety we explained it as a condition of increased sensory attention and motor tension, which we called *anxiety-preparedness*. Out of this the anxiety-reaction arises. The anxiety-reaction may run one of two courses. Either the *anxiety-development*, the repetition of the old traumatic experience, is restricted to a signal, in which case the rest of the reaction can adapt itself to the new situation of danger, whether by flight or defence; or the old experience gets the upper hand, and the whole reaction exhausts itself in anxiety-development, in which case the affective state is paralyzing and unadapted to the present situation.

We then turned our attention to neurotic anxiety, and pointed out that it could be observed in three forms. Firstly, we have free-floating, general apprehensiveness, ready to attach itself for the time being to any new possibility that may arise in the form of what we call *expectant dread*, as happens, for instance, in the typical anxiety-neurosis. Secondly, we find it firmly attached to certain ideas, in what are known as *phobias*, in which we can still recognize a connection with external danger, but cannot help regarding the anxiety felt towards it as enormously exaggerated. Thirdly and finally, we have anxiety as it occurs in hysteria and in other severe neuroses; this anxiety either accompanies symptoms or manifests itself independently, whether as an attack or as a condition which persists for some time, but always without having any visible justification in an external danger. We then asked ourselves two questions: "What are people afraid of when they have neurotic anxiety?" and: "How can one bring this kind of anxiety into line with objective anxiety felt towards an external danger?"

Our investigations were by no means unsuccessful, and we succeeded in reaching a few important conclusions. With regard to anxious expectation, clinical experience has taught us that there is a regular relationship between it and the disposition of the libido in the sexual life. The most frequent cause of anxiety-neurosis is undischarged excitation. A libidinal excitation is aroused, but is not satisfied or used; in the place of this libido which has been diverted from its use, anxiety makes its appear-

ance. I even thought it was justifiable to say that this unsatisfied libido is directly transformed into anxiety. This view found some support in certain almost universal phobias of small children. Many of these phobias are altogether enigmatic, but others, such as the fear of being left alone and the fear of unfamiliar people, can be definitely explained. Being left alone or seeing strange faces stirs up the child's longing for the familiar presence of its mother; it cannot control this libidinal excitation; it cannot keep it in a state of suspension, but turns it into anxiety. This anxiety in children, therefore, is not objective anxiety, but must be classed among the neurotic anxieties. Children's phobias, and the anxious expectation in anxiety-neurosis, serve as two examples of one way in which neurotic anxiety comes about; i.e., through direct transformation of libido. In a moment we shall learn of a second method, and we shall see that it is not so very different from the first.

For it is to the process of repression that we attribute the appearance of anxiety in hysteria and other neuroses. We now believe that it is possible to give a fuller description of this process than before, if we separate the history of the idea that has to be repressed from that of the libido which is attached to it. It is the idea that undergoes repression and may be distorted so as to become unrecognizable; its associated affect is always turned into anxiety, regardless of its nature, whether, that is to say, it is aggression or love. Now it makes no essential difference on what grounds a given quantity of libido has become unusable, whether on account of the infantile weakness of the ego, as in the case of children's phobias, or on account of somatic processes in sexual life, as in the case of anxiety neuroses, or on account of repression, as in the case of hysteria. The two mechanisms which give rise to neurotic anxiety are therefore essentially the same.

While we were engaged in these investigations, we noticed a very important connection between anxiety-development and symptom-formation. It was that the two are interchangeable. The agoraphobic, for example, begins his illness with an attack of anxiety in the street. This is repeated every time he walks along the street again. He now develops a symptom—a street phobia—which can also be described as an inhibition or a functional restriction of the ego; and thus he preserves himself from anxiety attacks. One can observe the reverse process if one interferes with the

formation of symptoms, as is possible, for instance, in the case of obsessive acts. If one prevents a patient from carrying out his washing ceremonial, he is thrown into an intolerable state of anxiety, against which his symptom has obviously protected him. And, indeed, it seems as though anxiety-development is the earlier and symptom-formation the later of the two, as though the symptom were created in order to prevent the outbreak of a state of anxiety. And it is in keeping with this that the first neuroses of childhood are phobias—conditions, that is to say, in which one sees quite clearly how what began as anxiety-development is later replaced by symptom-formation: one gets an impression that this circumstance affords the best starting-point from which to approach an understanding of neurotic anxiety. At the same time, we succeeded in discovering the answer to the question of what it is that one fears in neurotic anxiety, and thus restoring the connection between neurotic anxiety and objective anxiety. What one fears is obviously one's own libido. The difference between this and objective anxiety lies in two points—that the danger is an internal instead of an external one, and that it is not consciously recognized.

In the case of phobias one can see clearly how this internal danger is transformed into an external one; how, that is to say, neurotic anxiety turns into apparent objective anxiety. Let us simplify a state of affairs which is often very complicated, and suppose that the agoraphobic is always afraid of his impulses in connection with temptations aroused in him by meeting people in the street. In his phobia he makes a displacement and is now afraid of an external situation. What he gains thereby is obvious; it is that he feels he can protect himself better in that way. One can rescue oneself from an external danger by flight, whereas to attempt to fly from an internal danger is a difficult undertaking.

At the end of my original lecture on anxiety I expressed the opinion that, though these various results of our investigations did not actually contradict one another, they were nevertheless not entirely consistent. As an affective condition, anxiety is the reproduction of an old danger-threatening event; anxiety serves the purposes of self-preservation as being a signal of the presence of a new danger; it arises from libido that has become unusable for some reason or other, including the process of repression; it is replaced by symptom-formation, and is thus, as it were, psychically

bound; in all of this one feels that something is missing which would combine these fragments into a unity.

Ladies and Gentlemen—The division of the mental personality into a super-ego, ego, and id, which I spoke about in the last lecture, has forced us to take up a new position with regard to the problem of anxiety. In assuming that the ego is the only seat of anxiety, and that only the ego can produce and feel anxiety, we have taken up a new and secure position, from which many facts take on a new aspect. And when you come to think of it, it is difficult to see what sense there could be in speaking of an *anxiety of the id*, or how we could ascribe a capacity for feeling anxiety to the super-ego. On the contrary, we have found a satisfactory confirmation of our theory in the fact that the three main varieties of anxiety—objective anxiety, neurotic anxiety, and moral anxiety—can so easily be related to the three directions in which the ego is dependent, on the external world, on the id, and on the super-ego. Our new position, too, has brought to the fore the function of anxiety as a signal indicating the presence of a danger-situation, a function with which we were already not unfamiliar. The question of the stuff out of which anxiety is made loses interest for us, and the relations between objective anxiety and neurotic anxiety are clarified and simplified in a surprising way. And, besides this, it is to be noticed that we now understand the apparently complicated cases of anxiety-formation better than we do those which seem to be simple.

We have recently investigated the manner in which anxiety comes about in certain phobias, which we class with anxiety-hysteria, and we have chosen for investigation cases in which we have to deal with the typical repression of desires proceeding from the Oedipus complex. We should have expected to find that it is the libidinal cathexis of the mother as object which, as a result of repression, is transformed into anxiety, and now manifests itself in the form of a symptom as attached to the father-substitute. I cannot tell you all the individual steps of an investigation of this kind; let it suffice to say that, to our astonishment, the result was the reverse of what we had expected. It is not the repression that creates the anxiety, but the anxiety is there first and creates the repression! But what sort of anxiety can it be? It can only be fear of a threatening external danger, that is to say, objective anxiety. It is true that the boy is afraid of the demands of his libido, in

this case of his love for his mother; so that this is really an instance of neurotic anxiety. But this being in love seems to him to be an internal danger, which he must avoid by renouncing his object, only because it involves an external danger-situation. And in every case we have investigated we have obtained the same result. It must, however, be confessed that we were not prepared to find that the instinctual danger was only a half-way house to an external and real danger-situation.

We have, however, not yet said what the real danger is that the child fears as a result of his being in love with his mother. It is the punishment of castration, the loss of his penis. Naturally, you will object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus-complex. But the question cannot be so easily dismissed. It is not primarily a matter of whether castration is really performed; what is important is that the danger is one that threatens from without, and that the boy believes in it. He has some grounds for doing so, for, not infrequently, threats of his penis being cut off are made during his phallic phase, at the time of his early masturbation; and no doubt allusions to such a punishment will always find a phylogenetic reinforcement on his side. We have conjectured that, in the early days of the human family, castration really was performed on the growing boy by the jealous and cruel father, and that circumcision, which is so frequently an element in puberty rites, is an easily recognizable trace of it. We are aware of how far removed we are from the common point of view in saying this, but we must maintain our position that fear of castration is one of the most frequent and one of the strongest motive forces of repression, and therefore of the formation of neuroses. The analysis of cases in which, it is true, not castration itself, but circumcision, has been performed on boys as a cure or as a punishment for masturbation (a thing which was by no means of rare occurrence in English and American society) has provided us with conclusive proof that we are right. It is a great temptation at this juncture to go further into the castration-complex, but we will keep to our subject. Fear of castration is naturally not the only motive for repression; to start with, it has no place in the psychology of women; they have, of course, a castration-complex, but they cannot have any fear of castration. In its place, for the other sex, is

found fear of the loss of love, obviously a continuation of the fear of the infant at the breast when it misses its mother. You will understand what objective danger-situation is indicated by this kind of anxiety. If the mother is absent or has withdrawn her love from the child, it can no longer be certain that its needs will be satisfied, and may be exposed to the most painful feelings of tension. There is no need to reject the idea that these conditions for anxiety fundamentally repeat the situation of the original birth-anxiety, which, to be sure, also implied separation from the mother. Indeed, if you follow a line of thought suggested by Ferenczi, you may add fear of castration, too, to this series, for the loss of the male genital organ results in the impossibility of a reunion with the mother, or with a substitute for her, in the sexual act. I might mention, incidentally, that the common phantasy of returning into the womb is a substitute for this desire for coitus. There are still a great number of interesting and surprising facts which I might tell you about in this connection; but I must not step beyond the bounds of an introduction to psycho-analysis. I will, therefore, merely draw your attention to the way in which, at this point, the findings of psychology take us to the frontiers of biological fact.

Otto Rank, to whom psycho-analysis owes many valuable contributions, has also the merit of having strongly emphasized the importance of the act of birth and of separation from the mother. It is true that the rest of us found it impossible to accept the extreme deductions that he drew from this factor with regard to the theory of the neuroses and even to analytical therapy. But before this he had already discovered the central feature of his doctrine, namely, that the anxiety-experience of birth is the prototype of all later danger-situations. If we pause for a moment at this point we can say that, as a matter of fact, every stage of development has its own particular conditions for anxiety; that is to say, a danger-situation appropriate to it. The danger of mental helplessness corresponds to the stage of early immaturity of the ego; the danger of loss of object or of love corresponds to the dependence of the early years of childhood; the danger of castration to the phallic phase; and finally, the fear of the super-ego, which occupies a special position, to the period of latency. As development proceeds, the old conditions for anxiety should vanish, since the danger-situations, which correspond to them, have lost their force

owing to the strengthening of the ego. But this only happens to a very incomplete degree. A great many people cannot overcome the fear of loss of love; they never become independent enough of the love of other people, and continue their infantile behaviour in this respect. The fear of the super-ego should normally never cease, since it is indispensable in social relations in the form of moral anxiety, and it is only in the rarest instances that an individual succeeds in becoming independent of the community. A few of the old danger-situations also manage to preserve their force in later life by giving their conditions for anxiety an up-to-date form. Thus, for instance, the danger of castration is preserved under the disguise of syphilidophobia. Grown-up people are well aware that castration is no longer practised as a punishment for indulging sexual desires, but, on the other hand, they have learned from experience that instinctual freedom in this direction involves the risk of severe illnesses. There is no doubt that persons whom we call *neurotic* remain infantile in their attitude towards danger and have not grown out of antiquated conditions for anxiety. Let us accept this as a factual contribution to our characterization of neurotics; why it should be so is not so easy to say.

I hope you have not lost the thread of our discourse, and that you remember that we are discussing the relations between anxiety and repression. We have discovered two new facts in doing so: first, that anxiety causes repression, and not the other way round as we used to think, and secondly, that frightening *instinctual* situations can in the last resort be traced back to *external* situations of danger. Our next question will be: How can we picture the process of repression carried out under the influence of anxiety? I think this is what happens: the ego becomes aware that the satisfaction of some nascent instinctual demand would evoke one among the well-remembered danger-situations. This instinctual cathexis must, therefore, somehow or other be suppressed, removed, made powerless. We know that the ego succeeds in this task if it is strong, and if it has assimilated the impulse in question into its organization. In the case of repression, however, the impulse is still a part of the id, and the ego feels weak. In such a contingency, the ego calls to its aid a technique, which is, at bottom, identical with that of normal thinking. Thinking is an experimental dealing with small quantities of energy, just as a general moves miniature

figures about over a map before setting his troops in motion. In this way, the ego anticipates the satisfaction of the questionable impulse, and enables it to reproduce the painful feelings which are attached to the beginning of the dreaded danger-situation. Thereupon the automatic mechanism of the pleasure-pain principle is brought into play and carries through the repression of the dangerous impulse.

"Stop!" you will exclaim, "we cannot go so far as that with you." You are right; I shall have to add something to what I have said, to make it seem acceptable to you. First of all, I must admit that I have tried to translate into the language of our normal thought a process which is in fact certainly neither conscious nor preconscious, and which takes place between charges of energy at some deep level of the mind that it is hard to picture. But that is not a very serious objection; it could not be done in any other way. It is more important that we should clearly distinguish between what goes on in the ego and what goes on in the id during the process of repression. We have just explained what the ego does. It makes use of an experimental cathexis, and by means of a danger-signal sets in motion the automatic pleasure-pain mechanism. Several reactions then become possible, or a combination of them, in various proportions. Either the anxiety attack develops completely and the ego withdraws entirely from the objectionable excitation; or, in place of the experimental cathexis, the ego meets the excitation with an anti-cathexis (counter-charge) which then combines with the energy of the repressed impulse to form a symptom, or is taken up into the ego as a reaction-formation, as an intensification of certain dispositions, as a permanent alteration of the ego. The more the development of anxiety can be restricted to a mere signal, the more the ego can make use of defensive acts, which amount to a mental binding of the repressed, and the more the process approximates to the standard of a normal modification of the impulse, without of course ever reaching it. Here I shall digress for a moment or so. You will, no doubt, yourselves have assumed that the thing which is so hard to define but which we call *character* must be thought of as belonging entirely to the province of the ego. We have already learned something of what it is that creates this thing called character. The incorporation of the early parental function in the shape of the super-ego is no doubt the most important and decisive element; next come identifications with the par-

ents of a later date and with other persons in authority, and the same identifications as precipitates of abandoned object-relations. We can now add to this list, as contributions to character-formation which are never absent, the reaction-formations which the ego acquires, first in making its repressions, and later in a more normal way, in repudiating undesirable impulses.

Now let us go back to a consideration of the id. It is not so easy to discover what it is that happens during the process of repression to the impulses that are being opposed. The main question to which we want to know the answer is: What happens to the energy, to the libidinal charge of the impulse, and how is it used? You will remember that my earlier hypothesis was that it was precisely this energy that was turned into anxiety. We can, however, no longer venture to say that; we must content ourselves with a more modest answer. Its fate is probably not always the same. Probably there is a close correspondence between what happens in the ego and what happens in the id with respect to the repressed impulse, and it should be possible to learn something of its nature. For, since we have adopted the view that the pleasure-pain principle is brought into action in response to the danger-signal, and plays a part in repression, we are obliged to modify our anticipations. This principle has unrestricted sway over the processes in the id. We can credit it, too, with the power of bringing about very profound changes in the impulse in question. We are, therefore, prepared to believe that the effects of repression will be very varied, and sometimes more and sometimes less extensive. In many cases the repressed impulse may retain its libidinal cathexis, and continue to exist unaltered in the id, although under the perpetual pressure of the ego. In other instances it seems to undergo complete destruction, in which case its libido is finally diverted into other channels. I have suggested that this is what happens where the Oedipus complex is dealt with normally. In this desirable state of affairs, the Oedipus complex would thus not merely be repressed, but would be actually destroyed in the id. Clinical experience has further taught us that in a great many cases, instead of the usual result of repression, a degradation of the libido take place, a regression of the libidinal organization to an earlier stage of development. That can naturally only happen in the id, and when it does happen, it must be under the influence of the same conflict that

was introduced by the danger-signal. The most remarkable example of this is to be found in the obsessional neurosis, where regression of libido and repression go hand in hand.

Ladies and Gentlemen—I am afraid that this account will seem to you very difficult to follow, and you will guess that it is by no means a complete one. I am sorry to have caused you annoyance. My only aim, however, must be to give you some impression of the nature of our findings, and of the difficulties we have to face in dealing with them. The deeper we probe in our study of mental processes, the more we become aware of the richness and complexity of their content. Many simple formulas which seemed to us at first to meet the case, turned out later to be inadequate. We are incessantly altering and improving them. In my lecture on the theory of dreams, I led you into a field of knowledge in which hardly a single new discovery has been made in the last fifteen years; here, where we are dealing with anxiety, everything is in a state of flux and change. These new findings have not yet been thoroughly worked over, and perhaps for that very reason their exposition is difficult. However, you must have patience; we shall soon be able to leave the problem of anxiety, though that does not mean that it will have been solved to our satisfaction. I hope, however, that we have advanced a step further. And incidentally we have acquired much fresh knowledge. Thus we are now able, through the study of anxiety, to add a fresh trait to our characterization of the ego. We have said that the ego is weak in relation to the id, that it is its faithful servant, and that it tries to carry out its orders and fulfil its requirements. We have no intention of withdrawing this assertion. But on the other hand the ego is the better organized part of the id, orientated as it is towards reality. We must not exaggerate too much the separation between the two, and we must not be surprised if the ego, too, on its side exerts an influence on the processes in the id. I think the ego exerts an influence of this kind when it sets the all-powerful pleasure-pain principle in motion by means of the danger-signal. It is true that immediately afterwards it displays its weakness again, for by the act of repression it renounces a portion of its organization, and is obliged to allow the repressed impulse to remain permanently withdrawn from its influence.

And now just one more point in regard to the problem of anxiety. Neurotic anxiety has, under our hands, turned into objective anxiety,

into anxiety felt towards certain external danger-situations. But we cannot leave it at that; we must take a step further, though in a sense it will be a step backwards. What is it that is actually dangerous and actually feared in such a danger-situation? It is clearly not the objective injury, which need have absolutely no importance psychologically, but it is something which is set up in the mind by it. Birth, for example, our prototype for the state of anxiety, can hardly in itself be regarded as an injury, although it may involve a risk of injury. The fundamental thing about birth, as about every danger-situation, is that it evokes in mental experience a condition of tense excitation, which is felt as pain, and which cannot be mastered by discharge. Let us call such a situation, in which the efforts of the pleasure-principle come to nothing, a *traumatic* factor; in that way, by following the series—neurotic anxiety-objective anxiety-danger-situation—we can arrive at a simple formula: what is feared, the object of the anxiety, is always the emergence of a traumatic factor, which cannot be dealt with in accordance with the norms of the pleasure-principle. We can immediately see that the operation of the pleasure-principle does not guarantee us against objective injury, but only against a particular injury to our mental economy. From the pleasure-principle to the instinct of self-preservation is a long way; and the two tendencies are far from coinciding from the first. We can observe something else, however, and perhaps this is the solution for which we were looking. I have in mind the fact that all along we are dealing with questions of relative quantities. It is only the magnitude of the excitation which turns an impression into a traumatic factor, which paralyzes the operation of the pleasure-principle and gives significance to the danger-situation. And if this is really the case, if these problems admit of such a simple solution, why should it not be possible that traumatic factors of this kind should occur in the mental life without relation to the supposed danger-situations, traumatic factors in regard to which anxiety is not aroused as a signal, but manifests itself afresh and for new reasons? Clinical experience definitely tells us that this actually occurs. Only the later repressions display the mechanism which we have described, in which anxiety is called forth as a signal of an earlier danger-situation; the earliest and most fundamental repressions arise directly from traumatic factors, where the ego comes into contact with an excessive libidinal

demand; these traumatic factors create their own anxiety anew, though in accordance with the pattern of the birth-situation. The same may be true of the development of anxiety in anxiety-neuroses, caused by somatic injury of the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to postulating twofold origin of anxiety, first as the direct effect of a traumatic factor, and secondly, as a signal that a traumatic factor of this kind threatens to recur.

Ladies and Gentlemen—I am sure you are delighted with the prospect of hearing no more about anxiety. But your delight will be short-lived, for what is to follow is no better. I propose to take you straight on to the subject of the theory of the libido or of the instincts, for there, too, many new developments have occurred. I cannot say that we have made any very great progress or that any trouble you may take in learning about it will be amply rewarded. No; it is a field in which we are struggling hard to get some sort of orientation and understanding; you will only be witnesses of the efforts we are making. Here, too, I shall have to repeat much that I put before you in my earlier lectures.

The theory of the instincts is, as it were, our mythology. The instincts are mythical beings, superb in their indefiniteness. In our work we cannot for a moment overlook them, and yet we are never certain that we are seeing them clearly. You know how popular thought deals with the instincts. It postulates as many different instincts as may be needed, an instinct of assertiveness, instincts of imitation and play, a social instinct and a great many more besides. It takes them up, as it were, lets each do its particular work, and then drops them again. We have always suspected that behind this multitude of small occasional instincts there lies something much more serious and powerful, which must be approached with circumspection. Our first step was tentative enough. We felt we should probably not go far wrong if we started by distinguishing two main instincts, or species or groups of instincts, corresponding to our two great needs—hunger and love. However jealously we may in other connections have defended the independence of psychology from all other sciences, nevertheless we are here overshadowed by the immutable biological fact that the living individual serves two purposes, self-preservation and the preservation of the species, which seem to be

independent of each other, which we have not been able to trace back to a common source, and whose interests often conflict in animal life. Here we are really discussing biological psychology, we are studying the psychological concomitants of biological processes. In accordance with this view, we introduced the *ego-instincts* and the *sexual instincts* into psychoanalysis. Under the former heading we placed everything that had to do with the preservation, maintenance and advancement of the individual. To the latter we ascribed the rich content implied in infantile and perverse sexual life. Our investigation of the neuroses led us to regard the ego as the restricting and repressing force and the sexual impulses as the restricted and repressed ones, with the result that we thought we had firmly grasped not only the difference between the two groups of instincts, but the conflict between them. At first, the objects of our studies consisted only of the sexual impulses, whose energy we called the *libido*. From the study of them we tried to make out what an instinct was and what attributes it possessed. At this point we reach the theory of the libido.

An instinct differs from a stimulus in that it arises from sources of stimulation within the body, operates as a constant force, and is such that the subject cannot escape from it by flight as he can from an external stimulus. An instinct may be described as having a source, an object, and an aim. The source is a state of excitation within the body, and its aim is to remove that excitation; in the course of its path from its source to the attainment of its aim the instinct becomes operative mentally. We picture it as a certain sum of energy forcing its way in a certain direction. We speak of active and passive instincts, but we ought rather to speak of active and passive instinctual aims; for an expenditure of activity is required even in order to attain a passive aim. The aim can be attained in the subject's own body, but as a rule an external object is introduced, in which the instinct attains its external aim; its internal aim is always a somatic modification which is experienced as satisfaction. Whether the relation to a somatic source gives the instinct any specific characters, and if so which, is not at all clear. The evidence of analytic experience proves conclusively that instinctual impulses from one source can join on to instinctual impulses from another and share their further vicissitudes, and that in general the satisfaction of one instinct can be substituted

for the satisfaction of another. It must be freely admitted, however, that we are not very clear about the explanation of this. The relations of an instinct to its aim and to its object are also susceptible to alterations; both can be exchanged for others, but the relation to the object is the more easily loosened of the two. There is a particular kind of modification of aim and change of object, with regard to which our social values come into the picture; to this we give the name of *sublimation*. We have also grounds for the differentiation of what we call *aim-inhibited* instincts; these proceed from familiar sources and have unambiguous aims, but come to a stop on their way to satisfaction, with the result that a permanent object-cathexis and an enduring driving force come into being. Of such a kind, for instance, is the feeling of affection, whose source undoubtedly lies in sexual needs but invariably renounces their gratification. We are, as you see, still in ignorance about many of the characteristics of the instincts and their history. We ought here to mention another distinction between the sexual instincts and the instincts of self-preservation which would be of the utmost theoretical importance, if it applied to the whole group. The sexual instincts are remarkable for their plasticity, for the facility with which they can change their aims, for their interchangeability—for the ease with which they can substitute one form of gratification for another, and for the way in which they can be held in suspense, as has been so well illustrated by the aim-inhibited instincts. It would be convenient if we could assert that these characteristics do not apply to the instincts of self-preservation, and that the latter are inflexible, do not allow of delay, are far more imperative and respond quite differently to repression and anxiety. On reflection, however, we see that this peculiarity does not apply to all the ego-instincts but only to those of hunger and thirst, and is clearly due to the special nature of their instinctual sources. A great deal of our perplexity also arises from the fact that we have not devoted any attention to the alterations which the instinctual impulses originally belonging to the id undergo under the influence of the organized ego.

We find ourselves on firmer ground when we turn to the question of how the instinctual life serves the sexual function. Here we have obtained decisive information; but you are already familiar with it. We do not, that is to say, believe that there is a single sexual in-

stinct, which is from the first the vehicle of the impulse towards the aim of the sexual function, that is, the union of the two sex cells. On the contrary, we see a large number of component instincts, arising from various regions of the body, which strive for satisfaction more or less independently of one another, and find this satisfaction in something that may be called *organ-pleasure*. The genitals are the latest of these *erotogenic zones*; and their organ-pleasure must certainly be called *sexual*. Not all of these pleasure-seeking impulses are incorporated in the final organization of the sexual function. Many of them are put aside as useless, by means of repression or in some other way; some of them are deflected from their aims in the remarkable manner which we have already mentioned and used for the strengthening of other impulses; while others persist, but play minor parts, and serve the purpose of bringing about preliminary actions and of arousing fore-pleasure. You have heard that in this long-drawn-out course of development several phases of provisional organization are to be recognized, and that aberrations and maldevelopments of the sexual function are to be explained by reference to its history. The first of these *pregenital* phases is called the *oral* phase, because, in accordance with the fact that the infant is nourished through the mouth, the erotogenic zone of the mouth dominates what we may call the sexual activity of this period of life. At a second stage the *sadistic* and *anal* impulses come to the fore, obviously in connection with the cutting of the teeth, the strengthening of the musculature, and the control of the sphincters. We have learnt a great many interesting details about this remarkable stage of development in particular. Third comes the *phallic* phase, in which for both sexes the penis (and what corresponds to it in the girl) achieves an importance which can no longer be overlooked. We have reserved the name of *genital* phase for the final sexual organization, established after puberty, in which the female genitals receive for the first time the recognition which the male genitals have long since obtained.

So far all this has been mere recapitulation. And you must not suppose that the things which I have omitted to mention this time no longer hold true. This recapitulation was necessary so that we could have a starting-point for our account of the further advance in our knowledge. We can flatter ourselves that we have obtained a great deal of new information

precisely about this matter of the early organizations of the libido and that we have a better understanding of what we already knew—in proof of which I will give you a few instances. In 1924, Abraham showed that we can differentiate two stages in the sadistic-anal phase. In the former of these the destructive tendencies to annihilate and to get rid of things have the upper hand, while in the latter those tendencies predominate which are friendly to the object, and seek to possess things and hold them fast. In the middle of this phase, then, there appears for the first time a consideration for the object which is a forerunner of a later relation of love towards the object. We are equally justified in assuming a similar subdivision in the first or oral phase. In the earlier stage of it, we only have oral incorporation, and there is no ambivalence in the relation to the object, i.e., the mother's breast. The second stage, which is distinguished by the onset of biting activities, may be called the *oral-sadistic* stage. It is here that we get the first manifestations of ambivalence, which become so much more obvious in the next, or sadistic-anal phase. The value of these new differentiations becomes especially clear when we want to discover the predispositional points of the libidinal development in the case of certain neuroses—such as obsessional neurosis and melancholia. I need only recall to you here what we have learnt on the subject of fixation of libido, predisposition, and regression.

Our attitude to the phases of libidinal organization has in general altered somewhat. We used formerly to emphasize the way in which one phase gives place to the next; nowadays, we direct our attention more to the facts which indicate how much of each earlier phase persists side by side with, and behind, later organizations, and obtains permanent representation in the economy of the libido and in the character of the individual. Even more important are those investigations which have shown us how frequently under pathological conditions regression to earlier phases takes place, and that certain regressions are characteristic of certain forms of illness. I cannot, however, go into that question here; it is a matter for a specialized treatise on the psychology of the neuroses.

We have been able to study the transformation of instincts and similar processes, especially with reference to anal-erotism, in which the impulses have their source in the erotogenic anal zone, and we are surprised to find the multiplicity of the channels along which these

instinctual impulses can be directed. It is, perhaps, not easy to free oneself from the contemptuous attitude which we have come to adopt towards this particular zone during the course of our development. It is as well, therefore, to bear in mind Abraham's reminder that embryologically the anus corresponds to the primitive mouth, which has moved down to the end of the bowel. It appears, then, that when, in the course of development, the individual comes to feel disfavour for his own faeces or excrement, his instinctual interest arising from anal sources passes over to objects which can be given away as gifts. And rightly so, for faeces were the first gift that the infant could make, and he parted with them out of love for the person who looked after him. Subsequently, the old interest in faeces turns into an appreciation of gold and money, and also makes a contribution to the affective cathexis attaching to the ideas of child and penis. It is the view of all children, who, as we know, cling to the cloaca-theory for a long time, that babies are born out of the bowel, like a piece of faeces; defecation is the prototype of the act of birth. But the penis, too, has its forerunner in the column of faeces, which fills the mucous membrane tube of the bowel and stimulates it. When the child has unwillingly imbibed the knowledge that there are human beings who do not possess a penis, that organ seems to him something which can be detached from the body, and an unmistakable analogy is drawn between it and the excrement which was the first piece of bodily substance that had to be given up. A large quantity of anal-erotism is thus transferred to the cathexis of the penis. But the interest in that part of the body has, besides an anal-erotic basis, a perhaps even more powerful root in oral erotism; for in accordance with the situation of sucking, the penis derives a great deal from the nipple of the mother's breast.

It is impossible to have any understanding of people's phantasies, or of associations which occur under the influence of the unconscious, or of the language of symptoms, if one does not know about these deep-lying connections. On this level, faeces-money-gift-child-penis are taken as having the same meaning, and can be represented by the same symbols. You must not forget that I can only give you very incomplete information on the subject. I will, however, add in passing that the late awakening interest in the vagina is mainly of anal-erotic derivation. This is not to be wondered at, since

the vagina is, in the admirable phrase of Lou Andreas-Salomé, "hired out" from the rectum; and in the lives of homosexuals, who have not got beyond a certain stage in their sexual development, the vagina is once more represented by the anus. In dreams we often meet with a place which was formerly a single room, but is now divided into two by a partition wall, or vice versa. This always refers to the relation of the vagina to the rectum. We can also follow very clearly the way in which in a girl, the entirely unfeminine desire for the possession of a penis normally turns into the desire for a child, and then for a man as the bearer of the penis and the giver of the child, so that in this case, too, we can see how an element of what was originally an anal-erotic interest is taken up into the later genital organization.

In the course of these studies of the pregenital phases of the libido, we have gleaned some new pieces of information about the formation of character. We have been made aware of a triad of characteristics which are almost always to be found together: orderliness, parsimoniousness, and obstinacy, and we have concluded from the analysis of persons possessing them that these characteristics proceed from the dissipation of their anal-erotism and its employment in other ways. Where this remarkable combination is to be found, therefore, we speak of an *anal character*, and in a sense contrast it with unmodified anal-erotism. A similar and perhaps even firmer connection is to be found between ambition and urethral erotism. We have found a remarkable reference to this correlation in the legend that Alexander the Great was born on the same night that a certain Herostratus, from a craving for notoriety, set fire to the famous temple of Artemis at Ephesus. It seems that the ancients were well aware of the connection involved. You already know how close a connection there is between urination and fire and the putting out of fire. Naturally, we expect to find that other traits of character will also turn out to be derived from pregenital libidinal formations, either as precipitates or as reaction-formations; but we cannot as yet demonstrate this.

It is now time for me to turn back to an earlier stage of our problem, and again take up the question of instinctual life in its most general aspect. The contrast between ego-instincts and sexual instincts lay, to begin with, at the bottom of our theory of the libido. When, later on, we began to study the ego in greater detail, and came to understand the idea of narcissism,

this distinction itself lost its validity. In certain rare cases one observes that the ego takes itself as object, and behaves as if it were in love with itself. For this reason we have borrowed the name of *narcissism* from the Greek legend. But that is only an extreme exaggeration of the normal course of events. We must understand that the ego is always the main reservoir of libido, from which libidinal cathexes of objects proceed, and into which they return again, while the greater part of this libido remains perpetually in the ego. There is therefore a constant transformation of ego-libido into object-libido, and of object-libido into ego-libido. But if this is so, the two cannot differ from each other in their nature, and there is no point in distinguishing the energy of the one from that of the other; one can either drop the term *libido* altogether, or use it as meaning the same as psychic energy in general.

We did not keep to this point of view for long. The idea of contrasting forces within the instinctual life was soon given another and more precise meaning. I shall not go through the processes by which I arrived at this new point of view; it, too, rests essentially on biological considerations; I will put it before you as a finished article. We suppose that there are two fundamentally different kinds of instincts, the sexual instincts in the widest sense of the word (*Eros*, if you prefer that name) and the aggressive instincts, whose aim is destruction. When it is put like that, you will hardly think of it as anything new; it looks as though it were a theoretical glorification of the commonplace opposition between love and hate, which may perhaps coincide with the polarity of attraction and repulsion which physics postulates for the inorganic world. But it is remarkable that this hypothesis was nevertheless felt by many to be an innovation, and indeed a most undesirable one which ought to be got rid of as soon as possible. I think a strong emotional factor was responsible for this rejection. Why have we ourselves taken so long to bring ourselves to recognize the existence of an aggressive instinct? Why was there so much hesitation in using for our theory facts which lay ready to hand and were familiar to every one? One would probably meet with but little opposition if one were to ascribe to animals an instinct with such an aim as this. But to introduce it into the human constitution seems impious; it contradicts too many religious prejudices and social conventions. No, man must be by nature good, or at least good-natured. If he

occasionally shows himself to be brutal, violent, and cruel, these are only passing disturbances of his emotional life, mostly provoked, and perhaps only the consequence of the ill-adapted social system which he has so far made for himself.

Unfortunately the testimony of history and our own experience do not bear this out, but rather confirm the judgment that the belief in the *goodness* of man's nature is one of those unfortunate illusions from which mankind expects some kind of beautifying or amelioration of their lot, but which in reality bring only disaster. We need not proceed with this polemic; for it is not on account of the teaching of history and of our own experience of life that we maintain the hypothesis of a special instinct of aggression and destructiveness in man, but on account of general considerations, to which we were led in trying to estimate the importance of the phenomena of *sadism* and *masochism*. You know that we use the word *sadism* when sexual satisfaction depends upon the sexual object suffering pain, ill-treatment, and humiliation, and the word *masochism*, when the subject himself has to suffer such treatment. You know, too, that there is a certain admixture of these two tendencies in normal sexual relations, and that we call them *perversions* when they thrust the other sexual aims into the background and substitute their own aims for them. It can hardly have escaped you that sadism has a close connection with masculinity, and masochism with femininity, as if there were some secret relationship between them. I must tell you at once that we have made no further progress along this path. Both of them, sadism and masochism, are very hard to account for by the theory of the libido, and especially masochism; and it is only right and proper that the stone which was an obstacle to the one theory should become the cornerstone of the other.

For we believe that in sadism and masochism we have two admirable examples of the fusion of the two kinds of instincts, Eros and aggressiveness, and we now put forward the hypothesis that this relationship is typical and that all the instinctual impulses that we can study are made up of such fusions or alloys of the two kinds of instincts. Naturally, they are to be found mixed in the greatest variety of proportions. To this mixture the erotic instincts will contribute the whole multiplicity of their sexual aims, while the others will admit only of mitigation and graduation of their uniform

tendency. This hypothesis opens up a line of investigation which may some day be of great importance for the understanding of pathological processes. For fusions may be undone, and such defusions of instincts may be expected to bring about the most serious consequences to adequate functioning. But this point of view is still too new; no one has so far attempted to make practical use of it.

Let us return to the specific problem which is presented by masochism. If we put its erotic components on one side for a moment, it proves the existence of a tendency which has self-destruction as its aim. We have already stated that the ego (or rather, as we should here say, the id, the whole personality) originally includes all the instinctual impulses; if this applies equally to the destructive instinct, it will follow that masochism is older than sadism; and that sadism is the destructive instinct directed outwards, thereby acquiring the character of aggressiveness. Varying quantities of the original destructive instinct may still remain inside the organism; it seems as though we could only perceive it under two conditions, either when it is bound up with the erotic instincts so as to form masochism, or when it is turned on to the external world (with a greater or lesser erotic addition) in the shape of aggressiveness. We are now led to consider the important possibility of the aggression being unable to find satisfaction in the external world, because it comes up against objective hindrances. It may then perhaps turn back and increase the amount of self-destructiveness within. We shall see that this actually occurs, and that it is an event of great importance. It would seem that aggression when it is impeded entails serious injury, and that we have to destroy other things and other people, in order not to destroy ourselves, in order to protect ourselves from the tendency to self-destruction. A sad disclosure, it will be agreed, for the moralist.

But the moralist will, for a long time to come, console himself with the improbability of our speculations. It is indeed a strange instinct that is occupied with the destruction of its own organic home! It is true that the poets speak of things of this sort; but poets are irresponsible beings, they enjoy the privilege of poetic licence. But, after all, such ideas are not foreign to physiology, where we find, for instance, the mucous membrane of the stomach digesting itself. But it must be admitted that our instinct of self-destruction requires more con-

firmation. One cannot put forward a hypothesis that is so far-reaching, simply on the ground that a few poor fools have attached a curious condition to their sexual satisfaction. I think that a deeper study of the instincts will give us what we want. The instincts do not only dominate mental life, but vegetative life as well, and these organic instincts display a characteristic which merits our most serious attention. Whether it is a general characteristic of all instincts we shall only be able to decide later. They turn out to be directed towards the reinstatement of an earlier state of things. We may assume that, as soon as a given state of things is upset, there arises an instinct to recreate it, and phenomena appear which we may call *repetition-compulsion*. Embryology, for instance, is nothing but a repetition-compulsion; stretching far back in the animal series we find a capacity to form afresh organs which have been lost, and the instinct of recovery, to which, alongside of our therapeutic activities, we owe our power to get well, may be the remains of this capacity which is so wonderfully developed in the lower animals. The spawning migrations of fish and perhaps the migrations of birds, possibly all that we describe as a manifestation of *instinct* in animals, takes place under the domination of repetition-compulsion, which expresses the *conservative nature* of instincts. And in the realm of the mind, too, we shall not have far to seek for evidence of the presence of that compulsion. It has always surprised us that the forgotten and repressed experiences of early childhood should reproduce themselves in dreams and reactions during analytic treatment, especially in the reactions involved in the transference, although their reawakening runs counter to the interests of the pleasure-principle; and we have explained this by saying that in such cases repetition-compulsion has overcome even the pleasure-principle. Outside analysis, too, one can observe the same thing. There are people who, all their lives, repeat, to their own detriment, the same reactions, without any correction, or who seem to be dogged by a relentless ill-fortune, though a closer investigation shows that they are unwittingly bringing this ill-fortune upon themselves. Thus we explain what is called a *demonic* character as being due to the repetition-compulsion.

But how can this conservative quality of instincts help us to understand the self-destructive tendency? What is the earlier state of things that such an instinct is trying to rein-

state? Now the answer to this question lies near at hand, and opens up a wide vista of possibilities. If it is true that once in an inconceivably remote past, and in an unimaginable way, life arose out of inanimate matter, then, in accordance with our hypothesis, an instinct must at that time have come into being, whose aim it was to abolish life once more and to re-establish the inorganic state of things. If in this instinct we recognize the impulse to self-destruction of our hypothesis, then we can regard that impulse as the manifestation of a *death instinct*, which can never be absent in any vital process. And now the instincts in which we believe separate themselves into two groups; the erotic instincts, which are always trying to collect living substance together into ever larger unities, and the death instincts which act against that tendency, and try to bring living matter back into an inorganic condition. The co-operation and opposition of these two forces produce the phenomena of life to which death puts an end.

You will perhaps shrug your shoulders and say: That is not natural science, that is the philosophy of Schopenhauer. But, Ladies and Gentlemen, why should not a bold thinker have divined something that a sober and painstaking investigation of details subsequently confirms? And after all, everything has been said already, and many people said the same thing before Schopenhauer. And besides, what we have said is not even true Schopenhauer. We do not assert that death is the only aim of life; we do not overlook the presence of life by the side of death. We recognize two fundamental instincts, and ascribe to each of them its own aim. How the two mingle in the vital process, how the death instinct is pressed into the service of Eros, especially when it is turned outwards in the form of aggressiveness—these are problems which remain for future investigation. We can go no further than the point at which this prospect opens up before us. The question whether all instincts without exception do not possess a conservative character, whether the erotic instincts also do not seek the reinstatement of an earlier state of things, when they strive towards the synthesis of living substance into larger wholes—this question, too, must be left unanswered.

We have wandered somewhat far from our thesis, but I will tell you the starting-point of these reflections upon the theory of the instincts. It was the same thing that led us to a revision of the relation between the ego and the uncon-

scious: the impression we received from our analytical work that the patient who puts up a resistance very often knows nothing about it. But he is unconscious not only of the fact of his resistance but of the motives for it. It was necessary for us to look for these motives or this motive, and we found it, to our surprise, in a strong need for punishment, which we could not help associating with masochistic wishes. The practical value of this discovery is no less than its theoretical importance, for this need for punishment is the worst enemy of our therapeutic efforts. It is satisfied by the suffering which is bound up with the neurosis, and therefore holds fast to the state of illness. It seems as though this factor, the unconscious need for punishment, plays a part in every neurotic disease. The truth of this view is brought home to one in the most convincing way by cases in which we see neurotic suffering vanish at the appearance of suffering of another kind. I will give you an instance of this. I once succeeded in freeing a middle-aged spinster from a symptom-complex that had condemned her to a miserable existence for about fifteen years, and had quite prevented her from taking any part in life. She felt that she was now restored to health, and plunged into a whirl of activity in order to develop her talents, which were by no means small, and derive a little appreciation, enjoyment, and success from life before it was too late. But all her attempts ended in its being made clear to her, or in her seeing for herself, that she was too old to effect anything in that direction. Every time this happened, the next step for her would have been a relapse into her illness, but that she could no longer bring about; instead of it an accident would always befall her, which incapacitated her for some time and caused her suffering. She would fall down and sprain her foot, or injure her knee, or else hurt her hand while she was doing something or other. As soon as she saw how great a part she herself played in these apparently chance accidents, she altered her technique, as one might say. Instead of accidents she contracted on the same occasions slight illnesses, such as catarrhs, sore throats, influenzal conditions, or rheumatic swellings, until at last when she made up her mind to resign herself to inactivity, the whole business came to an end.

As to the origin of this unconscious need for punishment, there can be, I think, no doubt. It behaves like a part of the conscience, like the prolongation of conscience into the unconscious; and it must have the same origin as

conscience, that is to say, it will correspond to a piece of aggressiveness which has been internalized and taken over by the super-ego. If only the words were less incongruous, we should be justified, for all practical purposes, in calling it *an unconscious sense of guilt*. Theoretically, as a matter of fact, we are in doubt whether we ought to suppose that all aggressiveness that has turned back from the external world is bound by the super-ego, and so used against the ego, or whether a part of it carries on its silent sinister activity as a free destructive instinct in the ego and the id. Probably there is a division of this kind, but we know nothing further about it. When first the super-ego is set up, there is no doubt that that function is endowed with that part of the child's aggressiveness against its parents for which it can find no discharge outwards on account of its love-fixation and external difficulties; and, for this reason, the severity of the super-ego need not correspond to the severity of its upbringing. It is quite likely that when on subsequent occasions aggressiveness is suppressed, the instinct follows the path which was opened to it at that decisive period.

People in whom this unconscious sense of guilt is dominant, distinguish themselves under analytic treatment by exhibiting what is so unwelcome from the point of view of prognosis—a negative therapeutic reaction. In the normal course of events, if one gives a patient the solution of a symptom, at least the temporary disappearance of that symptom should result; with these patients, on the contrary, the effect is a momentary intensification of the symptom and the suffering that accompanies it. It often needs only a word of praise of their behaviour during the cure, the utterance of a few words of hope as to the progress of the analysis, to bring about an unmistakable aggravation of their condition. A non-analyst would say that they were lacking in the “will to recovery”; from the analytical point of view, their behaviour will appear as an expression of an unconscious sense of guilt, which favours illness with its attendant sufferings and handicaps. The problems raised by the unconscious sense of guilt, its relation to morality, education, criminality and delinquency, is at the present moment the favourite field of investigation for psycho-analysts. Here we have quite unexpectedly emerged into the open from the mental underworld. I cannot take you any further, but I will detain you for a few moments before I stop with one further considera-

tion. We have got into the habit of saying that our civilization is built up at the cost of our sexual impulses, which are inhibited by society, being partly repressed, but partly, on the other hand, made use of for new aims. However proud we may be of our cultural achievements, we have admitted that it is by no means easy to satisfy the requirements of this civilization and to feel comfortable in its midst, because the restriction of the instincts which it involves lay a heavy psychological burden on our shoulders. Now what we have recognized as true of the sexual instincts holds to the same extent, and perhaps to an even greater extent, for the other instincts, for those of aggression. It is they above all that make communal existence difficult, and threaten its permanence. The limitation of aggression is the first and perhaps the hardest sacrifice which society demands from each individual. We have learnt in what an ingenious way this unruly element is tamed. The setting up of the super-ego, which makes the dangerous aggressive impulses its own, is like introducing a garrison into a province that is on the brink of rebellion. But, on the other hand, looking at it from a purely psychological point of view, one has to admit that the ego does not feel at all comfortable when it finds itself sacrificed in this way to the needs of society, when it has to submit itself to the destructive impulses of aggression, which it would have dearly liked itself to set in motion against others. It is like a carrying-over into the region of the mind of the dilemma—eat or be eaten—which dominates the organic world. Fortunately, the instincts of aggression are never alone, they are always alloyed with the erotic ones. In the cultural conditions which man has created for himself, the erotic instincts have much to mitigate and much to avert.

### LECTURE 33

#### THE PSYCHOLOGY OF WOMEN

**LADIES AND GENTLEMEN:** The whole time that I have been preparing the lectures I am giving you, I have been struggling with an internal difficulty. I feel, as one might say, uncertain of the terms of my licence. It is quite true that in the course of fifteen years' work, psycho-analysis has altered and grown; but in spite of that, an introduction to psycho-analysis might be left unchanged and unexpanded. It is always at the back of my mind that there is no *raison d'être* for these lectures. For analysts I say too little and nothing at all that is new, while to

you I say too much and relate things which you are not in a position to understand and which are not for your ears. I have looked about for excuses, and have tried to justify each of my lectures on different grounds. The first, the one about the theory of dreams, was intended to put you back at once into the atmosphere of analysis, and to show you how durable our hypotheses have proved themselves to be. I was tempted to give the second, which traced the connection between dreams and the so-called occult, by the opportunity it afforded of saying something about a field of research in which at the present time prejudiced expectation is struggling against passionate opposition; and I allowed myself to hope that you would not refuse me your company on this expedition, but would follow me with a judgment educated to tolerance by example of psycho-analysis. The third lecture, which dealt with the anatomy of the personality, certainly made the severest demands upon you, so strange was its subject-matter; but it was quite impossible for me to withhold from you this first contribution to ego-psychology, and, if we had been in possession of the material fifteen years ago, I should have had to mention it then. Finally, the last lecture, which you have probably followed only with the greatest difficulty, contained some necessary emendations and new attempts at the solution of the most important problems; and my introduction would have been positively misleading if I had kept silent about them. You see how it is that when one tries to excuse oneself, it comes out in the end that everything was inevitable, that everything was pre-ordained. I submit to fate; and I beg that you will do the same.

Nor should today's lecture find a place in an introduction; but it may serve to give you an example of the detailed work of analysis, and there are two things I can add in its favour. It contains nothing but observed facts, with hardly any speculative additions, and it is concerned with a theme which claims your attention almost more than any other. Throughout the ages, the problem of woman has puzzled people of every kind—

*Heads in hieroglyphic caps,  
Heads in turbans, and black bonnets,  
Heads bewigged and thousand other  
Poor and sweating heads of humans. . . .*  
Heine, Nordsee.

You too will have pondered over this question in so far as you are men; from the women

among you that is not to be expected, for you are the riddle yourselves. Male or female is the first differentiation that you make when you meet another human being, and you are used to making that distinction with absolute certainty. Anatomical science shares your certainty in one point, but not much more. Male is the male sexual secretion, the spermatozoon, and its carrier; female is the egg, and the organism that contains it. In each sex, organs have been formed which exclusively subserve the sexual functions; they have probably been developed from the same basis into two different formations. In both sexes, moreover, the other organs, the shape of the body and the tissues are influenced by sex (the so-called secondary sexual characters), but this influence is irregular and varying in degree. And then science tells you something that runs counter to your expectations, and is probably calculated to confuse your feelings. It points out to you that parts of the male sexual apparatus are also to be found in the body of the female, although in a rudimentary condition, and vice versa. Science sees in this phenomenon an indication of *bisexuality*, as though the individual were neither man nor woman, but both at the same time, only rather more the one than the other. It then expects you to make yourselves familiar with the idea that the proportions in which the masculine and the feminine mingle in an individual are subject to quite extraordinary variations. And even though, apart from very rare cases, only one kind of sexual product—ova or seminal cells—is present in any one individual, you will go wrong if you take this factor as being of decisive importance, and you must conclude that what constitutes masculinity or femininity is an unknown element which it is beyond the power of anatomy to grasp.

Can psychology do any better? We are used to consider masculine and feminine as mental qualities as well, and have also carried the notion of bisexuality over into mental life. We speak of a human being, whether male or female, behaving in a masculine or a feminine way. But you will at once observe that that is simply following the lead of anatomy and convention. You can give the concepts of masculine and feminine no new content. The difference is not a psychological one; when you say "masculine," you mean as a rule *active*, and when you say "feminine" you mean *passive*. Now it is quite true that there is such a correlation. The male sexual cell is active and mobile; it seeks out the female one, while the

latter, the ovum, is stationary and waits passively. This behaviour of the elementary organisms of sex is more or less a model of the behaviour of the individuals of each sex in sexual intercourse. The male pursues the female for the purpose of sexual union, seizes her, and pushes his way into her. But with that you have, so far as psychology goes, reduced the quality of masculinity to the factor of aggressiveness. You will begin to doubt whether you have hit upon anything fundamental here, when you consider that in many classes of animals the female is the stronger and more aggressive party, and the male is only active in the single act of sexual intercourse. That is the case, for instance, with spiders. The functions of caring for the young, too, and of rearing them, which seems to us so essentially feminine, are not, among animals, always associated with the female sex. In some species of animals, quite high in the scale, one finds that the sexes share in the duties of looking after the young, or even that the male devotes himself to it alone. Even in the sphere of human sexual life, one soon notices how unsatisfactory it is to identify masculine behaviour with activity and feminine with passivity. The mother is in every sense of the word active in her relations with her child; it is just as true to say that she gives suck to the child, as that she lets it suck her breasts. The further you go from the sexual field in the narrower sense of the word the more apparent it becomes that the two ideas do not coincide. Women can display great activity in a variety of directions, while men cannot live together with their kind unless they develop a high degree of passive pliability. If you thereupon say that these facts precisely prove that men and women are psychologically bisexual, I shall infer that you have decided to identify activity with masculinity and passivity with femininity. But I advise you not to do that. It seems to me to serve no good purpose and to give us no new information.

One might make an attempt to characterize femininity psychologically by saying that it involves a preference for passive aims. That is naturally not the same as passivity; it may require a good deal of activity to achieve a passive end. It may be that the part played by women in the sexual function leads them to incline towards passive behaviour and passive aims, and that this inclination extends into their ordinary life to a greater or less degree, according to whether the influence of her sexual life as a model is limited or far-reaching. But we

must take care not to underestimate the influence of social conventions, which also force women into passive situations. The whole thing is still very obscure. We must not overlook one particularly constant relation between femininity and instinctual life. The repression of their aggressiveness, which is imposed upon women by their constitutions and by society, favours the development of strong masochistic impulses, which have the effect of binding erotically the destructive tendencies which have been turned inwards. Masochism is, then, as they say, truly feminine. But when, as so often happens, you meet with masochism in men, what else can you do but say that these men display obvious feminine traits of character?

You are now prepared for the conclusion that psychology cannot solve the riddle of femininity. The solution must, I think, come from somewhere else, and it cannot come until we have learned in general how the differentiation of living creatures into two sexes came about. We know nothing whatever about the matter, and yet sex-differentiation is a most remarkable characteristic in organic life, and one by which it is sharply cut off from inanimate nature. Meanwhile, we shall find plenty to occupy ourselves with in the study of those human individuals who are characterized as manifestly or preponderantly female by the possession of female genitals. It is in harmony with the nature of psycho-analysis that it does not try to describe what women are—that would be a task which it could hardly perform—but it investigates the way in which women develop out of children with their bisexual disposition. We have learnt a certain amount about this recently, thanks to the fact that several excellent women analysts have begun to work on the problem. A special piquancy has been lent to the discussion of this subject by the question of the difference between the sexes; for, whenever a comparison was made which seemed to be unfavourable to their sex, the ladies were able to express a suspicion, that we, the men analysts, had never overcome certain deep-rooted prejudices against the feminine, and that consequently our investigations suffered from bias. On the other hand, on the basis of bisexuality, we found it easy to avoid any impoliteness. We had only to say: "This does not apply to you. You are an exception, in this respect you are more masculine than feminine."

In approaching the study of the sexual development of women we start with two preconceptions: firstly, that, as in the case of men,

the constitution will not adapt itself to its function without a struggle; and secondly, that the decisive changes will have been set in motion or completed before puberty. Both of these preconceptions turn out to be justified. Further, a comparison with what happens in the case of the boy shows us that the development of the little girl into a normal woman is more difficult and more complicated; for she has two additional tasks to perform, to which there is nothing corresponding in the development of the man. Let us follow the parallel from the very beginning. Certainly the original material is different in the boy and the girl; it does not require psycho-analysis to find that out. The difference in the formation of their genital organs is accompanied by other bodily differences, which are too familiar for me to need to mention them. In their instinctual disposition, as well, there are differences which foreshadow the later nature of the woman. The little girl is as a rule less aggressive, less defiant, and less self-sufficient; she seems to have a greater need for affection to be shown her, and therefore to be more dependent and docile. The fact that she is more easily and more quickly taught to control her excretions is very probably only the result of this docility; urine and stool are, as we know, the first gifts that the child can offer to those who look after it, and control over them is the first concession which can be wrung from the instinctual life of the child. One gets the impression, too, that the little girl is more intelligent and more lively than the boy of the same age; she is more inclined to meet the external world half way, and, at the same time, she makes stronger object-cathexes. I do not know whether the view that she gets a start in development has been confirmed by more exact observations, but in any case it is quite clear that the little girl cannot be called intellectually backward. But these sexual differences are of no great importance; they can be out-balanced by individual variations. For the purposes which we have immediately in view they may be left on one side.

Both sexes seem to pass through the early phases of libidinal development in the same way. One might have expected that already in the sadistic-anal phase we should find that the girl showed less aggressiveness; but this is not the case. Women analysts have found from the analysis of children's play that the aggressive impulses of little girls leave nothing to be desired as regards copiousness and violence.

With the onset of the phallic phase the difference between the sexes becomes much less important than their similarities. We are now obliged to recognize that the little girl is a little man. As we know, in the boy this phase is characterized by the fact that he has discovered how to obtain pleasurable sensations from his little penis, and associates its state of excitation with his ideas about sexual intercourse. The little girl does the same with her even smaller clitoris. It seems as though, with her, all her masturbatory actions center round this penis-equivalent, and that the actual female vagina is still undiscovered by both sexes. It is true that, here and there, reports have been made that tell us of early vaginal sensations as well; but it cannot be easy to discriminate between these and anal sensations or from sensations of the vaginal vestibule; in any case they cannot play a very important rôle. We may assume that, in the phallic phase of the girl, the clitoris is the dominant erotogenic zone. But it is not destined to remain so; with the change to femininity, the clitoris must give up to the vagina its sensitivity, and, with it, its importance, either wholly or in part. This is one of the two tasks which have to be performed in the course of the woman's development; the more fortunate man has only to continue at the time of his sexual maturity what he has already practised during the period of early sexual expansion.

We shall return to the part played by the clitoris, but shall now pass on to the second task with which the girl's development is burdened. The first love-object of the boy is his mother, and she remains as such in the formation of his Oedipus-complex, and, ultimately, throughout his whole life. For the little girl, too, her mother must be her first object (together with figures of nurses and other attendants that merge into hers); the first object-cathexes, indeed, follow the lines of the satisfaction of the great and simple needs of life, and the circumstances in which the child is nursed are the same for both sexes. In the Oedipus situation, however, the father has become the little girl's love-object, and it is from him that, in the normal course of development, she should find her way to her ultimate object-choice. The girl has, then, in the course of time to change both her erotogenic zone and her object, while the boy keeps both of them unchanged. The question then arises of how this comes about. In particular, how does the little girl pass from an attachment to her

mother to an attachment to her father? or, in other words, how does she pass from her masculine phase into the feminine phase which has been biologically marked out for her?

Now it would provide us with an ideally simple solution of the problem if we could assume that, from a certain age onwards, the elementary influence of heterosexual attraction makes itself felt, and draws the little girl towards men, while the same principle allows the boy to keep to his mother. One could even assume, further, that, in doing this, children are following a hint given them by the sexual preferences of their parents. But things are not so convenient as this. We hardly know whether we can seriously believe in the mysterious and unanalysable force, of which the poets sing so enthusiastically. Painstaking investigations have resulted in findings of quite a different kind, the material for which, at all events, was easily obtainable. You must know that the number of women who until late in life remain tenderly attached to father-objects, or indeed to their real fathers, is very large. We have made the most surprising discoveries about these women who display intense and prolonged father-fixations. We knew, of course, that there had been an earlier stage in which they were attached to their mother; but we did not know that it was so rich in content, that it persisted so long, and that it could leave behind it so many occasions for fixations and predispositions. During this time, their father is no more than an irksome rival. In many cases the attachment to the mother lasts beyond the fourth year; almost everything that we find later in the father-relation was already present in that attachment, and has been subsequently transferred on to the father. In short, we gain the conviction that one cannot understand women, unless one estimates this *pre-oedipal attachment to the mother* at its proper value.

Now we should very much like to know what the libidinal relations of the little girl to her mother are. The answer is that they are manifold. Since they pass through all the three phases of infantile sexuality, they take on the characteristics of each separate phase and express themselves by means of oral, sadistic-anal, and phallic wishes. These wishes represent active as well as passive impulses; if one relates them to the differentiation of the sexes which comes about later (which one should avoid doing as far as possible), one can speak of them as masculine and feminine. They are, in addition, completely ambivalent—both of a tender and

of a hostile-aggressive nature. It often happens that the hostile wishes only become apparent after they have been turned into anxiety-ideas. It is not always easy to point out the way in which these early sexual wishes are formulated. What is most clearly expressed is the desire to get the mother with child as well as the corresponding one, to have a child by the mother; both belong to the phallic phase, and seem sufficiently strange, though their existence is established beyond all doubt by analytic observation. The attraction of these investigations lies in the extraordinary facts which they bring to light. Thus, for instance, one discovers the fear of being murdered or poisoned, which may later on form the nucleus of a paranoid disorder, already present in this pre-oedipal stage and directed against the mother. Or, to take another case. You will remember that interesting episode in the history of analytical research which caused me so many painful hours? At the time when my main interest was directed on to the discovery of infantile sexual traumas, almost all my female patients told me that they had been seduced by their fathers. Eventually, I was forced to the conclusion that these stories were false, and thus I came to understand that hysterical symptoms spring from phantasies and not from real events. Only later was I able to recognize in this phantasy of seduction by the father the expression of the typical Oedipus-complex in woman. And now we find, in the early pre-oedipal history of girls, the seduction-phantasy again; but the seducer is invariably the mother. Here, however, the phantasy has a footing in reality; for it must in fact have been the mother who aroused (perhaps for the first time) pleasurable sensations in the child's genitals in the ordinary course of attending to its bodily needs.

I dare say that you are prepared to suspect that this description of the richness and strength of the sexual relations of the little girl to her mother is very much exaggerated. One has, after all, plenty of opportunity of watching little girls, and one notices nothing of the sort. But the objection cannot be sustained. One can see enough of such things in children, if one understands how to observe them, and, besides this, you must consider how little the child is able to give preconscious expression to its sexual wishes, and how little it can communicate them. We are, therefore, acting entirely within our rights in studying the subsequent traces and consequences of this emotional field in persons in whom these de-

velopmental processes show a particularly clear, or even exaggerated, growth. Pathology, as you know, has always assisted us, by isolation and exaggeration, in making recognizable things which would normally remain hidden. And since our researches have been carried out on people who are by no means grossly abnormal, we may, I think, consider the results of them worthy of belief.

We will now turn our attention to the question of why this strong attachment of the girl to her mother comes to grief. We are aware that that is what usually happens to it; it is fated to give way to an attachment to her father. And here we stumble on a fact which points in the right direction. This step in development is not merely a question of a change of object. The turning away from the mother occurs in an atmosphere of antagonism; the attachment to the mother ends in hate. Such a hatred may be very marked and may persist throughout an entire lifetime; it may later on be carefully overcompensated; as a rule, one part of it is overcome, while another part persists. The outcome is naturally very strongly influenced by the actual events of later years. We will confine ourselves to studying this hatred at the actual time at which the turn towards the father takes place, and to inquiring into its motives. We are then met by a long list of complaints and grievances, levelled at the mother, which are intended to justify the antagonistic feelings of the child; they vary much in value, and we shall examine them further. Many are obvious rationalizations, and we have yet to find the true source of the antagonism. I hope you will bear with me, if on this occasion I conduct you through all the details of a psycho-analytical investigation.

The complaint against the mother that harks back furthest is that she has given the child too little milk, which is taken as indicating a lack of love. Now this complaint has a certain justification in the civilized human family. The mothers often have not enough nourishment for their children, and content themselves with nursing them for nine months or six or even less. Among primitive peoples, children remain at the breast for as long as two or three years. The figure of the wet-nurse is as a rule merged in that of the mother; where this does not take place, the complaint against the mother takes another form, namely, that she sent the nurse, who was so ready to feed the child, away too soon. But whatever may have been the true state of affairs, it is impossible that the child's

complaint can be as often justified as it is met with. It looks far more as if the desire of the child for its first form of nourishment is altogether insatiable, and as if it never got over the pain of losing the mother's breast. I should not be at all surprised if an analysis of a member of a primitive race, who must have sucked the mother's breast when he could already run and talk, brought the same complaint to light. It is probable, too, that the fear of poisoning is connected with weaning. Poison is the nourishment that makes one ill. Perhaps, moreover, the child traces his early illnesses back to this frustration. It requires a good deal of intellectual training before we can believe in chance; primitive and uneducated people, and certainly children, can give a reason for everything that happens. Perhaps this reason was originally a motive (in the animistic sense). In many social strata, even to this day, no one can die, without having been done to death by some one else, preferably by the doctor. And the regular reaction of a neurotic to the death of some one intimately connected with him is to accuse himself of being the cause of the death.

The next accusation against the mother flares up when the next child makes its appearance in the nursery. If possible, this complaint retains the connection with oral frustration: the mother could not or would not give the child any more milk, because she needed the nourishment for the new arrival. In cases where the two children were born so close together that lactation was interfered with by the second pregnancy, this complaint has a real foundation. It is a remarkable fact that even when the difference between the children's ages is only eleven months, the older one is nevertheless able to take in the state of affairs. But it is not only the milk that the child grudges the undesired interloper and rival, but all the other evidences of motherly care. It feels that it has been dethroned, robbed, and had its rights invaded, and so it directs a feeling of jealous hatred against its little brother or sister, and develops resentment against its faithless mother, which often finds expression in a change for the worse in its behaviour. It begins to be naughty, irritable, intractable, and unlearns the control which it has acquired over its excretions. All this has been known for a long time, and is accepted as self-evident, but we seldom form a right idea of the strength of these jealous impulses, of the tenacious hold they have on the child, and the amount of influence they exert on its later development.

These jealous feelings are particularly important because they are always being fed anew during the later years of childhood, and the whole shattering experience is repeated with the arrival of every new brother or sister. Even if the child remains its mother's favourite, things are not very different; its demands for affection are boundless; it requires exclusive attention and will allow no sharing whatever.

A potent source of the child's antagonism against its mother is found in its many sexual wishes, which change with its libidinal phases. These cannot, for the most part, be satisfied. The strongest of these frustrations occurs in the phallic stage, when the mother forbids pleasurable activities centring round the genital organs—often with an accompaniment of harsh threats and every indication of disapproval—activities to which, after all, she herself stimulated the child. It might be thought that we had here motives enough for the little girl's alienation from her mother. In that case it might be our view that estrangement follows inevitably from the nature of infantile sexuality, from the child's unlimited demands for love and the unfulfillable nature of its sexual wishes. One might even believe that this first love relation of the child is doomed to extinction for the very reason that it is the first, for these early object-cathexes are always ambivalent to a very high degree; alongside the child's intense love there is always a strong aggressive tendency present, and the more passionately the child loves an object, the more sensitive it will be to disappointments and frustrations coming from it. In the end, the love is bound to capitulate to the accumulated hostility. Or, on the other hand, one might reject the idea of a fundamental ambivalence of this kind in the libidinal cathexes, and point to the fact that it is the peculiar nature of the mother-child relationship which leads, equally inevitably, to the disturbance of the child's love, since even the mildest form of education cannot avoid using compulsion and introducing restrictions, and every such encroachment on its freedom must call forth, as a reaction in the child, a tendency to rebellion and aggressiveness. A discussion of these possibilities might, I think, be very interesting, but at this point an objection suddenly arises, which forces our attention in another direction. All of these factors—slights, disappointments in love, jealousy, and seduction followed by prohibition—operate as well in the relationship between the boy and his mother, and yet are not sufficient to alien-

ate him from the mother-object. If we do not find something which is specific for the girl, and which is not present at all, or not present in the same way, in the case of the boy, we shall not have explained the ending of the girl's attachment to her mother.

I think that we have discovered this specific factor, in a place where we might indeed have expected it, but in a surprising form. In a place where we might have expected it, I say, for it lies in the castration complex. The anatomical distinction between the sexes must, after all, leave its mark in mental life. It was a surprise, however, to discover from analyses that the girl holds her mother responsible for her lack of a penis, and never forgives her for that deficiency.

You will note that we ascribe a castration-complex to the female sex as well as to the male. We have good grounds for doing so, but that complex has not the same content in girls as in boys. In the boy, the castration-complex is formed after he has learnt from the sight of the female genitals that the sexual organ which he prizes so highly is not a necessary part of every human body. He remembers then the threats which he has brought on himself by his playing with his penis, he begins to believe in them, and thence forward he comes under the influence of *castration-anxiety*, which supplies the strongest motive force for his further development. The castration-complex in the girl, as well, is started by the sight of the genital organs of the other sex. She immediately notices the difference, and—it must be admitted—its significance. She feels herself at a great disadvantage, and often declares that she would "like to have something like that too," and falls a victim to *penis-envy*, which leaves ineradicable traces on her development and character-formation, and, even in the most favourable instances, is not overcome without a great expenditure of mental energy. That the girl recognizes the fact that she lacks a penis, does not mean that she accepts its absence lightly. On the contrary, she clings for a long time to the desire to get something like it, and believes in that possibility for an extraordinary number of years; and even at a time when her knowledge of reality has long since led her to abandon the fulfilment of this desire as being quite unattainable, analysis proves that it still persists in the unconscious and retains a considerable charge of energy. The desire after all to obtain the penis for which she so much longs may even contribute to the motives that impel a

grown-up woman to come to analysis; and what she quite reasonably expects to get from analysis, such as the capacity to pursue an intellectual career, can often be recognized as a sublimated modification of this repressed wish.

One cannot very well doubt the importance of penis-envy. Perhaps you will regard the hypothesis that envy and jealousy play a greater part in the mental life of women than they do in that of men as an example of male unfairness. Not that I think that these characteristics are absent in men, or that they have no other origin in women except envy of the penis, but I am inclined to ascribe the greater amount of them to be found in women to this latter influence. Many analysts, however, tend to minimize the importance of this first wave of penis-envy in the phallic phase. They think that the signs one comes across of this attitude in women are in the main a secondary formation which has come about through regression to the early infantile impulse in question on the occasion of some subsequent conflict. Now this is one of the general problems of depth psychology. In the case of many pathological—or merely unusual—instinctual attitudes, for example with all sexual perversions, the question arises how much of their force is to be attributed to early infantile fixations and how much to the influence of later experiences and developments. It is almost always a question of complementary series, such as we have postulated when dealing with the aetiology of the neuroses. Both sets of factors share in the causation in a varying proportion; a less in the one set will be balanced by a more in the other. The infantile factor in every case paves the way; it is not always the decisive force, though it often is. But with regard to the particular case of penis-envy, I should like to come down decidedly in favour of the preponderance of the infantile factor.

The discovery of her castration is a turning-point in the life of the girl. Three lines of development diverge from it; one leads to sexual inhibition or to neurosis, the second to a modification of character in the sense of masculinity complex, and the third to normal femininity. We have learnt a good deal, though not everything, about all three. The fundamental content of the first is that the little girl, who has hitherto lived a masculine life, and has been able to obtain pleasure through the excitation of her clitoris, and has connected this behaviour with the sexual wishes (often of an active character) which she has directed towards her mother,

finds her enjoyment of phallic sexuality spoilt by the influence of penis-envy. She is wounded in her self-love by the unfavourable comparison with the boy who is so much better equipped, and therefore gives up the masturbatory satisfaction which she obtained from her clitoris, repudiates her love towards her mother, and at the same time often represses a good deal of her sexual impulses in general. No doubt this turning away from her mother does not come to pass at one blow, for at first the girl looks on her castration as a personal misfortune, and only gradually extends it to other females, and eventually to her mother. Her love had as its object the phallic mother; with the discovery that the mother is castrated it becomes possible to drop her as a love-object, so that the incentives to hostility which have been so long accumulating, get the upper hand. This means, therefore, that, as a result of the discovery of the absence of a penis, women are as much depreciated in the eyes of the girl as in the eyes of the boy, and later, perhaps, of the man.

You all know what an overwhelming aetiological importance is attributed by neurotics to their masturbatory practices. They make them responsible for all their troubles, and we have the greatest difficulty in getting them to believe that they are wrong. But, as a matter of fact, we ought to admit that they are in the right, for masturbation is the executive agent of infantile sexuality, from the faulty development of which they are suffering. The difference is that what the neurotics are blaming is the masturbation of the pubertal stage; the infantile masturbation, which is the one that really matters, has for the most part been forgotten by them. I wish I could find an opportunity for giving you a circumstantial account of how important all the factual details of early masturbation are in determining the subsequent neurosis or character of the individual concerned—such details as whether it was discovered or not, how the parents combated it or whether they permitted it, and whether the subject succeeded in suppressing it himself. All these details will have left indelible traces upon his development. But, in fact, I am relieved that it is not necessary for me to do this; it would be a difficult and weary task, and at the end you would embarrass me because you would quite certainly ask for some practical advice as to how one should behave towards the masturbation of small children as a parent or educator. The history of the development of girls, which is the subject I am telling you

about, offers an instance of the child itself striving to free itself from masturbation. But it does not always succeed. Where penis-envy has aroused a strong impulse against clitoritic masturbation, but where the latter will not give way, there follows a fierce battle for freedom, in which the girl herself takes over, as it were, the rôle of the mother whom she has set aside, and expresses her whole dissatisfaction with the inferior clitoris, by striving against the gratification derived from it. Many years later, when her masturbatory activity has long ago been suppressed, we may find an interest persisting which we must interpret as a defence against the temptation, which she still fears. It finds expression in feelings of sympathy for persons to whom she ascribes similar difficulties; it may enter into her motives for marriage, and may indeed determine her choice of a husband or lover. The settling of the problem of infantile masturbation is truly no easy or unimportant task.

When the little girl gives up clitoritic masturbation, she surrenders a certain amount of activity. Her passive side has now the upper hand, and in turning to her father she is assisted in the main by passive instinctual impulses. You will see that a step in development, such as this one, which gets rid of phallic activity, must smooth the path for femininity. If in the process not too much is lost through repression, this femininity may prove normal. The wish with which the girl turns to her father, is, no doubt, ultimately the wish for the penis, which her mother has refused her and which she now expects from her father. The feminine situation is, however, only established when the wish for the penis is replaced by the wish for a child—the child taking the place of the penis, in accordance with the old symbolic equation. It does not escape us that at an earlier stage the girl has already desired a child, before the phallic phase was interfered with; that was the meaning of her playing with dolls. But this play was not really an expression of her femininity, it served, in identifying her with her mother, the purpose of substituting activity for passivity. She was the mother, and the doll was herself; now she could do everything to the doll that her mother used to do with her. Only with the onset of the desire for a penis does the doll-child become a child by the father, and, thence-forward, the strongest feminine wish. Her happiness is great indeed when this desire for a child one day finds a real fulfilment; but especially is this so if the child is a little

boy, who brings the longed-for penis with him. In the idea of having a child by the father, the accent is often enough placed on the child, and not on the father. Thus the old masculine wish for the possession of a penis still shows under the completely developed femininity. But perhaps we should rather think of this desire for a penis as something essentially feminine in itself.

With the transference of the child-penis wish on to her father, the girl enters into the situation of the Oedipus-complex. The hostility against her mother, which did not require to be newly created, now receives a great reinforcement, for her mother becomes a rival, who gets everything from her father that she herself wants. The girl's Oedipus-complex has long concealed from us the pre-oedipal attachment to her mother which is so important and which leaves behind it such lasting fixations. For the girl, the Oedipus situation is the conclusion of a long and difficult period of development; it is a kind of temporary solution of her problem, a state of equilibrium which is not lightly to be given up, especially as the onset of the latency period is not far off. And here we notice a difference between the two sexes in the relation between the Oedipus-complex and the castration-complex, a difference which is probably a momentous one. The boy's Oedipus-complex, in which he desires his mother and wants to get rid of his father as a rival, develops naturally out of the phase of phallic sexuality. The threat of castration, however, forces him to give up this attitude. Under the influence of the danger of losing his penis, he abandons his Oedipus-complex; it is repressed and in most normal cases entirely destroyed, while a severe super-ego is set up as its heir. What happens in the case of the girl is almost the opposite. The castration-complex prepares the way for the Oedipus-complex instead of destroying it; under the influence of her penis-envy, the girl is driven from her attachment to her mother and enters the Oedipus situation, as though it were a haven of refuge. When the fear of castration disappears, the primary motive is removed, which has forced the boy to overcome his Oedipus-complex. The girl remains in the Oedipus situation for an indefinite period; she only abandons it late in life, and then incompletely. The formation of the super-ego must suffer in these circumstances; it cannot attain the strength and independence which give it its cultural importance, and feminists are not pleased if one points to the way in which this factor affects

the development of the average feminine character.

Let us now go back a little. We have mentioned, as the second possible reaction after the discovery of female castration, the development of a strong masculinity complex. What is meant by this is that the girl refuses, as it were, to accept the unpalatable fact, and, in an outburst of defiance, exaggerates still further the masculinity which she has displayed hitherto. She clings to her clitoritic activities, and takes refuge in an identification either with the phallic mother, or with the father. What is the determinant which leads to this state of affairs? We can picture it as nothing other than a constitutional factor: the possession of a greater degree of activity, such as is usually characteristic of the male. The essential thing about the process is, after all, that at this point of development the onset of passivity, which makes possible the change over to femininity, is avoided. The most extreme achievement of this masculinity complex seems to occur when it influences the girl's object-choice in the direction of manifest homosexuality. Analytic experience teaches us, it is true, that female homosexuality is seldom or never a direct continuation of infantile masculinity. It seems to be characteristic of female homosexuals that they too take the father as love-object for a while, and thus become implicated in the Oedipus situation. Then, however, they are driven by the inevitable disappointments which they experience from the father into a regression to their early masculinity complex. One must not overestimate the importance of these disappointments; girls who eventually achieve femininity also experience them without the same results. The preponderance of the constitutional factor seems undeniable, but the two phases in the development of female homosexuality are admirably reflected in the behaviour of homosexuals, who just as often and just as obviously play the parts of mother and child towards each other as those of man and wife.

What I have been telling you is what one might call the pre-history of women. It is an achievement of the last few years, and you may have been interested in it as an example of detailed work in analysis. Since women are our theme, I am going to permit myself to mention by name a few women to whom this investigation owes important contributions. Dr. Ruth Mack Brunswick was the first to describe a case of neurosis which went back to a fixation in the pre-oedipal state, and in which the Oedi-

pus situation was not reached at all. It took the form of paranoia with delusions of jealousy, and proved accessible to treatment. Dr. Jeanne Lamplde Groot has, from her own unequivocal observations, established the fact of the girl's phallic activities towards her mother which seem so hard to believe. Dr. Helene Deutsch has shown that the erotic behaviour of homosexual woman reproduces the mother-child relationship.

It is not my intention to trace the further course of femininity through puberty up to the time of maturity. Our views on the subject are indeed not complete enough for me to do so. In what follows, I will merely mention a few separate points. Bearing in mind the early history of femininity, I will emphasize the fact that its development remains open to disturbance from the traces left behind by the previous masculine period. Regressions to fixations at these pre-oedipal phases occur very often; in many women we actually find a repeated alternation of periods in which either masculinity or femininity has obtained the upper hand. What we men call "the enigma of woman" is probably based in part upon these signs of bisexuality in female life. But another question seems to have become ripe for discussion in the course of these investigations. We have called the motor force of sexual life *libido*. This sexual life is dominated by the polarity, masculine-feminine; one is therefore tempted to consider the relation of the libido to this polarity. It would not be surprising if it turned out that each form of sexuality had its own special form of libido, so that one kind of libido pursued the aims of the masculine sexual life, and the other those of the feminine. Nothing of the sort, however, is the case. There is only one libido which is as much in the service of the male as of the female sexual function. To it itself we can assign no sex; if, in accordance with the conventional analogy between activity and masculinity, we choose to call it masculine, we must not forget that it also includes impulses with passive aims. Nevertheless the phrase *feminine libido* cannot possibly be justified. It is our impression that more violence is done to the libido when it is forced into the service of the female function; and that—to speak teleologically—Nature has paid less careful attention to the demands of the female function than to those of masculinity. And—again speaking teleologically—this may be based on the fact that the achievement of the biological aim is entrusted to the aggressiveness of the

male, and is to some extent independent of the co-operation of the female.

The sexual frigidity of women, the frequency of which seems to confirm this last point, is still a phenomenon which is insufficiently understood. Sometimes it is psychogenic, and, if so, it is accessible to influence; but in other cases one is led to assume that it is constitutionally conditioned or even partly caused by an anatomical factor.

I have promised to put before you a few more of the mental characteristics of mature femininity, as we find them in our analytical observation. We do not claim for these assertions more than that they are true on the whole; and it is not always easy to distinguish between what is due to the influence of the sexual function and what to social training. We attribute to women a greater amount of narcissism (and this influences their object-choice) so that for them to be loved is a stronger need than to love. Their vanity is partly a further effect of penis-envy, for they are driven to rate their physical charms more highly as a belated compensation for their original sexual inferiority. Modesty, which is regarded as a feminine characteristic *par excellence*, but is far more a matter of convention than one would think, was, in our opinion, originally designed to hide the deficiency in her genitals. We do not forget that, later on, it takes over other functions. People say that women contributed but little to the discoveries and inventions of civilization, but perhaps after all they did discover one technical process, that of plaiting and weaving. If this is so, one is tempted to guess at the unconscious motive at the back of this achievement. Nature herself might be regarded as having provided a model for imitation, by causing pubic hair to grow at the period of sexual maturity so as to veil the genitals. The step that remained to be taken was to attach the hairs permanently together, whereas in the body they are fixed in the skin and only tangled with one another. If you repudiate this idea as being fantastic, and accuse me of having an *idée fixe* on the subject of the influence exercised by the lack of a penis upon the development of femininity, I cannot of course defend myself.

The conditions of object-choice in women are often enough made unrecognizable by social considerations. Where that choice is allowed to manifest itself freely, it often occurs according to the narcissistic ideal of the man whom the girl would have liked to be. If the girl has

remained attached to her father, if, that is to say, she has remained in the Oedipus-complex, then she chooses according to a father-type. Since, when she turned from her mother to her father, the antagonistic part of her ambivalent feelings remained directed on to her mother, such a choice should ensure a happy marriage. But very often a factor emerges which in general imperils such solutions of the ambivalence-conflict. The antagonism which has been left behind may follow in the wake of the positive attachment, and extend to the new object. The husband, who had in the first instance inherited his position from the father, comes in the course of time to inherit the position of the mother as well. In this way it may easily occur that the second part of a woman's life is taken up with a struggle against her husband, just as the shorter earlier part was occupied with rebellion against her mother. After this reaction has been lived out, a second marriage may easily turn out far more satisfactorily. Another change in a woman's nature, for which neither husband nor wife are prepared, may come about after the first child has been born. Under the influence of her own motherhood, her identification with her mother may be revived (an identification against which she has struggled up to the time of her marriage) and may attract to itself all the libido that she has at her disposal, so that the repetition-compulsion may reproduce an unhappy marriage of the parents. That the old factor of lack of penis has not even yet forfeited its power is seen in the different reactions of the mother according to whether the child born is a son or a daughter. The only thing that brings a mother undiluted satisfaction is her relation to a son; it is quite the most complete relationship between human beings, and the one that is the most free from ambivalence. The mother can transfer to her son all the ambition which she has had to suppress in herself, and she can hope to get from him the satisfaction of all that has remained to her of her masculinity complex. Even a marriage is not firmly assured until the woman has succeeded in making her husband into her child and in acting the part of a mother towards him.

The mother-identification of the woman can be seen to have two levels, the pre-oedipal, which is based on the tender attachment to the mother and which takes her as a model, and the later one, derived from the Oedipus-complex, which tries to get rid of the mother and replace her in her relationship with the father. Much of

both remains over for the future. One is really justified in saying that neither is overcome to any adequate extent during the process of development. But the phase of tender pre-oedipal attachment is the decisive one; it paves the way for her acquisition of those characteristics which will later enable her to play her part in the sexual function adequately, and carry out her inestimable social activities. In this identification, too, she acquires that attractiveness for the man which kindles his oedipal attachment to his mother into love. Only what happens so often is that it is not he himself who gets what he wanted, but his son. One forms the impression that the love of man and the love of woman are separated by a psychological phase-difference.

It must be admitted that women have but little sense of justice, and this is no doubt connected with the preponderance of envy in their mental life; for the demands of justice are a modification of envy; they lay down the conditions under which one is willing to part with it. We say also of women that their social interests are weaker than those of men, and that their capacity for the sublimation of their instincts is less. The former is no doubt derived from the unsocial character which undoubtedly attaches to all sexual relationships. Lovers find complete satisfaction in each other, and even the family resists absorption into wider organizations. The capacity for sublimation is subject to the greatest individual variations. In spite of this I cannot refrain from mentioning an impression which one receives over and over again in analytic work. A man of about thirty seems a youthful, and, in a sense, an incompletely developed individual, of whom we expect that he will be able to make good use of the possibilities of development, which analysis lays open to him. But a woman of about the same age frequently staggers us by her psychological rigidity and unchangeability. Her libido has taken up its final positions and seems powerless to leave them for others. There are no paths open to her for further development; it is as though the whole process had been gone through and remained inaccessible to influence for the future; as though, in fact, the difficult development which leads to femininity had exhausted all the possibilities of the individual. As therapists, we deplore this state of affairs, even when we are successful in removing her sufferings by solving her neurotic conflict.

That is all I had to say to you about the

psychology of women. It is admittedly incomplete and fragmentary, and sometimes it does not sound altogether flattering. You must not forget, however, that we have only described women in so far as their natures are determined by their sexual function. The influence of this factor is, of course, very far-reaching, but we must remember that an individual woman may be a human being apart from this. If you want to know more about femininity, you must interrogate your own experience or turn to the poets, or else wait until science can give you more profound and more coherent information.

### LECTURE 34

#### EXPLANATIONS, APPLICATIONS AND ORIENTATIONS

LADIES AND GENTLEMEN: May I for once, tired, as one might say, of dry topics, speak to you about matters which have very little theoretical importance, but which will be of interest to you in so far as you are friendly disposed towards psycho-analysis? Let us suppose that in a moment of idleness you take up a German or American or English novel, in which you expect to find a description of men and conditions as they are today. After reading a few pages you come upon the first mention of psycho-analysis, and then soon after upon another, even though the context does not seem to require it. You must not imagine that this has anything to do with the application of *depth-psychology*, with a view to a better understanding of the characters in the book or of their behaviour (though, of course, there are quite serious literary works in which this is attempted). No, such references are for the most part contemptuous remarks, by means of which the author seeks to display his wide reading or his intellectual superiority. And you will not always get the impression that he really knows what he is talking about. Or, again, you may go for your recreation to some social gathering; it need not necessarily be in Vienna. After a short time the conversation will turn on psycho-analysis, and you will hear a great variety of people giving their opinion upon it, usually in tones of dogmatic certainty. This judgment is nearly always a derogatory one, often abusive, and at the very least derisive. If you are so imprudent as to disclose the fact that you know something about the subject, every one rushes up to you, and asks for information and explanations, until after a little time you are convinced that all these

severe judgments had been made in the absence of any knowledge; that hardly any of these adversaries have ever had a book about analysis in their hands, or, if they have, that they have never been able to overcome the first resistance which people experience on coming in contact with a new subject.

You may perhaps expect that an introduction to psycho-analysis should give you some indication of what arguments you should use in order to correct these vulgar errors about analysis, what books to recommend for those who want more knowledge, or even what examples from your reading and experience you should bring into the discussion in order to alter the attitude of your interlocutors. I beg you to do nothing of the sort. It would be quite useless, and your wisest course would be to hide your better knowledge altogether. If that is impossible, then restrict yourselves to saying that, so far as you know, psycho-analysis is a special branch of science, that it is exceedingly difficult to understand and to judge, that it is concerned with very serious matters, so that one cannot pass it off with a few jokes, and that it would be better to choose some other topic as a social pastime. Of course, you will not take part in any attempts at interpretation if imprudent people repeat their dreams, and you will resist the temptation to curry favour for analysis by giving accounts of cures that it has brought about.

You may, however, raise the question why these people, whether they write books or make conversation, should behave so badly, and you will incline to the view that the cause does not lie entirely with the people themselves, but with psycho-analysis as well. That is my opinion too; what you meet with in literature and conversation in the shape of prejudice is the after-effect of an earlier judgment, the judgment, namely, which the representatives of official science have passed upon the young science of psycho-analysis. I have already complained about it once before in a historical survey of the subject, and I shall not do so again—perhaps even that was once too often; but indeed there was no logical blunder, no offence against decency and good taste which the scientific opponents of psycho-analysis did not permit themselves in those days. It was a situation such as actually occurred in the middle ages, in which a wrong-doer, or even a mere political opponent, was put in the pillory and exposed to the ill-treatment of the mob. And perhaps you do not fully realize how high up in our

society the mob spirit extends, and to what lengths people will go when they feel that they are a part of a crowd and superior to personal responsibility. At the beginning of those times I stood more or less alone, and I very soon saw that polemics would do no good, and that complaints and appeals to worthier minds were senseless, since there were no courts before which one could plead one's cause. That being so, I took another path; I made use of applied psycho-analysis for the first time by explaining the behaviour of the crowd as an expression of the same resistance which I had to struggle against in my individual patients. I kept off all polemics, and influenced my followers, as they gradually gathered, to do the same. This mode of behaviour was satisfactory. The ban under which analysis was placed in those days has since been lifted; but, just as a belief which has been given up lingers on as a superstition, just as a theory which science has abandoned is preserved as a popular belief, so today the original excommunication of psycho-analysis in scientific circles survives in the mocking contempt of the writers and conversationalists. You will therefore no longer be surprised at their behaviour.

You must not, however, expect the good news that the struggle is at an end, with the recognition of analysis as a science and its admission as a subject for university study. There is no question of that; the battle is still going on, but in a more respectable way. There is another new factor, and that is that in the scientific world a kind of buffer state has been formed between analysis and its opponents, consisting of people who will allow that there is something in analysis (and even believe in it, subject to the most diverting reservations), but who, on the other hand, reject other parts of it, as they are eager to let everyone know. What determines their choice is not easy to guess. It seems to be a matter of personal sympathies. Some take objection to sexuality, others to the unconscious; the existence of symbolism seems to be particularly disliked. The circumstance that the structure of psycho-analysis, although unfinished, nevertheless already possesses a unified organization from which one cannot select elements according to one's whim, seems not to enter the minds of these eclectics. When I consider these half or quarter followers I never get the impression from any of them that their rejections are based on an examination of the material. There are a great many distinguished men who fall

into this category. They are certainly to be excused on the ground that their time and their interests are devoted to other things, to the subjects, in fact, by the mastery of which they have achieved so much. But, that being so, would it not be better for them to reserve their judgments instead of taking sides so strongly? In the case of one of these great men, I once succeeded in making a rapid conversion. He was a world-famous critic, who had followed contemporary trends of thought with benevolent understanding and prophetic vision. I only got to know him when he had already passed his eightieth year, but he was still fascinating in conversation. You can easily guess to whom I am referring. And it was not I who raised the subject of psycho-analysis. He began it by comparing himself in the most modest way with myself, saying: "I am only a literary man, and you are a man of science and a discoverer. But there is one thing I should like to say to you: I have never had any sexual feeling for my mother." "But there's no need at all for you to have been conscious of it," was my reply, "such processes are unconscious in grown-up people." "Oh, so *that's* your idea," he said, greatly relieved, and pressed my hand. We went on talking for a few hours longer on the best of terms. I heard later that during the few remaining years of his life he repeatedly expressed himself in friendly terms about analysis, and liked to make use of what was for him a new word—*repression*.

A well-known saying enjoins us to learn from our enemies. I must own that I have never been able to manage it; but it occurred to me that it might be instructive for you if I were to call up all the reproaches and objections which the opponents of psycho-analysis have levelled at it, and then point out all the obvious misrepresentations and logical blunders which they contain. But on second thought I said to myself that it would not be at all interesting, but wearisome and disagreeable, and would, in fact, be precisely what I have taken such pains to avoid all these years. You will have to excuse me, therefore, if I refrain from following up this line of thought any further and spare you the judgments of our so-called scientific opponents. After all, we are here dealing almost exclusively with people whose sole claim to be heard rests on their impartiality—which they have preserved by keeping away from the facts of psycho-analysis. But I am aware that in other cases you will not let me get away so cheaply. You will point out that,

after all, there are a great many people to whom my last remark does not apply. These people, you will say, have not kept away from analytical experience; they have analysed patients, they have perhaps even been analysed themselves, they were actually my colleagues for some time, and now they have come to other conclusions, and formed other theories, on the basis of which they have left me and have founded independent schools of psycho-analysis. You will expect me to give some explanation of the possibility and meaning of these dissenting movements which have occurred so frequently in the history of analysis.

Very well, then, I will try; but I shall only do it briefly, for it throws less light upon the nature of analysis than you might expect. I am sure that what you think of first will be Adler's Individual Psychology, which in America, for example, is looked on as being equal in importance to our psycho-analysis and as running on parallel lines, and is constantly mentioned in the same breath with it. In reality Individual Psychology has very little to do with analysis, but, for certain historical reasons, lives a sort of parasitic existence at its expense. The qualifications which we have predicated for this group of opponents only apply to the founders of Individual Psychology to a very limited extent. The name itself is unsuitable, and seems to be a product of embarrassment; we cannot assent to any interference with its correct application as meaning the opposite of Group Psychology; for the matter of that our own concern is, first and foremost, the psychology of the human individual. I am not going into an objective criticism of Adler's Individual Psychology today, for that is no part of my program in these lectures; besides which, I have already made such an attempt elsewhere, and I have little occasion for altering what I there said. I will, however, give you an illustration of the impression it makes, by telling you of a small incident which occurred to me in my pre-analytic years.

In the neighbourhood of the little Moravian town in which I was born and which I left as a child of three years old, there is a modest health resort, beautifully placed in a setting of green. During my school years I often spent my holidays there. Some twenty years later, the illness of a near relative of mine afforded me an opportunity of seeing the place again. In a conversation with the doctor in charge of the place, who had attended my relative, I enquired about his dealings with the—I believe

—Slovakian peasants, who were his only *clients* during the winter. He told me that his medical treatment was carried on in the following way. In his consulting hours the patients came into his room and formed up in a line. One after another they came forward and told him their complaints. One of them might have pains in the back, or a stomach-ache, or a feeling of tiredness in the legs, etc. The doctor then examined him and, when he had formed his conclusions, told him the diagnosis, which was in every case the same. He translated the word to me, and what it amounted to was: "bewitched." I was astonished, and asked whether the patients made no objection to his saying the same thing to all of his patients. "Oh, no!" he answered, "they are very much pleased; it is exactly what they expect. Each one as he goes back to his place in the line says to the others by his looks and gestures: 'There's a fellow who knows what's what!'" At that time I little thought in what circumstances I should meet with an analogous situation.

For whether a person is a homosexual, or a necrophilist, or an anxiety-ridden hysteric, or a shut-in obsessional, or a raving madman—in every case the Individual Psychologist of the Adlerian persuasion will assign as the motive force of his condition the fact that he wants to assert himself, to over-compensate for his inferiority, to be on top, and to move over from the feminine to the masculine line. We used to hear exactly the same kind of thing when we were young students at the hospital. Hysterics, we were told, produce their symptoms in order to make themselves interesting and to attract attention to themselves. It is extraordinary how these old profundities recur! But even at the time this little bit of psychology did not seem to us to cover the problem of hysteria; it left unexplained, for instance, why people who suffer from it do not make use of some means for the attainment of their ends. Some element of this doctrine of the Individual Psychologists must, of course, be correct, though they regard this fragmentary explanation as a complete one. The instinct of self-preservation will attempt to turn every situation to its own account; the ego will try to get some advantage even out of being ill. In psycho-analysis we call this the *secondary gain from illness*. But indeed, when one thinks of the facts of masochism, of the unconscious need for punishment, and of the neurotic tendency to self-injury, all of which seem to imply the existence of instinctual impulses which run counter to self-preservation,

one comes to question even the general validity of the platitude on which the theoretical structure of Individual Psychology is built. But, to the mass of mankind, a theory like this must be exceedingly welcome, which takes no complications into account, which introduces no new and difficult concepts, which knows nothing of the unconscious, which removes at a single blow the problem of sexuality that weighs so heavily on everybody, and which confines itself to revealing the devices by means of which people try to make life comfortable. For the mass of mankind are themselves comfort-loving; they require only a single reason to serve as an explanation, they are not grateful to science for its intricacies, and they like to have simple answers given to their questions and to feel that their problems are settled once and for all. Once one sees how closely Individual Psychology approximates to the fulfilment of these requirements, one cannot help remembering a couplet from *Wallenstein*:

*If the idea were not so deuced clever,  
One might be tempted just to call it stupid.*

Specialist criticism, which has been so uncompromisingly opposed to psycho-analysis, has, in general, handled Individual Psychology with a velvet glove. It is, indeed, true that in America one of the most distinguished psychiatrists published a paper against Adler, entitled *Enough*, in which he gave strong expression to his dissatisfaction with the *repetition-compulsion* of the Individual Psychologists. If others have behaved far more kindly, the opposition to analysis is largely responsible.

I need not say much about other schools that have split off from us. That such splits have occurred is no argument for or against the truth of psycho-analysis. You have only to think of the strong emotional factors which make it difficult for many people to co-operate with others or adopt a subordinate position, and of the still greater difficulty which is embodied in the proverb: "*Quot capita tot sensus*."<sup>1</sup> When the differences of opinion had gone beyond a certain limit, the best thing to do was to part company, and thenceforward to go different ways, especially if the theoretical difference involved an alteration in analytical technique. Let us take, for example, an analyst who thinks very little of the influence of the patient's past, and looks for the cause of a neurosis exclusively in contemporary motives and expectations directed towards the future.

If that is so, he will also neglect the analysis of the patient's childhood and start on an altogether different technique; and he will have to make up for the absence of the effects of childhood-analysis by increasing his own didactic influence and by directly recommending the adoption of certain aims in life. We, for our part, would then say: "That may be a philosophy, but it is no longer analysis." Or another analyst may come to hold the view that the anxiety-experience of birth is the root of all later neurotic disturbances; in that case he may think it proper to restrict analysis to the effects of this one experience, and to promise therapeutic success after a three to four months' treatment. You will observe that I have chosen two examples which proceed from diametrically opposed premises. It is an almost universal characteristic of these *dissenting movements* that each of them seizes upon one fragment out of the wealth of motives found in psycho-analysis (such, for instance, as the instinct for the power, the ethical conflict, the mother, genitality, etc.), and, on the basis of this appropriation, makes itself independent. If it seems to you that such secessions are commoner today in the history of psycho-analysis than they are in any other movement of thought, I do not know whether I should agree with you. If it be so, we must attribute the responsibility to the close relationship between theoretical outlook and therapeutic practice, which is to be found in psycho-analysis. Mere differences of opinion would be borne with far longer. People like to accuse us psycho-analysts of intolerance. The only evidence of this disagreeable characteristic was precisely our separation from people who thought differently from ourselves. Apart from that, we have taken no steps against them; on the contrary, they are now in clover; they are far better off than before, because, in parting company with us, they have in most cases got rid of one of the burdens under which we groan—the odium of infantile sexuality, for instance, or the ludicrousness of symbolism—and they are now regarded by the world at large as, at all events, semi-respectable, which we, who remain behind, cannot even yet claim to be. It was they themselves, moreover, who—excepting for one noteworthy example—effected the separation.

And what more do you ask of us in the name of tolerance? When any one has expressed an opinion that we hold to be fundamentally false, do you wish us to speak to him like this?

<sup>1</sup> As many interpretations as heads.—Ed.

"Thank you so much for contradicting us. You have saved us from the danger of self-complacency, and have given us an opportunity of proving to the Americans that we really are as broadminded as they could possibly wish. We do not believe a word of what you say, but that does not matter. You are just as right as we are, in all probability. After all, who can ever know who is in the right? In spite of our disagreement, you must allow us to put forward your views in our publications. And we hope that you on your part will be so kind as to support ours although you disbelieve in them." This will obviously be the usage of the future in scientific circles, when the misapplication of Einstein's theory of relativity has completely won the day. It is true that, for the moment, we have not gone quite so far as that. We have confined ourselves, in the old-fashioned way, to putting forward only our own convictions; we expose ourselves to the danger of making mistakes, for no one can avoid that, and we reject anything that contradicts our views. As to the right to change our opinions, if we think we have found something better, we have made full use of it in psycho-analysis.

One of the first applications of psycho-analysis was that we were able to understand the opposition we had to meet on account of our psycho-analytic activities. Other applications, of an objective nature, can lay claim to a more general interest. Our first intention was, as you know, to understand the disturbances of the human mind, because an astonishing experience had shown us that in this case understanding and cure go almost hand in hand and that a practicable path leads from the one to the other. And for a long time this was our only intention. Then, however, we came to recognize the close relationship, in fact, the underlying identity, subsisting between pathological and so-called normal processes. So psycho-analysis became *depth-psychology*; and, since nothing that man makes or does can be understood without the aid of psychology, the applications of psycho-analysis to numerous fields of knowledge, and especially to the mental sciences, came about automatically, forced themselves on our attention and demanded elaboration. Unluckily, the tasks which we now undertook brought us up against obstacles, which, lying as they do in the very nature of the situation, have not yet been overcome. Such an application presupposes a technical knowledge which the analyst does not possess; while those who do possess the knowledge—the ex-

perts—do not know anything of analysis, and perhaps do not want to know anything. The result has been that analysts have entered the lists in such fields as those of mythology, the history of civilization, ethnology, the science of religion, etc., as amateurs, with a more or less adequate equipment, often collected in a hurry. In those fields they were treated by the specialists, who were established there, as no better than interlopers; and their methods, as well as their findings, in so far as they attracted any attention at all, were, to begin with, rejected. But the position is steadily improving; in every field, the number of people who study psycho-analysis with a view to making use of it in their special researches is growing, in the same way that colonists take the place of pioneers. Here we may expect a rich harvest of new knowledge. Applications of psycho-analysis are always confirmations of it as well. In regions where scientific work is more remote from practical activity, the inevitable differences of opinion will be less embittered.

I feel greatly tempted to take you through all the applications of psycho-analysis in the field of mental science. There are things which every one who has intellectual interests would think worth knowing, and to hear no more for a time about abnormalities and illness would give us a well-earned relief. But I must resist the temptation; it would once more take us too far outside the framework of these lectures, and, to tell you the truth, I should not be competent to do it. It is true that I took the first step along some of these lines, but today I no longer command a view over the whole field, and I should have to spend much time in study in order to grasp all that has been added since I made my first attempts. Those of you who are disappointed by my refusal can make up for it by reading our journal, *Imago*, which is devoted to the non-medical applications of analysis.

There is one subject, however, that I cannot pass by so easily, though this is not because I have any special understanding of it or have done much work on it myself. On the contrary, I have hardly ever occupied myself with it. But it is of immense importance, and rich in hopes for the future; perhaps, indeed, it is the most important of all the activities of analysis. I refer to the application of psycho-analysis to education, to the up-bringing of the next generation. I am at least glad to be able to say that my daughter, Anna Freud, has made this her life-work, and is in this way making good my

own neglect of the subject. One can easily see the path that has led to this application of analysis. When, during the treatment of an adult neurotic, we tried to trace the determination of his symptoms, we were always led back into his early childhood. A knowledge of the later aetiological factors was not sufficient either for our understanding of his condition or to effect a cure. The result was that we were forced to acquaint ourselves with the psychological peculiarities of the years of infancy; and we learned a great many things which could not have been discovered except through analysis, and were in a position to set right a number of generally accepted beliefs about childhood. We came to see that the first years of infancy (up to about the age of five) are, for a number of reasons, of special importance. This is, in the first place, because they contain the first expansion of sexuality, which leaves behind decisive determinants for the sexual life of maturity; and, in the second place, because the impressions of this period come up against an unformed and weak ego, upon which they act like traumas. The ego cannot defend itself against the emotional storms which they call forth except by repression, and in this way it acquires in childhood all its predispositions to subsequent illnesses and disturbances of function. We have come to realize that the difficulty of childhood consists in the fact that the child has, in a short span of time, to make its own the acquisitions of a cultural development which has extended over tens of thousands of years; it has, that is, to attain instinctual control and social adaptation, or, at any rate, their first elements. It can only achieve a part of this alteration through its own development; a great deal must be forced upon it by education. We are not in the least surprised that the child often performs its task only incompletely. A great many children in these early years pass through conditions which may be compared with neuroses, and this is certainly true of all those who develop a manifest illness later on. In not a few cases the neurotic illness does not wait till they are grown up, but breaks out in childhood and is a source of great trouble to parents and doctors.

We have had no hesitation in applying analytic therapy to such children as either display unambiguous neurotic symptoms, or are on the way to an unfavourable character-development. The anxiety expressed by opponents of analysis, that the child might be harmed by the process, has turned out to be quite unfounded.

The advantage gained by this procedure is that we have been able to confirm in the living subject what we have only inferred, as though from historical documents, in the case of adults. But the advantages gained by the children themselves was most satisfactory. It turned out that the child is a most favourable subject for analytic therapy; successes were radical and permanent. Naturally, one has to make extensive alterations in the technique of treatment which has been developed for adults when one is dealing with children. The child is, psychologically, a different thing from the adult; it does not yet possess a super-ego, it cannot make much use of the method of free association, and transference plays a different part with it, since its real parents are still there. The internal resistances, against which we have to fight in the case of adults, are in the case of children for the most part replaced by external difficulties. If the parents make themselves into vehicles for the resistance, the aims of the analysis and even the process of the analysis itself, are often endangered. For this reason, it is often necessary to combine a certain amount of analytic influencing of the parents with the analysis of the children. On the other hand, the inevitable differences between child analysis and adult analysis are diminished by the fact that many of our patients have still kept so many of their infantile characteristics that the analyst, once more adapting himself to his patient, cannot avoid making use of certain parts of the technique of child analysis in their case too. It is in the nature of things that child analysis should have become the special field of women analysts, and this will no doubt continue to be so.

The view that the majority of our children pass through a neurotic phase in the course of their development automatically raises a hygienic question. It may be asked whether it would not be advantageous to come to the aid of a child with analysis even where there is no sign of a disturbance, as a precautionary measure in the interests of its health, just as nowadays one inoculates healthy children against diphtheria, without waiting for them to fall ill of the disease. The discussion of this question is today only a matter of academic interest. I can venture to speak about it to you; but the greater number of our contemporaries would regard the mere idea as nothing short of criminal, and, when one considers the attitude of most parents towards analysis, one must, as yet, give up any hope of its realization. Such

a prophylactic against nervous disease, which would probably be very effective, presupposes an entirely different structure of society. The application of psycho-analysis to education must be looked for today in quite a different direction. Let us get a clear idea of what the primary business of education is. The child has to learn to control its instincts. To grant it complete freedom, so that it obeys all its impulses without any restriction, is impossible. It would be a very instructive experiment for child-psychologists, but it would make life impossible for the parents and would do serious damage to the children themselves, as would be seen partly at the time, and partly during subsequent years. The function of education, therefore, is to inhibit, forbid, and suppress, and it has at all times carried out this function to admiration. But we have learnt from analysis that it is this very suppression of instincts that involves the danger of neurotic illness. You will remember that we have gone into the question of how this comes about in some detail. Education has therefore to steer its way between the Scylla of giving the instincts free play and the Charybdis of frustrating them. Unless the problem is altogether insoluble, an optimum of education must be discovered, which will do the most good and the least harm. It is a matter of finding out how much one may forbid, at which times, and by what methods. And then it must further be considered that the children have very different constitutional dispositions, so that the same educational procedure cannot possibly be equally good for all children. A moment's consideration will show us that, so far, education has fulfilled its function very badly, and has done children serious injury. If we can find an optimum of education which will carry out its task ideally, then we may hope to abolish one of the factors in the aetiology of neurotic illness, viz., the influence of accidental infantile traumas. The other factor, the power of a refractory instinctual constitution, can never be got rid of by education. When, therefore, one comes to think of the difficult tasks with which the educator is confronted; when one reflects that he has to recognize the characteristic constitution of each child, to guess from small indications what is going on in its unformed mind, to give him the right amount of love and at the same time to preserve an effective degree of authority, then one cannot help saying to oneself that the only adequate preparation for the profession of educator is a good grounding in psycho-anal-

ysis. The best thing would be for him to be analysed himself, for, after all, without personal experience one cannot get a grasp of analysis. The analysis of teachers and educators seems to be a more practicable prophylactic measure than the analysis of children themselves; and there are not such great obstacles against putting it into practice.

I will only mention, in passing, an indirect advantage which analysis may bring to the education of children, an advantage which may eventually come to have considerable importance. Parents who have experienced an analysis themselves, and who have derived much benefit from it, among other things an insight into the mistakes in their own upbringing, will treat their children with better understanding, and will spare them a great deal which they were not spared themselves. Parallel with the efforts of the analyst to influence education, run other investigations into the cause and prevention of delinquency and criminology. Here again I shall only open the door and show you what lies behind it, but I shall not take you inside. If your interest in psycho-analysis is maintained, you will be able to learn a great deal that is both new and valuable on these subjects. I cannot, however, leave the theme of education without mentioning one particular point of view. It has been said—and no doubt with justice—that every education is partisan; it aims at making the child adapt itself to whatever social system is the established one, without consideration of how valuable or how stable that system may be. If, it is argued, one is convinced of the shortcomings of our present-day social arrangements, one cannot think it right to give them the added support of this psycho-analytical education of ours. We must place before it another and a higher aim, one which is emancipated from the social standards that are dominant today. I do not feel, however, that this argument is valid. It is demanding more of analysis than its functions can justify. The physician who is called in to treat a case of pneumonia has no need to consider whether the patient is a good man, a suicide, or a criminal; whether he deserves to remain alive, or whether it is for his advantage to do so. This other aim which it is sought to place before education would be a partisan one as well, and it is not the business of the analyst to decide between parties. I am not now considering the fact that people will refuse to allow psycho-analysis to have any influence at all on education if it confesses to aims which are in-

compatible with the existing social order. Psycho-analytic education will be assuming an unwarranted responsibility if it sets out to make its pupils into revolutionaries. It will have done its task if it sends them away as healthy and as efficient as possible. There are enough revolutionary elements contained within itself to ensure that no one brought up under its influence will in later life be on the side of reaction and suppression. I should go so far as to say that revolutionary children are not desirable from any point of view.

Ladies and Gentlemen—I shall conclude by saying a few words on the therapeutic aspect of psycho-analysis. I discussed the theoretical side of the subject fifteen years ago, and I cannot formulate it in any other way today; but I will say something about the practical experience which we have had with it during the interval. You know, of course, that psycho-analysis originated as a therapeutic procedure; it has gone far beyond that, but it has never given up its original field of work, and it still relies upon contact with clinical material for its further advances and development. The accumulation of empirical data upon which we base our theories can be obtained in no other way. Our therapeutic failures are constantly setting us new tasks, and the requirements of real life are an efficient protection against carrying to excess the speculation which we, nevertheless, cannot avoid in our work. I have already, in my former lectures, given an account of the means by which psycho-analysis helps the patient, and along what lines; today we will consider to what extent it succeeds.

You are perhaps aware that I have never been a therapeutic enthusiast; and there is no danger of my using this as an opportunity for ringing the praises of analysis in this respect. I would rather say too little than too much. At a time when I was still the only analyst, people who were apparently kindly disposed to my opinions used to say to me: "That is all very nice and clever; but show me a case that you have cured by analysis." This was one of the many formulas that succeeded one another, as time went on, whose function it was to put the inconvenient novelty on one side. Today it is as out of date as many others; the analyst, like any other therapist, has his collection of letters of gratitude from patients who have been cured. And the analogy does not end there. Psycho-analysis really is a form of therapy, just as other methods are. It has its tri-

umphs, its defeats, its difficulties, its limitations, and its indications. There was a time when people attacked analysis with the accusation that it was not to be taken seriously as a therapy, because it did not venture to publish any statistics of its successes. Since then, the Institute of Psycho-Analysis in Berlin, which was founded by Dr. Max Eitingon, has published a report of its work during the first ten years of its existence. The proportion of recoveries which have been effected give us ground neither for boasting nor for feeling ashamed. But such statistics are not instructive, because the material with which they deal is so heterogeneous that it would need a very large number of cases to prove anything. It is better to examine one's own individual experience. As to that, I may say that I do not think our successes can compete with those of Lourdes. There are so many more people who believe in the miracles of the Blessed Virgin than in the existence of the unconscious. But if we disregard supernatural competition, we must compare psycho-analysis with other methods of psycho-therapy. Nowadays one need hardly take into consideration organic physical treatment of neurotic conditions. As a psycho-therapeutic method, analysis does not stand in opposition to other methods employed in this branch of medicine; it does not invalidate them nor does it exclude them. There would be no theoretical objection to a physician who described himself as a psycho-therapist using analysis upon his patients alongside other therapeutic methods, according to the peculiar character of the case and the favourable or unfavourable nature of the circumstances. In actual fact, it is the question of technique which renders necessary the specialization of medical practice. So, for example, it became necessary to separate surgery and orthopaedics. The practice of psycho-analysis is difficult and exacting! It cannot well be dealt with like a pair of spectacles, which can be put on for reading and taken off when one wants to go for a walk. As a rule, psycho-analysis either possesses the doctor entirely or not at all. The psycho-therapists who occasionally make use of analysis do not, as far as my experience goes, stand on a firm analytical basis; they have not accepted analysis as a whole, but have watered it down, and perhaps removed its sting; they cannot be counted as analysts. In my opinion this is to be regretted; but a co-operation in medical practice between an analyst and a psycho-therapist who limits him-

self to other methods, would be altogether advantageous.

Compared with other psycho-therapeutic procedures, psycho-analysis is far and away the most powerful. That is quite as it should be, since it costs the most trouble and time, and one would not make use of it for slight cases; in suitable cases, one can remove disturbances and bring about alterations which could not be hoped for in pre-analytic times. But it has also perfectly clearly felt limitations. The therapeutic ambitions of many of my followers have led them to be at great pains to remove such hindrances, so that all neurotic disturbances might be curable by means of psycho-analysis. They have attempted to compress the work of analysis into a shorter period, to intensify the transference so that it should be superior to any resistance, and to combine other methods of influence with analysis in order to obtain a cure. These enterprises are no doubt praiseworthy, but in my opinion they are in vain. They also involve the danger of oneself being drawn away from analysis and of drifting into a boundless sea of experimentation. The expectation that we shall be able to cure all neurotic symptoms is, I suspect, derived from the lay belief that neuroses are entirely superfluous things which have no right whatever to exist. As a matter of fact, they are serious, constitutionally determined affections, which are seldom restricted to a few outbreaks, but make themselves felt as a rule over long periods of life, or even throughout its entire extent. Our analytic experience that we can influence them to a far-reaching degree, if we can get hold of the historical precipitating causes and the incidental accessory factors, has made us neglect the constitutional factor in our therapeutic practice. And we are in fact powerless to deal with it; but in our theory we ought always to bear it in mind. In any case, the complete inaccessibility of the psychoses to analytic therapy should, in view of their close relationship to the neuroses, moderate our optimism in regard to the latter. The therapeutic efficiency of psycho-analysis is limited by a whole series of important factors, which can scarcely be dealt with at all. With children, where one might hope to have the greatest successes, there are the external difficulties of the parental situation; yet, after all, these are bound up with the very fact of being a child. With adults we are primarily concerned with two factors, the degree of their mental rigidity and the form of their disease with all the deeper-

seated determinants that lie behind it. The former of these is often unjustifiably overlooked. However great the plasticity of mental life may be, and however great the possibility of reviving past states, not everything can be brought to life again. A great many alterations seem final, and correspond to scars left behind by processes which have run their course. In other cases one gets an impression of a general rigidity of the whole mind; mental processes, which one could very well redirect into other channels, seem incapable of leaving their old courses. But perhaps this is the same as what we have said already, but looked at from another point of view. Only too often one seems to see that the therapeutic process is merely lacking in the necessary motive force to enable it to bring about the alteration. Some specific tendency, some particular instinctual component, is too strong in comparison with the counter-forces that we can mobilize against it. This is quite generally so in the case of the psychoses. We understand them in so far as we know quite well where we ought to apply the levers, but they are not able to lift the weight. In this connection we may hope that in the future our knowledge of the action of hormones—you know, of course, what they are—will provide us with a means of coping successfully with the quantitative factors involved in these diseases; but today we are far from having reached that desirable goal. I can understand that the uncertainty prevailing in all these matters is a constant incentive towards perfecting the technique of analysis, especially in the matter of the transference. The beginner in analysis, in particular, will be in doubt, when he is unsuccessful, whether he ought to blame the peculiarity of the case or his own unskilful handling of the therapeutic procedure. But, as I have said already, I do not think that there is much to be gained by directing one's energies along these channels.

The other limitation to analytical successes is imposed by the form of the disease. You know already that the field in which analytical therapy can be applied is that of the transference-neuroses, phobias, hysterias, obsessional neuroses, and, besides these, such abnormalities of character as have been developed instead of these diseases. Everything other than these, such as narcissistic or psychotic conditions, is more or less unsuitable. Now it would be perfectly legitimate to save oneself from failures by carefully excluding such cases. If this precaution were taken, the statistics of analysis

would be very much improved. Yes; but this is not so easy as it seems. Our diagnoses can very often only be made *ex post facto*. They are like the test for witch-finding applied by the Scottish king, of which I have read in one of Victor Hugo's books. This king declared that he had an infallible method for detecting witches. He put them to simmer in a cauldron of boiling water, and then tasted the soup. According to the taste he could say "that was a witch," or "that was not a witch." The same thing happens with us, except that it is we who are the sufferers. We cannot give an opinion about a patient who comes for treatment, or a candidate for training, until we have studied him analytically for some weeks or months. We are, in fact, always buying a pig in a poke. The subject comes to us with undefined, general troubles which do not allow of any certain diagnosis. After a period of probation, it may turn out that the case is an unsuitable one. Then, if he is a candidate, we send him away; or, if he is a patient, we keep him on a little while to see whether we cannot take a more favourable view of him. The patient has his revenge by swelling our list of failures, and the rejected candidate, it may be (if he is paranoid), by writing psycho-analytical books himself. You will observe that our caution has not been of much value to us.

I am afraid these details will have gone beyond the scope of your interests. But I should be even more distressed if you were to think that I intend to diminish your respect for psycho-analysis as a therapeutic procedure. Perhaps I have really set about the business clumsily. I wanted, you see, to achieve the opposite: to excuse the therapeutic limitations of analysis by indicating how unavoidable they are. With the same object in view, let me turn to another point, namely the complaint that analytic treatment takes up a disproportionately long time. The answer to that is that psychological changes only come about very slowly; if they occur quickly and suddenly it is a bad sign. It is true that the treatment of a serious neurosis may easily last several years, but, if a successful result is achieved, you must ask yourselves how long the illness itself would otherwise have lasted. It would probably have lasted a decade for every year of treatment, which means that the illness would never have passed off at all, as we so often find in untreated cases. In many instances we have reasons for resuming an analysis after an interval of many years; new events in the patient's life

have called out in him new pathological reactions, though in the meantime he has been perfectly healthy. The first analysis had not actually brought all his pathological dispositions to the surface, and it was natural that the analysis should have been broken off as soon as it was successful. There are also people who are so seriously afflicted that they have to be kept under analytic care throughout their whole lives and taken back into analysis from time to time; but such people would otherwise be incapable of carrying on their lives at all, and one must be thankful that they can be kept going by means of this intermittent and recurrent treatment. The analysis of characterological disturbances, too, involves a lengthy treatment but it is often successful; and it may be asked whether there is any other form of treatment that could even attempt to deal with this problem. Therapeutic ambition may make us feel unsatisfied with these results, but after all we have the examples of tuberculosis and lupus before us, which teach us that one can only meet with success if the treatment is adapted to the character of the disease.

I have told you that psycho-analysis began as a therapeutic procedure, but it is not in that light that I wanted to recommend it to your interest, but because of the truths it contains, because of the information it gives us about that which is of the greatest importance to mankind, namely his own nature, and because of the connections it has shown to exist between the most various of his activities. As a form of therapy it is one among many, though certainly *prima inter pares*.<sup>1</sup> If it had no therapeutic value, it would not have been discovered from clinical material and would not have continued to develop for more than thirty years.

## LECTURE 35

### A PHILOSOPHY OF LIFE

LADIES AND GENTLEMEN: In the last lecture we were occupied with trivial everyday affairs, with putting, as it were, our modest house in order. We will now take a bold step, and risk an answer to a question which has repeatedly been raised in non-analytic quarters, namely, the question whether psycho-analysis leads to any particular *Weltanschauung*, and if so, to what.

*Weltanschauung* is, I am afraid, a specifically German notion, which it would be difficult to

<sup>1</sup> Chief among equals.—Ed.

translate into a foreign language. If I attempt to give you a definition of the word, it can hardly fail to strike you as inept. By *Weltanschauung*, then, I mean an intellectual construction, which gives a unified solution of all the problems of our existence in virtue of a comprehensive hypothesis, a construction, therefore, in which no question is left open and in which everything in which we are interested finds a place. It is easy to see that the possession of such a *Weltanschauung* is one of the ideal wishes of mankind. When one believes in such a thing, one feels secure in life, one knows what one ought to strive after, and how one ought to organize one's emotions and interests to the best purpose.

If that is what is meant by a *Weltanschauung*, then the question is an easy one for psycho-analysis to answer. As a specialized science, a branch of psychology—depth-psychology or psychology of the unconscious—it is quite unsuited to form a *Weltanschauung* of its own; it must accept that of science in general. The scientific *Weltanschauung* is, however, markedly at variance with our definition. The *unified* nature of the explanation of the universe is, it is true, accepted by science, but only as a program whose fulfilment is postponed to the future. Otherwise it is distinguished by negative characteristics, by a limitation to what is, at any given time, knowable, and a categorical rejection of certain elements which are alien to it. It asserts that there is no other source of knowledge of the universe, but the intellectual manipulation of carefully verified observations, in fact, what is called *research*, and that no knowledge can be obtained from revelation, intuition, or inspiration. It appears that this way of looking at things came very near to receiving general acceptance during the last century or two. It has been reserved for the present century to raise the objection that such a *Weltanschauung* is both empty and unsatisfying, that it overlooks all the spiritual demands of man, and all the needs of the human mind.

This objection cannot be too strongly repudiated. It cannot be supported for a moment, for the spirit and the mind are the subject of scientific investigation in exactly the same way as any non-human entities. Psycho-analysis has a peculiar right to speak on behalf of the scientific *Weltanschauung* in this connection, because it cannot be accused of neglecting the part occupied by the mind in the universe. The contribution of psycho-analysis to science con-

sists precisely in having extended research to the region of the mind. Certainly without such a psychology, science would be very incomplete. But if we add to science the investigation of the intellectual and emotional functions of men (and animals), we find that nothing has been altered as regards the general position of science, that there are no new sources of knowledge or methods of research. Intuition and inspiration would be such, if they existed; but they can safely be counted as illusions, as fulfilments of wishes. It is easy to see, moreover, that the qualities which, as we have shown, are expected of a *Weltanschauung* have a purely emotional basis. Science takes account of the fact that the mind of man creates such demands and is ready to trace their source, but it has not the slightest ground for thinking them justified. On the contrary, it does well to distinguish carefully between illusion (the results of emotional demands of that kind) and knowledge.

This does not at all imply that we need push these wishes contemptuously aside, or underestimate their value in the lives of human beings. We are prepared to take notice of the fulfilments they have achieved for themselves in the creations of art and in the systems of religion and philosophy; but we cannot overlook the fact that it would be wrong and highly inexpedient to allow such things to be carried over into the domain of knowledge. For in that way one would open the door which gives access to the region of the psychoses, whether individual or group psychoses, and one would drain off from these tendencies valuable energy which is directed towards reality and which seeks by means of reality to satisfy wishes and needs as far as this is possible.

From the point of view of science we must necessarily make use of our critical powers in this direction, and not be afraid to reject and deny. It is inadmissible to declare that science is one field of human intellectual activity, and that religion and philosophy are others, at least as valuable, and that science has no business to interfere with the other two, that they all have an equal claim to truth, and that every one is free to choose whence he shall draw his convictions and in what he shall place his belief. Such an attitude is considered particularly respectable, tolerant, broad-minded, and free from narrow prejudices. Unfortunately it is not tenable; it shares all the pernicious qualities of an entirely unscientific *Weltanschauung* and in practice comes to much the same thing. The

bare fact is that truth cannot be tolerant and cannot admit compromise or limitations, that scientific research looks on the whole field of human activity as its own, and must adopt an uncompromisingly critical attitude towards any other power that seeks to usurp any part of its province.

Of the three forces which can dispute the position of science, religion alone is a really serious enemy. Art is almost always harmless and beneficent, it does not seek to be anything else but an illusion. Save in the case of a few people who are, one might say, obsessed by Art, it never dares to make any attacks on the realm of reality. Philosophy is not opposed to science; it behaves itself as if it were a science, and to a certain extent it makes use of the same methods; but it parts company with science, in that it clings to the illusion that it can produce a complete and coherent picture of the universe, though in fact that picture must needs fall to pieces with every new advance in our knowledge. Its methodological error lies in the fact that it over-estimates the epistemological value of our logical operations, and to a certain extent admits the validity of other sources of knowledge, such as intuition. And often enough one feels that the poet Heine is not unjustified when he says of the philosopher:

*With his night-cap and his night-shirt tatters,  
He botches up the loop-holes in the structure of  
the world.*

But philosophy has no immediate influence on the great majority of mankind; it interests only a small number even of the thin upper stratum of intellectuals, while all the rest find it beyond them. In contradistinction to philosophy, religion is a tremendous force, which exerts its power over the strongest emotions of human beings. As we know, at one time it included everything that played any part in the mental life of mankind, that it took the place of science, when as yet science hardly existed, and that it built up a *Weltanschauung* of incomparable consistency and coherence which, although it has been severely shaken, has lasted to this day.

If one wishes to form a true estimate of the full grandeur of religion, one must keep in mind what it undertakes to do for men. It gives them information about the source and origin of the universe, it assures them of protection and final happiness amid the changing vicissitudes of life, and it guides their thoughts

and actions by means of precepts which are backed by the whole force of its authority. It fulfils, therefore, three functions. In the first place, it satisfies man's desire for knowledge; it is here doing the same thing that science attempts to accomplish by its own methods, and here, therefore, enters into rivalry with it. It is to the second function that it performs, that religion no doubt owes the greater part of its influence. In so far as religion brushes away men's fear of the dangers and vicissitudes of life, in so far as it assures them of a happy ending, and comforts them in their misfortunes, science cannot compete with it. Science, it is true, teaches how one can avoid certain dangers and how one can combat many sufferings with success; it would be quite untrue to deny that science is a powerful aid to human beings, but in many cases it has to leave them to their suffering, and can only advise them to submit to the inevitable. In the performance of its third function, the provision of precepts, prohibitions, and restrictions, religion is furthest removed from science. For science is content with discovering and stating the facts. It is true that, from the applications of science, rules and recommendations for behaviour may be deduced. In certain circumstances they may be the same as those which are laid down by religion, but even so the reasons for them will be different.

It is not quite clear why religion should combine these three functions. What has the explanation of the origin of the universe to do with the inculcation of certain ethical precepts? Its assurances of protection and happiness are more closely connected with these precepts. They are the reward for the fulfilment of the commands; only he who obeys them can count on receiving these benefits, while punishment awaits the disobedient. For the matter of that, something of the same kind applies to science; for it declares that any one who disregards its inferences is liable to suffer for it.

One can only understand this remarkable combination of teaching, consolation, and precept in religion, if one subjects it to genetic analysis. We may begin with the most remarkable item of the three, the teaching about the origin of the universe—for why should a cosmogony be a regular element of religious systems? The doctrine is that the universe was created by a being similar to man, but greater in every respect, in power, wisdom, and strength of passion, in fact by an idealized superman.

Where you have animals as creators of the universe, you have indications of the influence of Totemism, which I shall touch on later, at any rate with a brief remark. It is interesting to notice that this creator of the universe is always a single god, even when many gods are believed in. Equally interesting is the fact that the creator is nearly always a male, although there is no lack of indication of the existence of female deities and many mythologies make the creation of the world begin precisely with a male god triumphing over a female goddess, who is degraded into a monster. This raises the most fascinating minor problems, but we must hurry on. The rest of our enquiry is made easy because this God-Creator is openly called Father. Psycho-analysis concludes that he really is the father, clothed in the grandeur in which he once appeared to the small child. The religious man's picture of the creation of the universe is the same as his picture of his own creation.

If this is so, then it is easy to understand how it is that the comforting promises of protection and the severe ethical commands are found together with the cosmogony. For the same individual, to whom the child owes its own existence, the father (or, more correctly, the parental function which is composed of the father and the mother), has protected and watched over the weak and helpless child, exposed as it is to all the dangers which threaten in the external world; in its father's care it has felt itself safe. Even the grown man, though he may know that he possesses greater strength, and though he has greater insight into the dangers of life, rightly feels that fundamentally he is just as helpless and unprotected as he was in childhood and that in relation to the external world he is still a child. Even now, therefore, he cannot give up the protection which he has enjoyed as a child. But he has long ago realized that his father is a being with strictly limited powers and by no means endowed with every desirable attribute. He therefore looks back to the memory-image of the overrated father of his childhood, exalts it into a deity, and brings it into the present and into reality. The emotional strength of this memory-image and the lasting nature of his need for protection are the two supports of his belief in God.

The third main point of the religious program, its ethical precepts, can also be related without any difficulty to the situation of childhood. In a famous passage, which I have already quoted in an earlier lecture, the philoso-

pher Kant speaks of the starry heaven above us and the moral law within us as the strongest evidence for the greatness of God. However odd it may sound to put these two side by side—for what can the heavenly bodies have to do with the question whether one man loves another or kills him?—nevertheless it touches on a great psychological truth. The same father (the parental function) who gave the child his life and preserved it from the dangers which that life involves, also taught it what it may or may not do, made it accept certain limitations of its instinctual wishes, and told it what consideration it would be expected to show towards its parents and brothers and sisters, if it wanted to be tolerated and liked as a member of the family circle, and later on of more extensive groups. The child is brought up to know its social duties by means of a system of love-rewards and punishments, and in this way it is taught that its security in life depends on its parents (and, subsequently, other people) loving it and being able to believe in its love for them. This whole state of affairs is carried over by the grown man unaltered into his religion. The prohibitions and commands of his parents live on in his breast as his moral conscience; God rules the world of men with the help of the same system of rewards and punishments, and the degree of protection and happiness which each individual enjoys, depends on his fulfilment of the demands of morality; the feeling of security, with which he fortifies himself against the dangers both of the external world and of his human environment, is founded on his love of God and the consciousness of God's love for him. Finally, he has in prayer a direct influence on the divine will, and in that way insures for himself a share in the divine omnipotence.

I am sure that while you have been listening to me, a whole host of questions must have come into your minds which you would like to have answered. I cannot undertake to do so here and now, but I am perfectly certain that none of these questions of detail would shake our thesis that the religious *Weltanschauung* is determined by the situation that subsisted in our childhood. It is therefore all the more remarkable that, in spite of its infantile character, it nevertheless has a forerunner. There was, without doubt, a time when there were no religions and no gods. It is known as the *age of animism*. Even at that time the world was full of spirits in the semblance of men (demons, as we call them), and all the objects in the ex-

ternal world were their dwelling-place or perhaps identical with them, but there was no supreme power which had created them all, which controlled them, and to which it was possible to turn for protection and aid. The demons of animism were usually hostile to man, but it seems as though man had more confidence in himself in those days than later on. He was no doubt in constant terror of these evil spirits, but he defended himself against them by means of certain actions to which he ascribed the power to drive them away. Nor did he think himself entirely powerless in other ways. If he wanted something from nature—rain, for instance—he did not direct a prayer to the weather-god, but used a spell, by means of which he expected to exert a direct influence over nature; he himself made something which resembled rain. In his fight against the powers of the surrounding world, his first weapon was magic, the first forerunner of our modern technology. We suppose that this confidence in magic is derived from the overestimation of the individual's own intellectual operations, from the belief in the *omnipotence of thoughts*, which, incidentally, we come across again in our obsessional neurotics. We may imagine that the men of that time were particularly proud of their acquisition of speech, which must have been accompanied by a great facilitation of thought. They attributed magic power to the spoken word. This feature was later on taken over by religion. "And God said: Let there be light, and there was light." But the fact of magic actions shows that animistic man did not rely entirely on the force of his own wishes. On the contrary, he depended for success upon the performance of an action, which would cause Nature to imitate it. If he wanted it to rain, he himself poured out water; if he wanted to stimulate the soil to fertility, he offered it a performance of sexual intercourse in the fields.

You know how tenaciously anything that has once found psychological expression persists. You will, therefore, not be surprised to hear that a great many manifestations of animism have lasted up to the present day, mostly as what are called *superstitions*, side by side with and behind religion. But more than that, you can hardly avoid coming to the conclusion that our philosophy has preserved essential traits of animistic modes of thought, such as the overestimation of the magic of words and the belief that real processes in the external world follow the lines laid down by our thoughts. It

is, to be sure, an animism without magical practices. On the other hand we should expect to find that in the age of animism there must already have been some kind of morality, some rules governing the intercourse of men with one another. But there is no evidence that they were closely bound up with animistic beliefs. Probably they were the immediate expression of the distribution of power and of practical necessities.

It would be very interesting to know what determined the transition from animism to religion; but you may imagine in what darkness this earliest epoch in the evolution of the human mind is still shrouded. It seems to be a fact that the earliest form in which religion appeared was the remarkable one of totemism, the worship of animals, in the train of which followed the first ethical commands, the taboos. In a book called *Totem and Taboo*, I once worked out a suggestion, in accordance with which this change is to be traced back to an upheaval in the relationships in the human family. The main achievement of religion, as compared with animism, lies in the psychic binding of the fear of demons. Nevertheless, the evil spirit still has a place in the religious system as a relic of the previous age.

So much for the pre-history of the religious *Weltanschauung*. Let us now turn to consider what has happened since, and what is still going on under our own eyes. The scientific spirit, strengthened by the observation of natural processes, began in the course of time to treat religion as a human matter, and to subject it to a critical examination. This test it failed to pass. In the first place, the accounts of miracles roused a feeling of surprise and disbelief, since they contradicted everything that sober observation had taught, and betrayed all too clearly the influence of human imagination. In the next place, its account of the nature of the universe had to be rejected, because it showed evidence of a lack of knowledge which bore the stamp of earlier days, and because, owing to increasing familiarity with the laws of nature, it had lost its authority. The idea that the universe came into being through an act of generation or creation, analogous to that which produces an individual human being, no longer seemed to be the most obvious and self-evident hypothesis; for the distinction between living and sentient beings and inanimate nature had become apparent to the human mind, and had made it impossible to retain the original animistic theory. Besides this, one must not over-

look the influence of the comparative study of different religious systems, and the impression they give of mutual exclusiveness and intolerance.

Fortified by these preliminary efforts, the scientific spirit at last summoned up courage to put to the test the most important and the most emotionally significant elements of the religious *Weltanschauung*. The truth could have been seen at any time, but it was long before any one dared to say it aloud: the assertions made by religion that it could give protection and happiness to men, if they would only fulfil certain ethical obligations, were unworthy of belief. It seems not to be true that there is a power in the universe, which watches over the well-being of every individual with parental care and brings all his concerns to a happy ending. On the contrary, the destinies of man are incompatible with a universal principle of benevolence or with—what is to some degree contradictory—a universal principle of justice. Earthquakes, floods, and fires do not differentiate between the good and devout man, and the sinner and unbeliever. And, even if we leave inanimate nature out of account and consider the destinies of individual men in so far as they depend on their relations with others of their own kind, it is by no means the rule that virtue is rewarded and wickedness punished, but it happens often enough that the violent, the crafty, and the unprincipled seize the desirable goods of the earth for themselves, while the pious go empty away. Dark, unfeeling, and unloving powers determine human destiny; the system of rewards and punishments, which, according to religion, governs the world, seems to have no existence. This is another occasion for abandoning a portion of the animism which has found refuge in religion.

The last contribution to the criticism of the religious *Weltanschauung* has been made by psycho-analysis, which has traced the origin of religion to the helplessness of childhood, and its content to the persistence of the wishes and needs of childhood into maturity. This does not precisely imply a refutation of religion, but it is a necessary rounding off of our knowledge about it, and, at least on one point, it actually contradicts it, for religion lays claim to a divine origin. This claim, to be sure, is not false if our interpretation of God is accepted.

The final judgment of science on the religious *Weltanschauung*, then, runs as follows. While the different religions wrangle with one another as to which of them is in possession of the

truth, in our view the truth of religion may be altogether disregarded. Religion is an attempt to get control over the sensory world, in which we are placed, by means of the wish-world, which we have developed inside us as a result of biological and psychological necessities. But it cannot achieve its end. Its doctrines carry with them the stamp of the times in which they originated, the ignorant childhood days of the human race. Its consolations deserve no trust. Experience teaches us that the world is not a nursery. The ethical commands, to which religion seeks to lend its weight, require some other foundations instead, for human society cannot do without them, and it is dangerous to link up obedience to them with religious belief. If one attempts to assign to religion its place in man's evolution, it seems not so much to be a lasting acquisition, as a parallel to the neurosis which the civilized individual must pass through on his way from childhood to maturity.

You are, of course, perfectly free to criticise this account of mine, and I am prepared to meet you half way. What I have said about the gradual crumbling of the religious *Weltanschauung* was no doubt an incomplete abridgement of the whole story; the order of the separate events was not quite correctly given, and the co-operation of various forces towards the awakening of the scientific spirit was not traced. I have also left out of account the alterations which occurred in the religious *Weltanschauung* itself, both during the period of its unchallenged authority and afterwards under the influence of awakening criticism. Finally I have, strictly speaking, limited my remarks to one single form of religion, that of the Western peoples. I have, as it were, constructed a lay-figure for the purposes of a demonstration which I desired to be as rapid and as impressive as possible. Let us leave on one side the question of whether my knowledge would in any case have been sufficient to enable me to do it better or more completely. I am aware that you can find all that I have said elsewhere, and find it better said; none of it is new. But I am firmly convinced that the most careful elaboration of the material upon which the problems of religion are based would not shake these conclusions.

As you know, the struggle between the scientific spirit and the religious *Weltanschauung* is not yet at an end; it is still going on under our very eyes today. However little psycho-analysis may make use as a rule of polemical weapons, we will not deny ourselves the pleasure of look-

ing into this conflict. Incidentally, we may perhaps arrive at a clearer understanding of our attitude towards the *Weltanschauung*. You will see how easily some of the arguments which are brought forward by the supporters of religion can be disproved; though others may succeed in escaping refutation.

The first objection that one hears is to the effect that it is an impertinence on the part of science to take religion as a subject for its investigations, since religion is something supreme, something superior to the capacities of the human understanding, something which must not be approached with the sophistries of criticism. In other words, science is not competent to sit in judgment on religion. No doubt it is quite useful and valuable, so long as it is restricted to its own province; but religion does not lie in that province, and with religion it can have nothing to do. If we are not deterred by this brusque dismissal, but enquire on what grounds religion bases its claim to an exceptional position among human concerns, the answer we receive, if indeed we are honoured with an answer at all, is that religion cannot be measured by human standards, since it is of divine origin, and has been revealed to us by a spirit which the human mind cannot grasp. It might surely be thought that nothing could be more easily refuted than this argument; it is an obvious *petitio principii*, a "begging of the question." The point which is being called in question is whether there is a divine spirit and a revelation; and it surely cannot be a conclusive reply to say that the question cannot be asked, because the Deity cannot be called in question. What is happening here is the same kind of thing as we meet with occasionally in our analytic work. If an otherwise intelligent patient denies a suggestion on particularly stupid grounds, his imperfect logic is evidence for the existence of a particularly strong motive for his making the denial, a motive which can only be of an affective nature and serve to bind an emotion.

Another sort of answer may be given, in which a motive of this kind is openly admitted. Religion must not be critically examined, because it is the highest, most precious, and noblest thing that the mind of man has brought forth, because it gives expression to the deepest feelings, and is the only thing that makes the world bearable and life worthy of humanity. To this we need not reply by disputing this estimate of religion, but rather by drawing attention to another aspect of the matter. We

should point out that it is not a question of the scientific spirit encroaching upon the sphere of religion, but of religion encroaching upon the sphere of scientific thought. Whatever value and importance religion may have, it has no right to set any limits to thought, and therefore has no right to except itself from the application of thought.

Scientific thought is, in its essence, no different from the normal process of thinking, which we all, believers and unbelievers, alike, make use of when we are going about our business in everyday life. It has merely taken a special form in certain respects: it extends its interest to things which have no immediate obvious utility, it endeavours to eliminate personal factors and emotional influences, it carefully examines the trustworthiness of the sense perceptions on which it bases its conclusions, it provides itself with new perceptions which are not obtainable by everyday means, and isolates the determinants of these new experiences by purposely varied experimentation. Its aim is to arrive at correspondence with reality, that is to say with what exists outside us and independently of us, and, as experience has taught us, is decisive for the fulfilment or frustration of our desires. This correspondence with the real external world we call *truth*. It is the aim of scientific work, even when the practical value of that work does not interest us. When, therefore, religion claims that it can take the place of science and that, because it is beneficent and ennobling, it must therefore be true, that claim is, in fact, an encroachment which, in the interests of every one, should be resisted. It is asking a great deal of a man, who has learned to regulate his everyday affairs in accordance with the rules of experience and with due regard to reality, that he should entrust precisely what affects him most nearly to the care of an authority which claims as its prerogative freedom from all the rules of rational thought. And, as for the protection that religion promises its believers, I hardly think that any of us would be willing even to enter a motor-car, if the driver informed us that he drove without allowing himself to be distracted by traffic regulations, but in accordance with the impulses of an exalted imagination.

And indeed the ban which religion has imposed upon thought in the interests of its own preservation is by no means without danger both for the individual and for society. Analytic experience has taught us that such prohibitions, even though they were originally

confined to some particular field, have a tendency to spread, and then become the cause of severe inhibitions in people's lives. In women, a process of this sort can be observed to follow from the prohibition against their occupying themselves, even in thought, with the sexual side of their nature. The biographies of almost all the eminent people of past times show the disastrous results of the inhibition of thought by religion. Intellect, on the other hand—or rather, to call it by a more familiar name, reason—is among the forces which may be expected to exert a unifying influence upon men—creatures who can be held together only with the greatest difficulty, and whom it is therefore scarcely possible to control. Think how impossible human society would be if every one had his own particular multiplication table and his own private units of weight and length. Our best hope for the future is that the intellect—the scientific spirit, reason—should in time establish a dictatorship over the human mind. The very nature of reason is a guarantee that it would not fail to concede to human emotions, and to all that is determined by them, the position to which they are entitled. But the common pressure exercised by such a domination of reason would prove to be the strongest unifying force among men, and would prepare the way for further unifications. Whatever, like the ban laid upon thought by religion, opposes such a development is a danger for the future of mankind.

The question may now be asked why religion does not put an end to this losing fight by openly declaring: "It is a fact that I cannot give you what men commonly call truth; to obtain that, you must go to science. But what I have to give you is incomparably more beautiful, more comforting and more ennobling than anything that you could ever get from science. And I therefore say to you that it is true in a different and higher sense." The answer is easy to find. Religion cannot make this admission, because if it did it would lose all influence over the mass of mankind. The ordinary man knows only one *truth*—truth in the ordinary sense of the word. What may be meant by a higher, or a highest, truth, he cannot imagine. Truth seems to him as little capable of having degrees as death, and the necessary leap from the beautiful to the true is one that he cannot make. Perhaps you will agree with me in thinking that he is right in this.

The struggle, therefore, is not yet at an end. The followers of the religious *Weltanschauung* act in accordance with the old maxim: the best

defence is attack. "What," they ask, "is this science that presumes to depreciate our religion, which has brought salvation and comfort to millions of men for many thousands of years? What has science for its part so far accomplished? What more can be expected of it? On its own admission, it is incapable of comforting or ennobling us. We will leave that on one side, therefore, though it is by no means easy to give up such benefits. But what of its teaching? Can it tell us how the world began, and what fate is in store for it? Can it even paint for us a coherent picture of the universe, and show us where the unexplained phenomena of life fit in, and how spiritual forces are able to operate on inert matter? If it could do that, we should not refuse it our respect. But it has done nothing of the sort, not one single problem of this kind has it solved. It gives us fragments of alleged knowledge, which it cannot harmonize with one another, it collects observations of uniformities from the totality of events, and dignifies them with the name of *laws* and subjects them to its hazardous interpretations. And with what a small degree of certitude does it establish its conclusions! All that it teaches is only provisionally true; what is prized today as the highest wisdom is overthrown tomorrow and experimentally replaced by something else. The latest error is then given the name of truth. And to this truth we are asked to sacrifice our highest good!"

Ladies and Gentlemen—in so far as you yourselves are supporters of the scientific *Weltanschauung*, I do not think you will be very profoundly shaken by this critic's attack. In Imperial Austria an anecdote was once current which I should like to call to mind in this connection. On one occasion the old Emperor was receiving a deputation from a political party which he disliked: "This is no longer ordinary opposition," he burst out, "this is factious opposition." In just the same way you will find that the reproaches made against science for not having solved the riddle of the universe are unfairly and spitefully exaggerated. Science has had too little time for such a tremendous achievement. It is still very young, a recently developed human activity. Let us bear in mind, to mention only a few dates, that only about three hundred years have passed since Kepler discovered the laws of planetary movement; the life of Newton, who split up light into the colours of the spectrum and put forward the theory of gravitation, came to end in 1727, that is to say a little more than two hundred years ago; and Lavoisier discovered

oxygen shortly before the French Revolution. I may be a very old man today, but the life of an individual man is very short in comparison with the duration of human development, and it is a fact that I was alive when Charles Darwin published his work on the origin of species. In the same year, 1859, Pierre Curie, the discoverer of radium, was born. And if you go back to the beginnings of exact natural science among the Greeks, to Archimedes, or to Aristarchus of Samos (around 250 B.C.) the forerunner of Copernicus, or even to the tentative origins of astronomy among the Babylonians, you will only be covering a very small portion of the period which anthropology requires for the evolution of man from his original ape-like form, a period which certainly embraces more than a hundred thousand years. And it must not be forgotten that the last century has brought with it such a quantity of new discoveries and such a great acceleration of scientific progress that we have every reason to look forward with confidence to the future of science.

It has to be admitted that the other objections are valid within certain limits. Thus it is true that the path of science is slow, tentative and laborious. That cannot be denied or altered. No wonder that the gentlemen of the opposition are dissatisfied; they are spoilt, they have had an easier time of it with their revelation. Progress in scientific work is made in just the same way as in analysis. The analyst brings expectations with him to his work, but he must keep them in the background. He discovers something new by observation, now here and now there, and at first the bits do not fit together. He puts forward suppositions, he brings constructions to one's aid, and gives them up if they are not confirmed, he must have a great deal of patience, must be prepared for all possibilities, and must not jump at conclusions for fear of their leading him to overlook new and unexpected factors. And in the end the whole expenditure of effort is rewarded, the scattered discoveries fall into place, and he obtains an understanding of a whole chain of mental events; he has finished one piece of work and is ready for the next. But the analyst is unlike other scientific workers in this one respect, that he has to do without the help which experiment can bring to research.

But the criticism of science which I have quoted also contains a great deal of exaggeration. It is not true to say that it swings blindly from one attempt to another, and exchanges one error for the next. As a rule, the man of

science works like a sculptor with a clay model, who persistently alters the first rough sketch, adds to it and takes away from it, until he has obtained a satisfactory degree of similarity to some object, whether seen or imagined. And, moreover, at least in the older and more mature sciences, there is already a solid foundation of knowledge, which is now only modified and elaborated and no longer demolished. The outlook, in fact, is not so bad in the world of science.

And finally, what is the purpose of all these passionate disparagements of science? In spite of its present incompleteness and its inherent difficulties, we could not do without it and could not put anything else in its place. There is no limit to the improvement of which it is capable, and this can certainly not be said of the religious *Weltanschauung*. The latter is complete in its essentials; if it is an error, it must remain one for ever. No attempt to minimize the importance of science can alter the fact that it attempts to take into account our dependence on the real external world, while religion is illusion, and it derives its strength from the fact that it falls in with our instinctual desires.

I must now go on to mention some other types of *Weltanschauung* which are in opposition to the scientific one; I do so, however, unwillingly, because I know that I am not competent to form a judgment upon them. I hope, therefore, that you will bear this confession in mind in listening to what I have to say, and that if your interest is aroused you will go elsewhere for more trustworthy information.

In the first place, I ought at this point to name the various philosophical systems which have ventured to draw a picture of the world, as it is reflected in the minds of thinkers whose eyes are as a rule turned away from it. But I have already attempted to give a general characterization of philosophy and its methods, and I believe I am more unfitted than almost any one to pass the individual systems under review. I shall ask you, therefore, instead to turn your attention to two other phenomena which, particularly in these days, cannot be ignored.

The *Weltanschauung* to which I shall first refer is, as it were, a counterpart of political anarchism, and may perhaps have emanated from it. No doubt there have been intellectual nihilists of this kind before, but at the present day the theory of relativity of modern physics seems to have gone to their heads. It is true that they start out from science, but they succeed in forcing it to cut the ground from under

its own feet, to commit suicide, as it were; they make it dispose of itself by getting it to refute its own premises. One often has an impression that this nihilism is only a temporary attitude, which will only be kept up until this task has been completed. When once science has been got rid of, some kind of mysticism, or, indeed, the old religious *Weltanschauung*, can spring up in the space that has been left vacant. According to this anarchistic doctrine, there is no such thing as truth, no assured knowledge of the external world. What we give out as scientific truth is only the product of our own needs and desires, as they are formulated under varying external conditions; that is to say, it is illusion once more. Ultimately we find only what we need to find, and see only what we desire to see. We can do nothing else. And since the criterion of truth, correspondence with an external world, disappears, it is absolutely immaterial what views we accept. All of them are equally true and false. And no one has a right to accuse any one else of error.

For a mind which is interested in epistemology, it would be tempting to enquire into the contrivances and sophistries by means of which the anarchists manage to elicit a final product of this kind from science. One would no doubt be brought up against situations like the one involved in the familiar example of the Cretan who says that all Cretans are liars. But I am not desirous, nor am I capable, of going deeper into this. I will merely remark that the anarchistic theory only retains its remarkable air of superiority so long as it is concerned with opinions about abstract things; it breaks down the moment it comes in contact with practical life. Now the behaviour of men is guided by their opinions and knowledge, and the same scientific spirit which speculates about the structure of the atom or the origin of man is concerned in the building of a bridge that will bear its load. If it were really a matter of indifference what we believed, if there were no knowledge which was distinguished from among our opinions by the fact that it corresponds with reality, then we might just as well build our bridges of cardboard as of stone, or inject a tenth of a gramme of morphia into a patient instead of a hundredth, or take tear-gas as a narcotic instead of ether. But the intellectual anarchists themselves would strongly repudiate such practical applications of their theory.

The other opposing *Weltanschauung* is to be taken far more seriously, and in this case I very deeply regret the insufficiency of my

knowledge. I dare say that you know more about this subject than I do and that you have long ago taken up your position for or against Marxism. The investigations of Karl Marx into the economic structure of society and into the influence of various forms of economic organization upon all departments of human life have, in our day, acquired an authority that cannot be denied. How far they are right or wrong in detail, I naturally do not know. I gather that it is not easy even for better informed people to decide. Some of the propositions in Marx's theory seem strange to me, such as that the evolution of forms of society is a process of natural history, or that the changes in social stratification proceed from one another in the manner of a dialectical process. I am by no means certain that I understand these statements rightly; moreover, they do not sound *materialistic* but like traces of the obscure Hegelian philosophy under the influence of which Marx at one time passed. I do not know how I can throw off the view which I share with other laymen, who are inclined to trace back the formation of classes in society to the struggles which went on from the beginning of history between various human hordes. These hordes differed to a slight degree from one another; and it is my view that social differences go back to these original differences of tribe or race. Psychological factors, such as the amount of constitutional aggressiveness and also the degree of cohesion within the horde, and material factors, such as the possession of better weapons, decided the victory. When they came to live together in the same territory, the victors became the masters and conquered the slaves. There is no sign in all this of natural laws or conceptual modifications; on the other hand, we cannot fail to recognize the influence which the progressive control over natural forces exerts on the social relationships between men, since men always place their newly won powers at the service of their aggressiveness, and use them against one another. The introduction of metals, of bronze and iron, put an end to whole cultural epochs and their social institutions. I really believe that gun-powder and fire-arms overthrew chivalry and the domination of the aristocracy, and that the Russian despotism was already doomed before the war was lost, since no amount of in-breeding among the ruling families of Europe could have produced a race of Tsars capable of withstanding the explosive force of dynamite.

It may be, indeed, that with the present economic crisis which followed upon the Great War, we are merely paying the price of our latest triumph over nature, the conquest of the air. This does not sound very convincing, but at least the first links in the chain of argument are clearly recognizable. The policy of England was based on the security guaranteed by the seas which encircle her coasts. The moment Blériot flew over the Channel in his aeroplane, this protective isolation was broken through; and on the night on which, in a time of peace, a German Zeppelin made an experimental cruise over London, war against Germany became a certainty.<sup>1</sup> Nor must the threat of submarines be forgotten in this connection.

I am almost ashamed of treating a theme of such importance and complexity in such a slight and inadequate manner, and I am also aware that I have not said anything that is new to you. I only wanted to call your attention to the fact that the factor of man's control over nature, from which he obtains his weapons for his struggle with his fellow-men, must of necessity also affect his economic arrangements. We seem to have travelled a long way from the problems of a *Weltanschauung*, but we shall soon come back to the point. The strength of Marxism obviously does not lie in its view of history, or in the prophecies about the future which it bases upon that view, but in its clear insight into the determining influence which is exerted by the economic conditions of man upon his intellectual, ethical, and artistic reactions. A whole collection of correlations and causal sequences were thus discovered which had hitherto been almost completely disregarded. But it cannot be assumed that economic motives are the only ones which determine the behaviour of men in society. The unquestionable fact that different individuals, races, and nations behave differently under the same economic conditions, in itself proves that the economic factor cannot be the sole determinant. It is quite impossible to understand how psychological factors can be overlooked where the reactions of living human beings are involved; for not only were such factors already concerned in the establishment of these economic conditions, but, even in obeying these conditions, men can do no more than set their original instinctual impulses in motion—their self-preservative instinct, their love of aggression, their need for love, and their impulse to attain

pleasure and avoid pain. In an earlier lecture, we have emphasised the importance of the part played by the super-ego, which represents tradition and the ideals of the past, and which will resist for some time the pressure exerted by new economic situations. And, finally, we must not forget that the mass of mankind, subjected though they are to economic necessities, are borne on by a process of cultural development—some call it civilization—which is no doubt influenced by all the other factors, but is certainly equally independent of them in its origin; it is comparable to an organic process, and is quite capable of itself having an effect upon the other factors. It displaces the aims of the instincts, and causes men to rebel against what has hitherto been tolerable; and, moreover, the progressive strengthening of the scientific spirit seems to be an essential part of it. If any one were in a position to show in detail how these different factors—the general human instinctual disposition, its racial variations, and its cultural modifications—behave under the influence of varying social organization, professional activities, and methods of subsistence, how these factors inhibit or aid one another—if, I say, any one could show this, then he would not only have improved Marxism but would have made it into a true social science. For sociology, which deals with the behaviour of man in society, can be nothing other than applied psychology. Strictly speaking, indeed, there are only two sciences—psychology, pure and applied, and natural science.

When at last the far-reaching importance of economic conditions began to be realized, the temptation arose to bring about an alteration in them by means of revolutionary interference, instead of leaving the change to the course of historical development. Theoretical Marxism, as put into effect in Russian Bolshevism, has acquired the energy, the comprehensiveness, and the exclusiveness of a *Weltanschauung*; but at the same time it has acquired an almost uncanny resemblance to what it is opposing. Originally it was itself a part of science, and, in its realization, was built up on science and technology; but it has nevertheless established a ban upon thought, which is as inexorable as was formerly that of religion. All critical examination of the Marxist theory is forbidden; doubts of its validity are as vindictively punished as heresy once was by the Catholic Church. The works of Marx, as the source of revelation, have taken the place of the Bible and the Koran, although they are no freer from

<sup>1</sup> I was informed of this in the first year of the war on trustworthy authority.

contradictions and obscurities than these earlier holy books.

And although practical Marxism has remorselessly swept away all idealistic systems and illusions, it has nevertheless developed illusions itself, which are no less dubious and unverifiable than their predecessors. It hopes, in the course of a few generations, so to alter men that they will be able to live together in the new order of society almost without friction, and that they will do their work voluntarily. In the meantime, it moves elsewhere the instinctual barriers which are essential in any society, it directs outwards the aggressive tendencies, which threaten every human community, and finds its support in the hostility of the poor against the rich, and of the hitherto powerless against the former holders of power. But such an alteration in human nature is very improbable. The enthusiasm with which the mob follow the Bolshevik lead at present, so long as the new order is incomplete and threatened from outside, gives no guarantee for the future, when it will be fully established and no longer in danger. In exactly the same way as religion, Bolshevism is obliged to compensate its believers for the sufferings and deprivations of the present life, by promising them a better life hereafter, in which there will be no unsatisfied needs. It is true that this paradise is to be in this world; it will be established on earth, and will be inaugurated within a measurable time. But let us remember that the Jews, whose religion knows nothing of a life beyond the grave, also expected the coming of the Messiah here on earth, and that the Christian Middle Ages constantly believed that the Kingdom of God was at hand.

There is no doubt what the answer of Bolshevism to these criticisms will be. "Until men have changed their nature," it will say, "one must employ the methods which are effective with them today. One cannot do without compulsion in their education or a ban upon thinking or the application of force even to the spilling of blood; and if one did not awake in them the illusions you speak of, one would not be able to bring them to submit to this compulsion." And it might politely ask us to say how else it could be done. At this point we should be defeated. I should know of no advice to give. I should admit that the conditions of this experiment would have restrained me, and people like me, from undertaking it; but we are not the only ones concerned. There are also men of action, unshakable in their convictions,

impervious to doubt, and insensitive to the sufferings of anyone who stands between them and their goal. It is owing to such men that the tremendous attempt to institute a new order of society of this kind is actually being carried out in Russia now. At a time when great nations are declaring that they expect to find their salvation solely from a steadfast adherence to Christian piety, the upheaval in Russia—in spite of all its distressing features—seems to bring a promise of a better future. Unfortunately, neither our own misgivings nor the fanatical belief of the other side give us any hint of how the experiment will turn out. The future will teach us. Perhaps it will show that the attempt has been made prematurely, and that a fundamental alteration of the social order will have little hope of success until new discoveries are made that will increase our control over the forces of nature, and so make easier the satisfaction of our needs. It may be that only then will it be possible for a new order of society to emerge which will not only banish the material wants of the masses, but at the same time meet the cultural requirements of individual men. But even so, we shall still have to struggle for an indefinite length of time with the difficulties which the intractable nature of man puts in the way of every kind of social community.

Ladies and Gentlemen—Let me in conclusion sum up what I had to say about the relation of psycho-analysis to the question of a *Weltanschauung*. Psycho-analysis is not, in my opinion, in a position to create a *Weltanschauung* of its own. It has no need to do so, for it is a branch of science and can subscribe to the scientific *Weltanschauung*. The latter, however, hardly merits such a high-sounding name, for it does not take everything into its scope, it is incomplete, and it makes no claim to being comprehensive or to constituting a system. Scientific thought is still in its infancy; there are very many of the great problems with which it has as yet been unable to cope. A *Weltanschauung* based upon science has, apart from the emphasis it lays upon the real world, essentially negative characteristics, such as that it limits itself to truth and rejects illusions. Those of our fellow-men who are dissatisfied with this state of things and who desire something more for their momentary peace of mind may look for it where they can find it. We shall not blame them for doing so; but we cannot help them and cannot change our own way of thinking on their account.

GREAT BOOKS  
OF THE WESTERN WORLD
